WARREN, EDWARD, M.D., Newton Lower Falls.  
WATERMAN, THOMAS, M.D., Boston.  
WEBBER, SAMUEL G., M.D., Boston.  
WELLS, T. SPENCER, London, Eng.  
WHITE, JAMES C., M.D., Boston.  
YOUNG, ALEXANDER, Esq., Boston.

# INDEX TO THE THIRD VOLUME.

- ABDOMINAL** aorta, compression of, 27  
**Abortion**, criminal, 368  
**Abscess** near the rectum and fistula in ano, 70  
**Académie des Sciences**, experiments at, 139  
**Acid**, chronic, 304  
**Acid medicines**, plea against the indiscriminate exhibition of, 136  
**Adulterations**, chemical, 460  
**Advertisement**, a New York, 15  
**Air**, analyses of, 72  
**Albuminuria**, chronic, of a benign character, 103 ; puerperal mania, &c., 112 ; during pregnancy, 112 ; convulsions after delivery, 113 ; with hypertrophy of the spleen and anasarca, 439  
**Alimentary canal**, abuse of the, 297  
**Amaurosis**, cerebral, 73, 150, 232  
**Amblyopia** potatorum, 156  
**Amenorrhœa**, remarkable case of, 307  
**American Association for the Advancement of Science**, 328  
**American Medical Association**, annual meeting in New-Orleans, 66, 85, 88, 164, 180, 213, 216, 265, 283, 298  
**Amherst College**, physical culture in, 425  
**Ammonia**, muriate of, as a remedy, 387  
**Ammoniaemia**, a new disease, 264  
**Amory**, Dr. Robert. Atropine, 89  
**Amputation**, spontaneous, in utero, 409  
**Anæsthesia**, of the skin, by carbonic acid, 11 ; action of on the blood corpuscles, 160  
**Anæsthetics**, M. Claude Bernard on the action of, 419  
**Andine Heights**, sanitary character of, 30  
**Aneurism**, popliteal, rapidly cured by manipulation, &c., 13 ; of the innominate artery, 239 ; subcutaneous injection of ergot, 380  
**Anus**, imperforate, with opening into the vagina, 79  
**Aphasia**, case of, 43 ; paper on, 105  
**Apollonio**, N. A. Note from, 428  
**Arnica**, poisoning by, 428  
**Argento-albuminuria**, 27  
**Arsenic**, as a cause of herpes, 286  
**Arteries**, torsion of, 264  
**Ascites**, relieved by copaiha, 442  
**Asphyxia neonatorum**, 180  
**Ataxia locomotor**, 44  
**Atropine**, 89  
**Aural surgery**, clinique in, 128 ; cases, 369  
**Babies**, western, another specimen of, 215  
**Banting's system**, as a cause of Bright's disease, 28  
**Beard**, Dr. George. Neurasthenia, 217  
**Belladonna** in scarlatina, 106  
**Berlin**, Medical School of, 175  
**BIBLIOGRAPHICAL NOTICES**.—  
     Scarlet Fever and its Prevention, 8  
     The Philadelphia System of Obstetrics, 9  
     Essentials of the Principles and Practice of Medicine, 40  
     New Operation for Artificial Hip-joint in bony Anchylosis, 58  
     Compendium of Percussion and Auscultation, 59  
     Treatise on the Diseases of Infancy and Childhood, 79  
     The Preventive Treatment of Scarlet Fever, 97  
     The Dental Cosmos, 99  
     Recovery after passage of an Iron Bar through the Head, 116  
     Treatise on Diseases of the Ear, 136  
     Hand-book of Uterine Therapeutics, 136  
     Atlas to the Pathology of the Teeth, 157  
     Works on Skin Diseases, 189  
     Practical Treatise on the Diseases of Women, 226  
     A Conspectus of the Medical Sciences, 214  
     The Nomenclature of Diseases, 301  
     Treatise on Diseases of the Eye, 320  
     On Long, Short and Weak Sight, and their Treatment by the Scientific use of Spectacles, 315  
     The Surgical Treatment of the Diseases of Infancy and Childhood, 395  
     Surgical Cases, 399  
     Uterine Catarrh frequently the cause of Sterility, 400  
     Dictionnaire Annual des Progrès des Sciences et Institutions Médicales, 437  
     Syphilis and Local Contagious Disorders, 437  
     Secondary Degenerations of the Spinal Cord, 437  
     Bigelow, Dr. Henry J. Cleft palate, 1  
     Bile, the function of unknown, 141  
     Birth of an extraordinarily large child, 122  
     Births, limitation of, in France, 87  
     Bladder, urinary, rupture of, 10  
     Blake, Dr. C. J. Clinique in aural surgery, 128  
     Blood, the, after electric discharge, 444  
     Blood corpuscles, action of anæsthesia on the, 160 ; discovery of new anatomical feature in, 322 ; Cohnheim on the, 362  
     Boston Lunatic Asylum, 456  
     Boston City Registrar, annual report, 350, 368  
     Boston Society for Medical Improvement, reports of, 5, 38, 78, 173, 203, 376  
     Boston City Hospital, reports of cases, 54, 239, 257 ; appointments, 88 ; report of the trustees, 164  
     Boston Obstetrical Society, reports of the, 111  
     Brain, non-malignant abscess of the, 424  
     Brain, injuries of the, and their consequences, 111 ; extraordinary recovery from injury, 230 ; weight of the, 231  
     Bright's disease, prognosis of, 476  
     Bromide of potassium, in epilepsy, 110 ; in tetanus, 452  
     Brown, Dr. Francis H. Combined wire speculum and retractor, 418 ; the Children's Hospital, 176  
     Brown-Séquard, Dr., 15, 71, 213, 414 ; on the seat

- of epilepsy, 44; rapid change of color in human hairs, 345; arrest of convulsions, 345
- Buckingham, Dr. C. E. Membranous croup, 18; pin-worms, their homoeopathic treatment, 169, 352
- Butler Hospital for the Insane, 88, 144
- Calculus, intestinal, a case of, 202; salivary calculi, 324
- Campbell, Dr. W. H. Reports of Norfolk District Medical Society, 6
- Camphor, danger of strong doses, 248
- Cancerous degeneration of kidney, 249
- Cancerous tumor, reported cure of, by gastric juice, 229
- Canities, sudden, 443
- Capron, Dr. George. Remarks upon a class of obstetrical cases, 197
- Carbolic acid, 176, 196; in the treatment of ulceration of the os uteri, 178; accidentally taken as an enema, 164; antidote to, 216; and hospital mortality, 262
- Carbonic oxide, 68
- Carbuncle, clinical lecture on the treatment of, 142
- Carolina sisters, the, 414, 457
- Cataract, congenital double, 57; double, 58
- Cattle disease, 78
- Cerebellum, functions of the, 25; researches on the physiology of the, 260; of the insane, 479
- Cerebral amaurosis, 73, 150, 222
- Cerebroscopy, new researches in, 479
- Cerebro-spinal fever, 216
- Cerebro-spinal meningitis, 11; case resembling, 174
- Cervix uteri, surgery of the, 179
- Charity medicine, abuse of, 382
- Charlatany, choice specimen of, 423
- Cheever, Dr. D. W. Boston City Hospital Reports, 132
- Chemical adulterations, 460
- Chloride of gold in microscopy, use of, 292
- Chloroform, paralysis following the use of, 213
- Cholera vs. cleanliness, 451
- Chorea, nature and treatment of, 101
- Choroid, tuberculosis of the, 163
- Chromic acid, 304
- Cinchona tree, cultivation of in California, 72; in Jamaica, 307
- Clarke, Dr. E. H., departure of, for Europe, 216
- Cobb, Dr. Albion. Case of herpes zoster, 94
- Cod liver oil, etherized, 123
- Cohnheim's alleged discovery, 26
- Coloboma iridis, downwards in both eyes, 157
- Congestion, Cohnheim on, 362
- Conjunctiva, peculiar cystic tumor of the, 156
- Connecticut Hospital for the Insane, Annual Report, 351
- Consumption, in Massachusetts, 119; as affected by soil moisture, 421
- Convulsions, arrest of, 315
- Coralline, 413
- Cornua, suppurative inflammation of the, 35; nerves of the, 229; cut through, 57
- Cotting, Dr. B. E. Medicinal plants indigenous at Para, useful in dysentery and diarrhoea, 110; the pathological anatomy of surgical stumps, 233, 253
- Cowan, Dr. F., valedictory address, 113
- Craniotomy and Cæsarean section, 29
- Criticism, 475
- Croup, membranous, 18; tracheotomy in, 258
- Cutaneous horn, 216
- Cutaneous diseases, 381
- Cutter, Dr. E. Removal of growths upon vocal chords, 37
- Cyst, serous, of the rectum, 297
- Dalton, Dr. J. C. Letter to the editor, 25; trichina spiralis, 241
- Damon, Dr. Howard F. Reports of Obstetrical Society of Boston, 111
- Death in the vat, 124; sudden, 183
- Della fomesa tarantola, 128
- Dentition, third, 215
- Derby, Dr. George. Bromide of potassium in tetanus, 452
- Derby, Dr. Hasket. Treatment of diseases of the lachrymal sac, 108
- Diabetes, cured by peroxide of hydrogen, 248
- Diagnostic expedients of J. Marion Sims, 83
- Diapason, the normal, 84
- Discoloration, extensive congenital, of the human body, 423
- Diseases, nomenclature of, 479
- Dispensary, Boston, 13, 106, 179
- Distichiasis operation, 58
- District of Columbia Medical Society, dedication of hall of, 32; and colored doctors, 407
- Doctorate of medicine, the, 301
- Double consciousness, 117
- Draper, Dr. F. W. Boston City Hospital Reports, 239, 257; the physiological and therapeutic relationships of ergot of rye, 309, 337, 357
- Drugs, the traffic in, 401
- Dunglison, Prof. Robley, death of, 179
- Dwight, Dr. Thomas, Jr. Use of chloride of gold in microscopy, 292
- Dysentery and diarrhoea, medicinal plants useful in, indigenous at Para, 110
- Ear, discharge of blood and serum from, 192; syringe for the, 185
- Editors, American Medical Association of, 263
- Education, medical, in Paris, 31; preparatory, 181
- Ellis, Dr. Calvin. Letter from, at Berlin, 175
- Embolism, of external iliac, followed by gangrene, &c., 269; a case of, with remarks, 445; of the subclavian artery, 451
- Enucleation, 57; of the eyeball, 36, 169
- Epilepsy, seat of, 45; treatment of, 123; bromide of potassium in, 140
- Ergot of rye, the physiological and therapeutic relationships of, 309, 337, 357; subcutaneous injection of, for aneurism, 380
- Erysipelas, traumatic, oil of turpentine in, 15; hereditary, 71; minute anatomy of the skin in, 162
- Essex North District Medical Society, reports of, 131
- Ether, sulphuric, alleged cases of death from, 10; use in membranous croup, 194
- Ether spray, in the reduction of strangulated hernia, 381
- Evidence, medical, 461
- Eye, unusual cases of traumatic injury of the, 94; cases of arrest of development of the, 256; paralysis of motor nerves of the, 274
- Eye-ball, enucleation of the, 36, 169
- Eye-lid, cutaneous horn of the, 17, 32
- Experts, medical, in courts of justice, 356, 461; rights and duties of, 474
- Feeding by the nostrils, 442
- Female doctors, 179
- Female medical schools, advertisements of, 325
- Fisher, Dr. T. W. Insensibility to pain from mental causes, 416
- Fistula in ano, 19
- Fetus, in utero, cries of a, 327; death of, in a household attacked with measles, 393
- Follicular enteritis, a case of, 197

- Forceps, mode of applying the, 395  
 Fossil human remains, discovery of, 30  
 Fracture bed, an improvised, 4  
 Fracture, compound, of lower third of the leg, 454;  
 of patella, 288  
 French, Dr. Samuel P. Perforating gastric ulcer,  
 435  
 Galvanism, an antidote in poisoning, 185  
 Ganglion, inter-carotid, 453  
 Gangrene, hospital, 71; of the lung, 162; from  
 emboli, 304; urinary infiltration in relation to,  
 327  
 Garland, Dr. G. W. Reports of Essex North Dis-  
 trict Medical Society, 131  
 Gas, apparatus for detecting, in rooms, 71  
 Gay, Dr. G. W. Membranous croup, 18  
 Gelsemium sempervirens, galvanism an antidote in  
 poisoning by, 185  
 George, Dr. C. F. An enormous mass of disease  
 formed by cancerous degeneration of kidney, 219  
 German naturalists and physicians, annual congress  
 of, 68, 232  
 Germany, status of medical profession in, 387  
 Gilley, John, remarkable old age, 432  
 Glyco-inosine, 479  
 Graduates in medicine at Yale College, 16; at Har-  
 vard, 425  
 Green, Dr. J. Orne. Case in aural practice, 369  
 Grissolle, death of, 106  
 Hæmoptysis, case of, 70  
 Hæmorrhage, pathogenesis of, 363; exhaustive uter-  
 ine, 433; retinal, 157; traumatic, 105  
 Hair dyes and cosmetics, 72  
 Hairs, human, rapid change of color in, 345, 368  
 Harvard University, medical graduates, 425; its new  
 president, 196; levee of medical faculty, 88  
 Haskins, Dr. A. L. Typhoid fever with perforation  
 of small intestines, 293  
 Hay, Dr. G. Two cases in ophthalmic practice, 35  
 Hay-fever, or rose cold, 125, 170, 185; caused by  
 vibriones, 426  
 Head, injury, extraordinary recovery, 230  
 Health department, internal, superintendent of, 27  
 Heart disease, and the Turkish bath, 427  
 Hernia, strangulated, infusion of coffee in, 12; radical  
 cure of, 195; hypodermic injection of morphia  
 in, 479  
 Herpes, arsenic as a cause of, 286  
 Herpes zoster, case of, 95; in a patient 80 years of  
 age, 289, 312, 341  
 Hip, luxation of, in a young boy, 194  
 Hitchcock, Dr. Alfred. Disease of the supra-renal  
 capsules, 148  
 Holmes, Dr. O. W. Review of the Dental Cosmos, 99  
 Homans, Dr. C. D. Reports of Boston Society for  
 Medical Improvement, 5, 38, 78, 173, 203, 376  
 Homeopathic Convention in Boston, 350, 363  
 Horn, cutaneous, 216; of the eye-lid (with cut) 17,  
 32  
 Horse, discovery of minute fossil, 248  
 Hosmer, Dr. Charles E. Two chronic ulcers of the  
 stomach, 168  
 Hospital, the Children's, 157, 476; appointments  
 at the, 479; Charity, at Jersey City, 16; the Car-  
 ney, 480  
 Hospital Reports. Boston City Hospital, 51, 132,  
 239, 257; Massachusetts Charitable Eye and Ear  
 Infirmary, 57, 156  
 Hydrogenium, a new metal, 16  
 Hydrophobia, in a flock of sheep, 327  
 Icterus, pathological physiology of, 381; and pneu-  
 monia, 46, 83  
 Ileocecal region, disease of the, 424  
 Infants' Hospital, New York, house physician for,  
 176  
 Insane, early treatment of the, 232; auricular hæma-  
 toma of the, 247; cerebellum of the, 479  
 Instruments, steel, plated with nickel, 13  
 International Medical Congress, 40  
 Intestine, recovery from wound of, 377  
 Iridectomy, 58  
 Iron, preparations of, 442  
 Iron bar, passage of, through the head, 116, 263  
 Jackson, Dr. J. B. S. Case of monstrosity, 33;  
 critical remarks on a chemical lecture of Prof.  
 Oppolzer, 136, 226; Carolina sisters, 414, 457  
 Jarvis, Dr. Edward. Mania transitoria, 329, 353  
 Jaws, diseases of the, 165  
 Jeffries, Dr. B. Joy. Translation of cerebral amauro-  
 sis, 73; Massachusetts Charitable Eye and Ear  
 Infirmary, 57, 156; case of herpes zoster ophthal-  
 micus in a patient 80 years old, 289, 312, 341  
 Kessler, Dr. A. Paralysis of the motor nerves of  
 the eye, 274  
 Kidney, degeneration of in an infant, 219  
 Knee, sprain of the, with diastasis, &c., 440  
 Knee-joint, large loose cartilage in the, 67  
 Kneeland, Dr. Samuel. Preparatory medical edu-  
 cation, 181  
 Knight, Dr. F. I. Two cases of paralysis of intrin-  
 sic muscles of the larynx, 49; an addition to Cam-  
 man's double or binaural stethoscope, 221; recov-  
 ery from pneumothorax, occurring in a case of  
 incipient phthisis, 389  
 Kristeller's method, 232  
 Labor, tedious, incision of os and cervix uteri, 250  
 Lachrymal gland, swelling of the, 156  
 Lachrymal sac, treatment of diseases of the, 107  
 Laryngeal tumor, case of, 262  
 Larynx, paralysis of intrinsic muscles of the, 49;  
 traumatic fracture of the, 59  
 Lens, dislocated by a blow, 156  
 Licorice root, fluid extract of, as an excipient for  
 quinia, 180  
 Ligature of divided vessels, new, 260  
 Lincoln, Dr. D. F. Oppolzer's chemical lecture on  
 ulcus rotundum ventriculi, 76; Obstetrical Society  
 Reports, 393  
 Lithotomy, 257  
 Little, Dr. J. Russell. Syringe for the ear, nostril,  
 &c., 185  
 Liver, diseases of the, 141; Dr. Murchison's views  
 of the functions of the, 195  
 Livingstone, Dr., rencontre with a lion, 72; the  
 Paris Academy, 180  
 London, small-pox and vaccination hospital, 261  
 Louisville, Medical Department University of, 388  
 Luce, Dr. L. H. Embolism of the subclavian ar-  
 tery, 451  
 Lumbar colotomy, 121  
 Lunatic Hospital, Boston, Report of Dr. Walker,  
 456  
 Luxation of the hip, in a young boy, 194  
 Lyman, Dr. George H. Embolism of the external  
 iliac, 269  
 Main, Dr. J. T. Galvanism an antidote in poison-  
 ing, 185  
 Maine Medical Association, annual meeting, 388

- Mal-practice, suits for, 287  
 Mania transitoria, 329, 353  
 Mareh, Dr. Alden, death of, 425  
 Marriages, consanguineous, 387  
 Massachusetts, the medical profession in, 305  
 Massachusetts Charitable Eye and Ear Infirmary, reports of cases, 57, 156  
 Massachusetts Medical College, 88, 103, 425  
 Massachusetts Society for the Prevention of Cruelty to Animals, 161  
 Massachusetts Medical Society, annual meeting, 303, 325, 316, 363, 383, 384  
 Massachusetts Dental Society, 308  
 Massachusetts Medical Benevolent Society, 308  
 Massachusetts General Hospital, annual report, 141  
 Maxilla, superior, depression and replacement of, 95  
 McLean Asylum for the Insane, annual report, 230  
 Medical experts, rights and duties of, 461, 474  
 Medicine, the doctorate of, 301  
 Medicines, advertised, 401  
 Meigs, Dr. Charles D., death of, 428  
 Meningo-cerebritis, case of, 11  
 Menstruation, Raciborsky on, 455; an early, 480  
 Mercury, hypodermic injections of, in syphilis, 459  
 Metacarpus in utero, partial spontaneous amputation of, 409  
 Mexico, pathological survey of, 139  
 Meyer, Dr. Ig. K. K. Cerebral amaurosis, 73, 150, 222  
 Microscope, use of in sterility, 41  
 Microscopy, chloride of gold in, 292  
 Middlesex North District Medical Society, annual meeting, 278  
 Middlesex South District Medical Society, annual meeting, 263; reports of, 297  
 Midwifery, operative, Dr. Barnes's lectures on, 407  
 Models, elastic anatomical, 306  
 Monstrosity, case of, 33  
 Morphia, hypodermic injection of, in strangulated hernia, 479  
 Munde, Dr. Paul. Report of a case, 409

### CLEFT PALATE.

EXTRACT FROM A CLINICAL LECTURE DELIVERED AT  
THE MASSACHUSETTS MEDICAL COLLEGE, HARVARD  
UNIVERSITY, DEC. 21, 1863.

By HENRY J. BIGELOW, M.D., Professor of Surgery.

[Reported by HENRY H. A. BEACH, M.D.]

In showing a plaster cast of a cleft palate recently operated upon, I would direct attention to a mechanical expedient for aiding union of the palate in the operation of staphylorrhaphy, first employed, so far as I know, in this case. Before doing so, it may be well briefly to review this deformity and the operation for its relief. The cleft may be median or lateral. It is either a continuation of a hare-lip, or exists independently. In the latter case it may involve both the hard and soft palate; or only the soft palate may be affected—and in cases very favorable for operation, to an inconsiderable degree. The result of this deformity is chiefly noticed in the nasal intonation of the voice, to correct which various expedients have been proposed. The name of the late Dr. J. Mason Warren is associated in this community with many of our earlier operations, and I think that to him is fairly due the original suggestion of freely liberating the soft palate by dissecting it from its upper attachments, before drawing together the margins thus liberated. This is perhaps the great improvement of the modern operation.

I am not aware that Dr. Warren described the anatomy of the parts thus detached. This was afterwards done by Mr., now Sir Wm. Fergusson, who, examining the cleft palate of a dead child, showed that this malformation involved a contraction of the levator palati, and sometimes other muscles. I do not know that this distinguished surgeon detached the flaps in a way which practically differed from that repeatedly accomplished by Dr. Warren, but having described anatomically the parts thus dissected, his name is associated with this feature of the modern

operation. The late Dr. Warren was impressed with the belief that a large majority if not all the subjects of this operation were materially improved, if not cured, of their nasal voice. A case of my own, fifteen or more years ago, led me to scrutinize this point more narrowly, and I was led to the conviction that although a patient occasionally shows a remarkable improvement in speech, the rule is the other way. Neither can improvement be always expected at once, but only after a lapse of sufficient time to allow the parts to become flexible. The case I have just alluded to was that of a young lady, in whom the nasal intonation was very marked, and in whom the only apparent deformity of the palate was a partial cleft of the uvula alone. The palate was ample, and to appearance well under muscular control, and yet this congenital deformity of a bifid uvula was associated with some imperfection in the mechanism of articulation, which months of efforts on her part, even after the fissure was closed by the operation, failed to overcome. This case established the fact that something is wanting for perfect articulation beyond a palate of normal size and appearance; and that although the lateral flaps of a cleft in the soft palate may be attached to each other, often with a result beautiful in appearance, it does not therefore follow that the nervous and muscular action will be perfectly restored. In the case of a wide fissure extending well forward through the bone, the parts are actually insufficient to restore the palate, and then the usual result of the common operation is a band of greater or less width tightly stretched by cicatricial contraction across the palate, bounded behind by a naso-pharyngeal chasm which it is insufficient to close, and in front by a fissure in the bone which still remains. It is difficult to say that the phonation of such patients is not improved a little; they are, indeed, generally inclined to flatter themselves with this belief after an obturator has been adjusted to the bony opening. A patient with palatine fissure, in articulating the words *bad man*, says *man man*, vainly try-

[WHOLE No. 2136.]

ing by facial distortion to occlude the anterior nares; while a patient with nares occluded by a tumor, or a cold in the head, says *bad bad*, or *beautiful bood*, as in the familiar poetry of *Punch*. Between the nasals *m*, *n*, and *ng*, on the one hand, and the labials *p*, *b*, the linguals *l*, *d*, and the gutturals (improperly so called) *k* and *g* hard, made with the the occluded nares, on the other hand, there is a wide difference; and perfect articulation requires the machinery for enunciating, at will, both sets of consonants. This the healthy palate supplies in opening and hermetically closing the posterior nares. Yet there are persons with sound palates who habitually talk through the nose, as the conventional Yankee is said to do. Such persons do not make efficient use of their levator palati and superior constrictor of the pharynx. While we may hope to approximate our patients to the normal condition of such persons, it should be remembered that a very small communication with the nasal fossæ may materially modify the intonation. The nasal quack of the duck, for example, is produced by the reverberation of a comparatively small elastic cavity; and a hole in the human palate a quarter of an inch or even less in diameter, may produce the same result. It cannot be denied, however, that a very marked improvement now and then results from this operation, especially in a favorable case; and in view of this possibility it is certain that patients will continue to demand it at the hands of the surgeon.

The expedient to facilitate union, before alluded to, consists in the employment of a temporary artificial palate, in this instance of hard rubber, to protect the parts during cicatrization. Its use was suggested to me by Dr. Beach as a means of shielding the tongue from metallic sutures, and thereby enabling the surgeon to employ them conveniently during this operation. It also occurred to me that this arrangement would protect the palate from the peristaltic action of the tongue in swallowing, and other involuntary movements which endanger union. It is pretty well established that the success of the modern operation for vesico-vaginal fistula mainly depends upon the use of metallic sutures planted close together, so as to insure close contact of the wound, with an irritation so inconsiderable that they can be left in place from one to two weeks. Similar advantage ought to accrue from their use in the palate. The hard rubber palate here shown was made by Dr. Sheppard, Adjunct Professor in the

Dental School of this University, and fitted so as to cover the whole region occupied by the palate after the operation. It conforms with the arch of the normal palate, leaving an interval of about a quarter of an inch between it and the mucous membrane. Behind, it bends down just far enough not to incommode the tongue, while in front it was in this case keyed in the interstice of the incisors left by the former hare-lip, and laterally attached by a string to a tooth on each side. The whole is made as accurately as if it were a plate for false teeth. A hole near the front admits the nose of a small syringe, by which the interval between the plate and palate was syringed with warm water twice daily. In this case, I cannot doubt that this contrivance was of service. The fissure was wide, reaching forward to the incisors. The flaps were detached well forward from the bone, and seven fine silver stitches were inserted. The plate was not removed for the examination of the parts until the eighth day, when every stitch was found in place and was removed, the union being perfect. During the succeeding week the contracting cicatrices at the margin of the wide fissure of the bony palate drew apart a quarter of an inch of the anterior extremity of the wound, which is less than usual in these cases. The width of the remaining band was about one inch and a quarter, which, considering the size of the palate, is more than we could have expected. I cannot but think that whatever be the operation upon the palate, a more perfect union will be secured by silver sutures thus protected than by the ordinary method.

It remains to notice some of the expedients which have been of late years adopted in connection with this operation. One of the most valuable of these is the so-called "gag" of Mr. T. Smith, of London, a steel instrument by which the jaws are admirably kept open, and the tongue at the same time depressed, so that the parts are fully exposed, and the operation can be performed with great facility under ether, even in young subjects. This one, imported by Dr. Hodges, has been fully tested in the operations of staphylorrhaphy, excision of tonsils, &c., with ether, during the past few months at the Massachusetts General Hospital, and the operation above alluded to was done with its assistance.

Much attention has been directed to the different methods of closing the openings behind and in front of the transverse band of varying width which results from the union of the soft palate in large fissures. This

has been usually effected with an obturator. I have not met with as good results as many writers claim to have obtained, by an operation which consists in simply detaching the soft tissue from the bony margins of the anterior fissure. Of this tissue Langenbeck says that it is "more fragile and more adherent to the periosteum as we approach the gums; in fact, you can only borrow auto-plastic flaps with a chance of success from the posterior part of the mucous membrane, the thickest and least adherent, especially that which covers the horizontal plates of the palatine bones." But there can be little doubt that by detaching this flap we secure a union of the soft palate to a point a little further forward than might otherwise be possible, and so facilitate the subsequent use of an obturator. A later operation, usually attributed to Langenbeck, is said to be much more effectual in closing the anterior fissure. It consists in denuding the whole horizontal bony palate, and uniting the soft tissue thus detached upon the median line. A good idea of this operation may be obtained by supposing two large lateral flaps to be thus formed, from the whole soft and hard palate combined. The tissue is best detached from the bony palate by square or spade-pointed blades inclined to their handles, by which the tough tissue is cleanly dug or hoed from the bone. After starting it, blunt instruments work best. Such flaps are still insufficient, anteriorly, and a lateral incision is therefore made on each side, close to the alveolar processes from the second incisor nearly to the last molar. These incisions stop in front, at the incisors, and behind near the hamular processes, in both cases before reaching the bony canals of the arteries. Thus the arterioles of the flaps are preserved, before and behind, and the flaps are wholly detached from the horizontal bone, except at these three points; the anterior attachment being a pedicle. These incisions are usually made first, and the process of detaching the soft parts is there begun and continued inward toward the median line. When the fissure is wide, and one or both sides of the bony palate vertical, the lateral incisions may not be needed. The anterior fissure thus occluded by obturator or membrane, can have no immediate influence in bad cases upon the pharyngeal opening; although it is quite probable that after a lapse of time the flexible membrane will insure a more flexible soft palate and a better phonation than an unyielding obturator.

M. Passavant, of Frankfort, in a paper

on the means of obviating the nasal intonation in congenital fissures of the bony and membranous palate, &c. (*Arch. Gén. de Méd.*, 1865), after alluding to the inefficiency of present operations to attain this result in a majority of cases, cites a case of much improvement after an operation in which the posterior border of the soft palate was attached to the pharynx behind it, the surfaces being first denuded and then placed firmly in contact by means of sutures. This result, however, was only attained at the expense of a transverse incision of the soft palate, by the gaping of which the palate was brought into contact with the pharynx. I ought here to add that, within a few months, I have attempted this operation in one instance without liberating the soft palate by a transverse incision, and that in this instance the pharyngeal border failed to unite. But it seems not improbable that these and other comparatively recent investigations will lead to some operation to be performed under ether (with the invaluable aid of the dilator above mentioned), which may so far occlude the nasal cavity or shut it off from that of the mouth by a flexible septum, as to insure in bad cases an improvement of the voice, which now only occasionally results from the operation in such cases. It is probable that the hard and soft rubber palate, alleged to afford relief in these cases without operation, would be even more efficient as the results of surgical interference become more complete.

It remains only to describe the common operation. If ether is not to be used, the patient should educate the soft palate to insensibility for a few days by frequently tickling it with a feather. The best way to hold the soft palate for dissection is with double hooks terminating in firm single points, meeting and crossing a little. A single puncture is thus made. Forceps slip, tear and bruise the parts: I divide the muscles until the flaps are free, with scissors doubly curved, on the edge and flat, one for each side, passing the finger occasionally behind the flap, to find what is most tense and unyielding. The edges are now to be pared; this incision bleeds less, and is therefore perhaps best done first. The whole thickness of the edges of the palate should be denuded, and if there be doubt upon this point, owing to the discoloration of the parts, the detached sliver may be floated in water to see if it is of uniform width. Further dissection may be made before or behind at discretion, and the parts brought together by common

small curved needles threaded with silk or wire; then each suture, to facilitate finding it again, has its ends united, and each is drawn in succession through the fissures of a plate of cork, cut like a comb and held on the forehead of the patient. The best needle-holder should have jaws not a quarter of an inch wide, that they may not straighten a curved needle, and not extending half an inch beyond the pivot, that the long handles may secure a firm grip of the needle. The best needles are the smaller sizes of glovers' needle, curved with different bends, the temper being then partially restored and their convex surface flattened by grinding or honing, to prevent them from turning in the forceps. The silk sutures are now tied with common knots; or the wires with a half knot and then a twist, and are to be left in place until union, or as long as they are of any service.

#### AN IMPROVED FRACTURE BED.

By ALBERT SMITH, M.D., Peterborough, N. H.

THE following suggestions, which are only the application of a well-known principle, seem to me to embody an important improvement in the treatment of fractures of the lower limbs, or indeed of any bed-cases. The apparatus is so cheap and easy of construction, as to be within the means of any one; and may be improvised at once, under almost any circumstances in which a patient may be placed. I herewith send you the plan proposed and the mode of using it.

I was called in consultation with Dr. W. D. Chase, of this town, to Mr. Miles Robinson, of Bennington, who had fractured his thigh near the trochanter major, by a fall from his haymow. After the bed had been prepared and the fracture adjusted, and extension applied by a weight over a pulley, I suggested that an apparatus should be constructed for the purpose of raising him from the bed, without injury to the fracture. Those who have the means can procure appliances of this kind, such as Dr. Josiah Crosby's fracture bed, or Dr. W. D. Buck's modification, or others; but the patient was poor, and must have gone without them, unless some cheaper arrangement could have been suggested.

We adopted the following plan:—We directed a frame to be made of the length of the bed and about three feet wide, composed of four pieces of plank, say 3x2 inches in thickness, if of soft wood, secured at the corners, by a mortise or a bolt. Across this frame, from one side to the other, bands of

some strong material, which might be webbing, or bed-ticking, or any other strong cloth, about six inches wide, were carried under the body of the patient, but over the sheet on which he lay, and were fastened securely to the frame on each side, the bands being arranged about six or eight inches apart. This apparatus might remain in its place without any inconvenience, when not used. In order to raise it with the patient on it, a staple was driven into the ceiling over the centre of the bed; a small tackle was hooked upon the staple, and a cord from each corner of the frame was attached to the lower block of the tackle. Assisted by the rope of this tackle the patient can now, with little effort, raise himself as often as may be necessary or desirable.

In this case, the patient had been suffering for years with a painful sciatica of the thigh that was broken, and seemed a most unpromising subject for such a grave injury. But with this apparatus, he is quite free from pain, and seems to be doing as well as any one could at his age (66), it being now nearly four weeks since the accident occurred. In the meanwhile, extension has been kept up without any inconvenience or pain, and there is every prospect of a useful limb, with very little shortening.

This is the second case in which I have used this apparatus with complete success. In the former case, a compound fracture of the tibia, with extensive lacerations of the soft parts, the patient had lain more than forty days on his back, with much suffering and uneasiness. The application of this apparatus surprised and delighted him with the great comfort it afforded, and the ease with which it was used. It was a complete relief to his restlessness; it quieted and soothed him, it gave an opportunity to ventilate and make up his bed as often as desired, it answered all purposes of defecation, and prevented anything like bed-sores, so likely to occur when a patient is long confined to one position.

This may seem a small improvement to suggest to the profession, but it is by such as these that the way is opened to greater and more valuable discoveries. My experience with the mode here suggested has been so successful, that I could not withhold it, however trifling its importance may seem. I hope it will be tried, since the apparatus can be made at so little expense, can be improvised at once, under any circumstances, and is as useful and comfortable as a more expensive apparatus.

## Reports of Medical Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.  
CHARLES D. HOMANS, M.D., SECRETARY.

OCT. 26th.—*Typhoid Fever in Limited Localities.*—Dr. COTTING reported an instance. In Kearsarge avenue is a block of three houses, built of brick six years ago. In the middle house the father was taken sick, and in the course of two weeks four children, who all had typhoid fever and were very sick; in the upper house the fever attacked two adults, and in the lower house four adults, of whom two, a mother and daughter, died; there was one case in each of two houses behind these; all recovered but the two above mentioned. Dr. Cotting had visited in one of these houses during the past ten days, and had found it for ventilation and cleanliness as good as any house could be. After the sickness began, the vault of one of the houses was found to be obstructed, was opened and emptied, but still the disease went on. He could give no explanation of the origin of the attacks, but demurred against the sensational stories promulgated in the community and by the press.

Dr. George Derby thought we were not justified in the conclusion that no local cause existed, because none was found at the first search. In numerous instances an obstructed drain, or a leaky vault, or cesspool, or an accumulation of foul material, which had previously escaped notice, have been revealed by a thorough tearing up of the underground premises. In England such local outbreaks of fever were investigated under Government authority by medical officers. What they have found is reported in the volumes annually published for public information by the medical officers of the Privy Council. The connection between putrifying organic material conveyed to the system by air and water, and fever, seems to be clearly made out. The same connection has been very often traced in this vicinity, as at the Maplewood Institute in Pittsfield, the Clifton House on the Marblehead shore, and in many other instances.

Dr. Derby had witnessed an outbreak of typhoid fever of a very striking character during the war. Military necessity required that one of our regiments, 850 strong, should occupy ground that had been held for several months by the enemy, and which was filled with excrement, and the waste of the camp. Water was drawn from shallow

wells sunk in the midst of this pollution. Three hundred cases of typhoid and twenty-two deaths occurred in this regiment. When they moved to a fresh camp the disease disappeared.

Such evidence seems as positive as that connecting any disease with its cause; syphilis and small pox with contagion, scurvy with the absence of fresh provisions; more positive than that connecting rheumatism with exposure to cold and wet. Neither of these causes always produces the associated disease.

Dr. DERBY thought the popular impression that filth produced fever should be encouraged by our profession.

Dr. READ said a similar series of cases occurred in Lynn some years ago, and it was found that a vault emptied itself into the waters of a well constantly in use for domestic purposes; this was put in order, and the fever ceased.

Dr. CORRING had been able at one time, standing at his own door, to see houses in which eleven cases of typhoid fever existed, counting two in his own house; their origin could not be satisfactorily explained. Once six or seven cases occurred in a light-house dwelling, far from any other residence, having no obstructed drainage, and of course having plenty of good fresh air.

Dr. REXFOLDS said that though these drains were examined, sufficient care might not have been employed, as they frequently proved to be out of order when supposed to be all right.

Dr. JACKSON confirmed what had been remarked by Dr. Cotting.

Dr. WARE thought it a mistake to call the evidence positive when we do not know that the supposed cause produces the disease. In the present state of our knowledge of the nature of typhoid, it is mere coincidence. We know that the same conditions of drainage do not always produce typhoid. And we know that typhoid occurs when there is no such cause to produce it. It is quite as likely that it is something else less conspicuous, and of which we are at present ignorant, which occasions these groups of typhoid within a limited area when there is not much of it in the neighborhood. Dr. Ware had met with three instances of isolated groups of typhoid, one where there were five cases in one house, another in which there were seven cases in one house, another in which there were eighteen cases in a block of two houses. In each instance typhoid was not prevalent in the neighborhood. In neither instance was there any defective drainage, nor nuisance

of any kind about the premises or neighborhood.

The numbers in each of these groups are sufficiently large to make it probable that there was a special cause for their occurrence. But they also show that it is a hasty thing to conclude, that when there happens to be the coincidence of defective drainage, that that is the cause.

Dr. COTTING thought there was something belonging to typhoid fever essential to an attack or spread of the disease, besides emanations from drains, filth, &c. The disease broke out again at Maplewood, a year or so after the cleansing. At Andersonville, filthy enough, certainly, there was none of it, and when brought there it did not spread.

A typhoid fever recently prevailed in Bootle, a suburb of Liverpool, and according to reports seized upon those dwelling in self-contained, airy, and well drained houses, in larger proportion than in others. The usual complaints against water-supply, drainage, filth, &c., were made, but were found to have little or no foundation. "That it had its origin in some more general cause seems proved," says a reporter, "by the wideness of its spread, for not only were Bootle, Waterloo, and Seaford affected, but a fever of the same type prevails largely in Liverpool just now."

Dr. HODGES suggested that as there was probably blood poisoning in this disease, the poison might exist in the atmosphere and be transferred from house to house or person to person, as has been thought to be the case in erysipelas, septicæmia, and pyæmia.

Dr. OLIVER said that during the late war a cavalry regiment encamped on ground near Alexandria, which became gradually saturated with urine, &c., the horses standing up to their ancles in filth; typhoid fever broke out in this regiment, and in no other one of the division. The cases were very numerous, and many of them were fatal. This was the only cavalry regiment in the division, and it was encamped in the immediate vicinity of the infantry regiments and of the batteries of artillery, but on lower ground, where drainage was necessarily bad. Thorough search, by an official, failed to detect any other cause for the outbreak of fever than this accumulation of filth.

Dr. LYMAN said that during the war of the rebellion there were many instances of this kind, but it only proves that low fever will follow the re-occupation of old camping-grounds, which retain the filth, &c., resulting from their former use. A notable in-

stance of this kind was observed at Columbus, Ky., which had been occupied by a confederate army during the year preceding its occupation by the Federal forces.

Nov. 9th. — *Local Origin of Typhoid Fever.* — Dr. MINOT said that he was called in September to a gentleman in Watertown, who was ill with typhoid fever. The patient was convalescent towards the end of October, and was able to come to town for the first time, October 29th. Some days previous to that date, a foul smell was perceived about the house, and the drain was taken up and examined, but nothing wrong was discovered. On the 31st of October, a little boy eight years old, having been complaining for a few days, was taken sick with what proved to be typhoid fever. November 2d, a girl, nine years old, and November 4th, another girl, twelve years old, were taken ill with the same symptoms. A careful search was now made as to the condition of the drain, and it was found that an opening existed between it and an air box which conveyed air from without to a chamber behind the kitchen range and thence to the bath room, so that the foul air had free access to the bath room, and thence to other parts of the house. Nov. 6th, the wife of the gentleman first taken ill, after suffering for a week with headache, went to bed with symptoms of typhoid fever. As some smell was still perceived about the premises, a new search was made, and another opening in the drain was discovered, beneath the wash-room floor. The workman who took up the floor was so much overpowered by the effluvia that he had to be assisted to the outer air.

---

NORFOLK DISTRICT MEDICAL SOCIETY OF MASSACHUSETTS. WM. H. CAMPBELL, M.D., OF ROXBURY, ASSISTANT SECRETARY.

A regular quarterly meeting of the Norfolk District Medical Society, was held at the Phoenix House, Dedham, January 13th, 1869, at 11, A.M.; the president, Dr. Cotting, in the chair.

The records of the preceding meeting were read by the secretary, Dr. Jarvis, and accepted.

Dr. Stone, Jr., of Walpole, related five cases of malignant pustule, in addition to those he had previously reported (Boston Medical and Surgical Journal, Feb. 13th, 1868, p. 19).

There have been in all sixteen cases of this disease in Dr. Stone's neighborhood, of which nine were fatal. All these cases oc-

curred in persons working in, or in some way connected with, a hair-factory in the vicinity.

In some of the cases bacterids were found in the vesicles; in one case, in the blood also.

Dr. Stone thought there could be no doubt that the disease owed its origin to a specific poison. The general symptoms were those of a low form of typhus. He said that the patients derived most relief from hypodermic injections of morphine, administered not so much to allay pain as to quiet gastric disturbances, which were very distressing. (Paper on file for publication.)

Dr. Alden, of Randolph, gave an abstract of a paper on the temperature of sick rooms. To the majority of patients a temperature of 62° to 68° Fahr. will be found most acceptable; but the aged, or the very young, require it somewhat higher. This should be regulated by a thermometer, and not left to the sensations of the nurse or attendants. An open fireplace, with wood fire, secured the best ventilation; but the sheet-iron airtight stove, burning wood, would heat a room more effectively in very cold weather; and was preferable to coal stoves, or even the hot-air furnace. There should, however, be an opening in the chimney near the floor. One in the flue, near the top of the room, guarded by a self-regulating valve, opening to an upward current and closing to a descending one (as used in many London houses), might also be very useful.

A great desideratum would be attained if the experiments proved successful which were understood to be now making—having for their object the construction of a hot-air furnace, whose chamber should be heated by steam-pipes, so that nothing but fresh air could enter or pass through it, the heating apparatus being outside, and kept uniform by a thimble-feeder, and the whole at a reasonable cost.

After the remarks elicited by these two papers the Society, by vote, took up the subject assigned for discussion at this meeting, viz.: "*Precautions obligatory, in the present state of knowledge, to be urged upon members of households attacked with scarlet fever—as regards the family and neighbors, and also attendance at school of the healthy children of such families.*"

Dr. Faulkner, of Jamaica Plain, after some remarks on the uselessness of belladonna as a prophylactic, though still mentioned in the text-books, spoke of the uncertainty of any attempts to prevent the access or spread of scarlet fever. He had seen it appear in a family, without known origin, and take

one only out of six children. In some instances it did not spread when no measures were taken to prevent spreading.

Dr. Martin, of Roxbury, believed that there was no proof that the disease had ever been carried in the clothing of physicians or others visiting the sick, though he was not prepared to say that children should indiscriminately go to school from houses where the disease existed. He was quite certain that convalescent patients should not be permitted to go about as soon as generally allowed, as they were capable of communicating the disease while any desquamation was going on. He once suspected a case to have been induced by a blanket taken from a trunk where it had been deposited from a patient fifteen months previously, but he could hardly believe in such a conveyance.

Dr. Edson, of Roxbury, said that he believed physicians might be the means of communicating scarlet fever, and cited two cases, one in his own family, where he himself had apparently carried the disease. He acknowledged that such cases did not afford absolute proof, as some other mode of access was possible, nevertheless the presumptive evidence was strong.

Dr. Burgess, of Dedham, would not keep children from school, and did not believe in such easy communicability of scarlet fever.

Dr. Stedman, of Jamaica Plain, usually advised children to be kept at home in such cases, though he thought there was little or no danger in their going to school. We must, he said, respect, in some degree, the prejudices of the community.

Dr. Alden, of Randolph, thought it was prudent to keep such children at home for their own sakes. As to communicability, that possibly depended on the severity of the disease or epidemic influences.

Dr. Arnold, of Roxbury, after referring to the various ways of communicating the disease, said that it was very certainly contagious, but the laws of its contagion were not yet thoroughly understood. He was quite sure that he had traced it to clothing. He would not allow well children to go to school from houses infected with this disease; and the sick at home should be isolated.

Dr. Salisbury, of Brookline, thought that the disease often appeared to be carried by well persons, when in reality such persons had sore-throat, and were, in fact, passing through a form of the disease. This form of the disease may occur in those who have had scarlet fever previously.

Dr. Jarvis, of Dorchester, said it was best

to err on the safer side, and to keep the well children at home when the disease was in the house. However, he never knew of an instance of the disease being carried in such a manner.

Dr. Stone, Sen., of Walpole, believed that scarlet fever never arose spontaneously; it was always communicated, and was contagious while desquamation lasted. He confirmed Dr. Salisbury's statement, and related several cases in which the disease seemed to be carried in clothing, but in reality arose from the supposed carrier being affected with sore throat. This sore throat in those protected by previously passing through the disease on being subsequently exposed, was analogous to varioloid after smallpox or vaccination; and was capable of giving the disease to such as were not protected.

Dr. Jones, of Newtonville, formerly of this society, present by invitation, thought that clothing might be a means of communication if contaminated with any of the discharges from mouth or nostrils of the patient, but not otherwise. On full recovery the child should be well cleansed and its clothing washed and aired, before being allowed to mix with others.

The time assigned for adjournment having arrived, further discussion was deferred to another occasion.

At 1½, P.M., adjourned.

## Bibliographical Notices.

---

### *"Scarlet Fever and its Prevention."*

UNDER this title "W. Budd, M.D. Ed., Honorary and Consulting Physician to the Bristol Royal Infirmary," writing on the question of how soon children at boarding schools may be removed to their homes after passing through scarlet fever, says, in the British Medical Journal, Jan. 9th, 1869: "If in fact the patient can be so treated as to cease to be an active source of infection by the time he is able to travel, the difficulty is over." One would think so, surely. "Now," he adds, "if my own experience can be trusted, nothing is easier." Q. e. d.

Then, in seven "simple precautions," in which "handkerchiefs are proscribed" but "a good supply of towels" "always at hand," chlorides are repeatedly insisted on; though some paragraphs after that he says, "experience of the largest and most decisive kind has shown that chlorine in the degree of atmospheric impregnation respir-

able by man has no appreciable influence in preventing the spread of infectious disorders." Again, having suitably deplored that others all "united in the humiliating confession that no definite time could be named in which persons who had gone through this infection could safely mix with others," he condescendingly informs the rest of mankind that:

"According to my own experience, these difficulties and perplexities may be entirely averted by the employment of the simplest precautions. To be successful, these precautions must be put in force early, and must be thoroughly carried out. The first thing to aim at is, to prevent the minute particles, which are the carriers of the poison, from taking wing until they can be disinfected *in situ*. This, I find, can be perfectly effected by simply anointing the surface of the body, scalp included, twice a day with olive oil." "The precise period at which it should be begun varies somewhat, no doubt, in different cases. As early as the fourth day of the eruption, a white efflorescence may often be observed on the skin of the neck and arms, which marks the liberation of the new death-giving brood. This efflorescence should be made the signal for the first employment of the oil. From this time the oiling is continued until the patient is well enough to take a warm bath, in which the whole person, scalp included, is well scrubbed, disinfecting soap being abundantly used during the process. These baths are repeated every other day, until four have been taken, when, as far as the skin is concerned, the disinfection may be regarded as complete." "A week or ten days additional quarantine is, however, seldom objected to; and is on the whole, perhaps, more prudent"—more prudent certainly if, as our author had previously stated, "the process of desquamation, by which this crop is finally cast loose, is a very slow one, lasting for the most part over many weeks."

From these extracts the reader will readily comprehend the scientific exactness of the whole paper. In this respect it does not differ from most of the papers and works on disinfection and "prevention."

It would be interesting to ascertain what proportion of the inhabitants of Bristol have been saved from scarlet fever during the last "twenty years" in which, "in a very wide field," Dr. Budd "has never known the disease to spread in a single instance beyond the sick room" where this method was tried. He admits, however, that there are "unhappily large masses" to whom

"it would be little short of mockery to speak of such measures as I have proposed in connection with them," and "that there are few families that have not at one time or another felt the deadly power" of the disease. Yet with great apparent complacency he avers that "if the measures here suggested were systematically and energetically put in force against this great enemy of man, the annual number of the slain would fall to a very low degree."

Are not such dicta of such stuff as dreams are made of?

The *British Medical Journal* is the accredited organ of the British Medical Association!

X. Y. Z.

*The Philadelphia System of Obstetrics, in twelve parts, fully illustrated; etc.* By Jos. S. LONGSHORE, M.D., Professor of Obstetrics and Diseases of Women and Children in the Philadelphia University of Medicine and Surgery, &c. &c. Philadelphia: University Publication Society, 1868. 8vo. Pp. 800.

Our readers have already seen a notice of a medical publication by Dr. Paine, also of "the Philadelphia University." If curious concerning it, they may refer to the *JOURNAL* for January 14th. The book before us may be said to bear a strong family likeness to that of Dr. Paine. It will be best to let it speak for itself on the subject of its own merits, with which (it is to be hoped) the author is better acquainted than is the profession at large.

In the preface Dr. Longshore says: "Our sole object has been to collect the glittering gems of truth from whatever sources we could make available, and arrange them in a casket that may remain imperishable through all coming times as the truth itself is imperishable." He next informs us that he was induced to enter upon the special study and practice of obstetrics by two cases which fell in his way. The first was one of "most terrific puerperal convulsions, which recovered under his charge after having been abandoned as hopeless by three of the most experienced and distinguished physicians of the neighborhood." The second was one of extreme menstrual derangement, in a young woman who refrained from informing her mother of her disease. "This sad mischief resulted," in his opinion, "from a misdirection of that innate modesty which is the gem of the female character!" He then speaks of the Female Medical College of Pennsylvania, of which he was one of the originat-

ors, himself occupying a professor's chair during the first three courses of "regular medical instructions;" after which his connection with the institution ceased. As to his book—"prepared by request"—it is "different from any other medical text-book extant," in the catholicity and the "broad liberality of thought it inculcates."

In a second preface the author gives a "history of obstetrics," beginning with Adam and Eve, Saturn, Uranos, Jupiter and their consorts, and closing with the University of Pennsylvania. Then comes a chapter (called a "Frontispiece") on *Woman*, which exhibits a peculiarly naïve vulgarity, almost astounding to us, and excellently well suited to the taste of those who are seeking a literary stimulus to morbid sexuality.

In the main body of the work we find a great number of remarkable facts, pervaded by a certain air of romance which inclines us to doubt for a moment the author's credibility.

We are told that the stethoscope was for some time greatly in vogue, but that it has been, to a great extent, superseded by the bare ear, except in some cases of females, where the mammae prevent the direct application of the ear, and where motives of "delicacy" suggest its use. "Aside from such considerations, it possesses no merit, that is not enjoyed by the unassisted ear."

Of the duration of pregnancy he does not treat. He contents himself with the bodily transference of an article contributed to this *Journal* about a year ago, by our own Professor of Obstetrics—an article which claims to be only a list of cases, chiefly valuable as material for the professed statistician. We hardly think their author will agree with Dr. Longshore in his remark "that they are American, which enhances their value with the American student." Science has no nationality, though quackery may have.

Of the erudition which is freely placed at the reader's disposal, we give the following specimens:

"The *os occipitis*, occipital bone, from *trior*, inion, occiput." "Cloaca (from the French *cloaque*, from *cluere*, to purge itself, from *κλυζα*, kluzā, I wash.)" "Gestation (from L. *gestatio*, G. *γῆρα*, phoga, to carry.)" "Chorion, from *χοριον*, korion, "skin," from *χορειν*, korein, "to contain." He cites Van-den-bosh, Lænnec, La Chapell, and others. But to treat briefly a disagreeable subject—The book contains

no evidence of the author's fitness for the position of Professor, even at the University of Philadelphia; its only valuable portions are the selections from other writers which he has made, or caused to be made; and wherever he makes an original observation, it is sure to display conceit based upon ignorance, impudence verging upon arrogance, or a spurious delicacy suggestive of its opposite. And he calls this thing the "Philadelphia System of Obstetrics"! D. F. L.

## Medical and Surgical Journal.

BOSTON: THURSDAY, FEBRUARY 4, 1869.

IN becoming again connected with this JOURNAL, it is our purpose that its Editorial matter shall be, in large share, an abstract of the medical topics and transactions of the day.

We shall return to a former plan of "notices to correspondents"; i. e., mention will be made of all communications received, without allusion to the acceptance or non-acceptance of any of them. The authors of such communications as may, for any reason, be considered unsuited to the purposes of this JOURNAL may definitely ascertain the fact of their rejection by private correspondence. But, we bespeak the forbearance of writers for the delay which sometimes occurs before their articles can take their turn at the press. The publishers stand ready, however, to supply extra pages whenever the accumulation of contributed matter may render it necessary. Papers, therefore, on any and all subjects connected with medicine and surgery are earnestly solicited.

With an array of talent not surpassed, at least, in any other section of the country, the medical men of New England are remarkably shy of the types. Many are the statements, uttered at our Society meetings, which are gems of thought or observation, but which never can be got into print because their authors are too indifferent to write them off for the Secretaries. Years ago, in comparing this with some other portions of the United States, Dr.

Holmes remarked that "the leaving out is in inverse proportion to the yield." There is an abundance of scientific material amongst us. The only difficulty is in bringing it out, and thus preventing it from going to waste. We wish the ice of this Northern reserve might be broken through.

THE *Gazette Hebdomadaire de Médecine et de Chirurgie*, year before last published a statement of M. Giraldès with reference to the report of a Committee of the Boston Society for Medical Improvement, upon certain cases of death attributed (erroneously as considered by the Committee) to anæsthesia produced by sulphuric ether. That journal, we believe, has not yet acknowledged our reply of May 28th, 1868, to the comments of M. Giraldès on our *reclamation* offered December 19th, 1867.

FROM the *Dublin Quarterly Journal of Medical Sciences* (the last number which has been received here, that of November, 1868) we make the following notes. Article XIII. gives a history of *Rupture of the Urinary Bladder*. It describes a case of that lesion which ended in recovery, and in which the peritoneal sac was washed out with tepid water injected through the rent in the organ. The reporter, Dr. Thorp, states that out of upwards of fifty cases of this injury, scattered through the archives of medical societies and journals, there are but three instances of recovery recorded, previous to that related by himself; and in one of those three alleged cases there are doubts of its real nature.

*Apropos* of the remark that an unusually severe form of *paronychia* had latterly prevailed in Dublin, an excellent description of that disease is given, and is accompanied with colored illustrations of the affection.

*Tape-worms* are stated to be of rather rare occurrence in Ireland, where yet the pig is an important inmate of the cabin. *Tænia solium* and *T. mediocanellata* are met with, though the latter is comparatively seldom recognized. Dr. Frazer, however, believes that the *mediocanellata* has often been confounded with the *tænia solium*, and is far more common in the Island

than is generally supposed. He declares that the bothriocephalus is by far the rarest of these entozoa, only the fifth instance of it having been as yet reported in Ireland.

M. Demarquay is quoted as saying of *carbonic acid*, that anæsthesia of the skin, when produced by it, only occurred under the influence of a continuous jet played upon a very limited portion of the body; that introduced into the system by the respiratory organs it does not produce the poisonous effects which have been attributed to it, those effects being due to its admixture with carbonic oxide or other agents; that carbonic acid is simply irrespirable; that in man it seems impossible to produce anæsthesia by breathing it, without danger of asphyxia.

As Nice is one of the fashionable resorts for consumptives, it is worth while to be informed that its climate and peculiarities as a health resort have been done into a *brochure* of 37 pages by Dr. Hughes, Prof. of Surgery in the Royal College of Surgeons of Ireland. Dr. Hughes says that the climate of Nice, which is of a stimulating character, is very beneficial in certain forms of phthisis, in chronic bronchitis, atonic dyspepsia, albuminuria, and "many allied forms of disease;" but that it is "injurious in advanced cases of phthisis (especially where there is a quick pulse, with irritative fever), in irritative dyspepsia," &c. It is asserted, also, that different districts of the town are suitable for different forms of disease, so that patients going there should be warned as to the residences they select. The pamphlet is published by Cooper, of Dublin.

By way of the *Archives Générales*, we learn that Dr. Santesson reports (in the *Journal. f. Kinderkrankheiten*, 1868) that, having injected a few drops of perchloride of iron into an *erectile tumor* in an infant, the child died with convulsion in the space of a few minutes. At the autopsy, there were found voluminous clots in the larger venous trunks, and in the right auricle and ventricle. The author thinks the injection penetrated a vein and produced the clots, and recommends that during such operations the veins connecting with the tumor be compressed.

*Cerebro-spinal Meningitis* was not extinct in Ireland in 1868. The disease, in its present or recent visitation, invaded that country in 1866. The last case we happen to have heard of there was in January, 1868.

In a December number of the London *Medical Times and Gazette*, it was stated that "Palæo-pathology" was recently introduced for the first time by Mr. Busk, at the Pathological Society, by the exhibition of a bone from a fossil rhinoceros showing traces of rheumatism; a repaired fracture in a cave bear; and a diseased pelvic bone, also of *Ursus spelæus*.

Dr. J. G. McKendrick (*Edin. Med. and Surg. Journal*, Dec., 1868) relates a case of fatal "*meningo-cerebritis*," caused probably by exposure to the sun" during the unwonted heat of which our trans-atlantic cousins complained so loudly last summer. At the autopsy, the whole of the posterior half of the left hemisphere was found to be soft and infiltrated with a purulent-looking matter, and the left lateral ventricle was filled with it. The right hemisphere was not so much congested as the left; there was no pus or broken-down substance, but the right ventricle contained dark-looking serum. There was no abscess with definite walls. The patient's speech became defective on the eleventh day of his illness; and Dr. M. draws attention to the fact that it was the *posterior* lobe of the left hemisphere which was chiefly affected, the anterior lobe being "firm and healthy looking, with the exception of the small red spots to be seen on making an incision into the cerebral substance." The reporter alludes here to M. Broca's theory of the seat of articulate language in the *left anterior lobe* of the brain.

Dr. McKendrick refers to the use of "*iodide of potassium*" in this patient, without apparent advantage. He, however, quotes the allegations of Dr. Tanner and others as to its great benefit in apparently hopeless cases of encephalitis when given in large doses—three to eight grains every four or six hours.

In the same *Journal* a case of *placenta prævia* is reported by Dr. Frazer. Hæmorrhage, which was profuse, stopped at once

upon the entire separation of the placenta after the manner of Simpson. The bleeding had been previously checked by the tampon, which was retained till labor pains came on. The child came footling, and was born dead. The mother was extremely exhausted, but recovered, though she remained anæmic in her appearance.

The *Archives Générales de Médecine* for December has an article by Dr. Galewski on *neuritis and peri-neuritis of the optic nerve, and their connection with cerebral affections*. Dr. G. says that among the cerebral affections which induce inflammation of the optic nerve, there are known to him only three kinds which have been verified by autopsies. Those are basilar meningitis, cerebral tumors and abscess of the brain. The *scleroses en plaques*, softening from embolism, locomotor ataxy, &c., on the contrary, give rise only to progressive atrophy of the optic nerve. Cerebral apoplexy sometimes disturbs vision. But this symptom so caused is exceedingly rare, and there is in company with it either congestion, or effusion, or atrophy of the papillary layer. Dr. G. was struck with the constancy with which certain symptoms attend the development of optic neuritis. Thus the abrupt invasion of amblyopia or amaurosis, mydriasis, and the coexistence of the neuritis in the two eyes, are habitual symptoms which he would almost call pathognomic of the cerebral affection. But few exceptions have been found to this rule.

To the ocular signs, Dr. G. adds certain rational symptoms, such as vomiting, constant vertigo, violent pains in the brow or occiput, epileptiform convulsions, paralysis of the seventh, fifth and eighth pairs. Paralysis of the third or sixth pair may also occur, but it is ordinarily monocular when the neuritis is due to basilar meningitis.

In the same number, Dr. Duplay gives a paper on "*congenital tumors of the sacro-coccygeal region*." In that region, he says, a certain number of congenital tumors have been found communicating directly with the rachidian canal. But they are rare. Their structure varies, though they are usually described as *cysto-sarcomata*.

Congenital tumors in the sacro-coccygeal region, having no connection with the ca-

nal, are numerous. They are most frequently situated on the anterior surface of the sacrum and coccyx, and consequently in the pelvic cavity. They are generally elongated in shape, and their size varies from that of a hen's egg to that of the head of a fetus at term and upwards. A few scarcely pass beyond the crotch; while others descend as far as the hams, or even the heels. The tumor is usually fixed to the coccyx by a more or less firm pedicle.

Dr. D. makes five classes of these tumors:—1, cysts; 2, sarcomata and cysto-sarcomata, to which he adds fibromata and cysto-fibromata; 3, lipomata; 4, *tumeurs caudales*; 5, certain tumors of very complex nature.

The children affected with these tumors are usually attenuated, but with some exceptions are well formed. They are often born before their time, and frequently also their death precedes parturition. Of 70 cases of infants born alive with these lesions, 61 died. The death generally took place a short time after birth. Authors allege some few cases of individuals living with these tumors from 20 to 55 years. But the congenital existence of the lesions in these cases is not absolutely proved. The cysto-sarcomata are the most fatal.

Results are quite in favor of operative interference. In 12 extirpations of foetal tumors (tumors involving "foetal inclusion"), there was success in eleven cases and death in one; and in that one there was complication with spina bifida. For the other congenital tumors—cysts, cysto-sarcomata, sarcomata, &c.—in the twenty extirpations performed, there were but three deaths and two doubtful terminations.

The results of other operations upon these tumors—puncture, incision, ligature—have been deplorable. Nine cases of puncture or simple incision were all fatal. One case of puncture, with iodine injection, was successful. The ligature, employed five times, gave three deaths and two "cures."

Dr. Marchand, in the *Nouveau Dictionnaire de Médecine et de Chirurgie*, has collected a sufficient number of cases of *strangulated hernia*, in which an infusion of coffee had appeared to relieve the difficulty, to induce the *London Medical Times and Ga-*

zette to recommend a further trial of the alleged remedy. A half pound of roasted and powdered Havana coffee is to be added to twelve "cupfuls" of boiling water. Of this a cup is to be taken every quarter of an hour till eight cups are taken; after this, half an hour is to elapse between the doses. *Quære.* Is it the hot water, or the coffee which does the work? Or is the apparent effect merely a coincidence?

The same Journal reviews a work by Dr. Wunderlich on the "Temperature of Healthy Man"; and an article by M. Hirtz, entitled *Chaleur dans les Malades*, in the *Nouveau Dictionnaire de Médecine*. Wunderlich says the normal temperature of the axilla may range from 97.3° to 99.5° Fahr., the mean being 98.6. "It does not follow that a normal temperature is indicative of health; but every one is in a diseased state whose temperature is above or below the normal limits." The temperature in diseases, the reviewer goes on to quote, has a definite range, whose limits cannot be exceeded, of 22° or 24° Fahr.; i. e., from 112.5° to about 89.6° Fahr. Save by exception, the morbid limits may be put at 108° and 91.4° Fahr.

It is added that influences which do not affect the temperature in health may act very decidedly in disease, and this mobility of the temperature is an indication of morbid action. Deviations in temperature may be limited to those parts of the body which are the seats of diseased action.

**THE BOSTON DISPENSARY.**—As most of our city readers are already aware, the City Government has erected a spacious structure at the corner of Hawkins and Chardon streets, for the purpose of uniting under one roof the principal charitable associations of Boston, and thereby producing a concentration of action unattainable while their various offices and depots were scattered through the city. Among others it has awarded to the Boston Dispensary three spacious rooms in the basement story fronting on Chardon street, where the managers propose to establish a branch to the Institution, with a daily medical and surgical service, as soon as the necessary arrangements can be made. A new field for charitable as well as profes-

sional effort is thus opened to the members of the medical profession, and we trust that the interests of the sick poor will not suffer through the lack of the voluntary services of a class which has ever been prominent in every scheme for the benefit of the dependent and the suffering.

DR. BUCKINGHAM has shown us some steel instruments which have been plated with *nickel*, giving them somewhat the appearance of German silver. They had lain two or three weeks in a wrapper of vulcanized rubber, and had not been in the least tarnished by the sulphur contained in the rubber. The nickel coating is done at about half the cost of silver plating, by Mr. Remington, 14 Province street, Boston.

THE *London Review* is merry over Dr. Chapman's ice-bag remedy for sea-sickness, after this wise:—

"Nor is this deeply interesting pamphlet without its points of humor. Case XIV. inevitably provokes a smile. On the 23d of May, 1864, Dr. Chapman, being in the tidal train that had left Boulogne for Paris, volunteered to apply the ice-bag to the spine of a gentleman who, having just crossed the Channel, complained of nausea. The doctor took an ice-bag out of his plaid, and placed it along the gentleman's back. The latter felt much better, and "begged to be allowed, if possible, to possess himself of the ice-bag. . . . Having obtained my assent, he promised to write to me a report of his further experience in using the bag; but up to the present time this promise remains unfulfilled." Now, even without assuming, what seems probable, that this gentleman carried off one of Dr. Chapman's ice-bags without paying for it, this is melancholy, and if the gentleman is still living, and if this should meet his eye, it is to be hoped for the credit of human nature, that he will redeem his four-year-old promise.

EXTRACT FROM "A CASE OF POPLITEAL ANEURISM RAPIDLY CURED BY MANIPULATION,\* FLEXION AND DIGITAL COMPRESSION." By GEO. C. BLACKMAN, M.D.—The manipulation of the tumor, as first proposed and

\* "The term given to this paper means a particular manipulation of an aneurism, whereby the fibrin may possibly be so displaced as either in part or in whole to block up the main artery on the distal side of the disease."—*Commencement of Mr. Ferguson's paper, 1857.*

practised by Sir. Wm. Fergusson, having been carried out, Prof. B. [Oct. 22d] flexed the leg strongly upon the thigh, and then requested Prof. Conner and Dr. S. C. Muscroft to keep up firm digital compression upon the femoral artery just below Poupert's ligament. At the end of thirty minutes only a slight thrill could be detected. The digital compression was continued for sixty-eight minutes, when the leg was secured to the thigh by a strong band of adhesive plaster, and the patient was carried to his bed. Prof. B. remarked, that in all probability the digital compression had been sufficient to secure the formation of the clot which was to fill and consolidate the tumor, but to make the matter still more certain, he would continue the flexion treatment for a short time longer.

October 23.—Patient had no sleep in consequence of the severe pain he suffered, although he took  $2\frac{1}{4}$  grains of morphia during the night. It was a noticeable fact, that immediately after the operation, the temperature of the leg and foot became greatly diminished, while the sensibility of the parts was greatly increased. For some hours the foot and leg had a mottled appearance. On the day following the operation, the adhesive plaster was removed and the limb was extended until the leg and thigh were at right angles to each other. This change of position gave the patient great relief, and was maintained by a renewal of the application of the plaster.

October 24.—Pretty comfortable this morning, although occasionally some pain is felt in the knee. Tumor decreasing in size.

October 25.—Rested well last night with  $\frac{1}{4}$  grain of morphia. No pulsation in tumor.

October 26.—Still improving; tumor much diminished in size; no pulsation whatever. Takes at night  $\frac{1}{4}$  grain of morphia.

October 30.—Discharged—cured—the tumor not being more than half of its original size.

On the seventeenth of December, this patient came from his residence in Indiana, to show me the excellent condition of his limb. He stated that for some weeks after leaving for home, he suffered much pain in his leg and foot, and that it was easily affected by the cold. Prof. Conner and Dr. Dodge carefully examined the patient with me, and we were all fully satisfied that the cure was perfect. The tumor was thought to be about one-third its original size. It was quite solid to the touch.—*Western Journal of Medicine.*

EXTRACTS FROM THE LONDON MEDICAL TIMES AND GAZETTE.—We expect to have occasion often to do as we have done to-day, viz., group together a number of quotations from the same or several numbers of this periodical. We have subscribed for its weekly issues to come by mail, and shall thus have prompt access to European medical news:—

In the number for January 2d, 1869, the editor thus describes *Professor Owen's "Conclusions" in the Science of Life.* . . .

But as he advanced in his original researches, and more especially in the task of arranging the osteological department of the Hunterian Museum, he felt himself forced to reconsider the conclusions of Cuvier, to which he had before yielded assent; and he adopted the device of an ideal archetypal vertebrate animal, in order to demonstrate the principle of unity of organization. He holds, therefore, the doctrine of unity of plan, although dominated by and associated with that of adaptation to purpose.

According to the homological doctrines of Owen, a vertebrate animal is a sum of successive segments known as vertebræ—developed under the influence of, as it were, two opposing tendencies; one being the tendency to repetition of similar parts, the other to specialization. The principle of repetition—vegetative or irrelative repetition, as Owen calls it—is characteristic of the lower forms of life, and may be exemplified by the numerous and similar many-jointed terminal divisions of the pectoral limbs of the fishes, thence called Rays; by the multiplicity of similar teeth in the lower vertebrates; and by the multiplied vertebral segments of snakes, eels, and the like. If we compare the five fingers, the teeth, and the vertebræ of man with the like parts in the lower vertebrates, we shall get an idea of specialization—of the advance from the "many and like" parts in the lower to the "few and unlike" parts in the higher, in which each finger, tooth and vertebra can be singled out by a competent anatomist, and designated by its proper name and symbol.

Seeing, then, that every vertebrate animal is formed upon one model, by the special development of segments ideally alike, it follows that animals may have answerable parts, though they have no "answerable functions" to perform; that any animal may have organs, or vestiges of organs, not because they are of (teleological) use to it, but because they belong to the general model; and that all the differences from

lowest to highest are produced by degrees of development of parts common to all. As to the cause of these differences, Owen traces the successive manifestations of vertebrate life and form, not to direct or "miraculous creation," but to a natural law, or secondary cause, "operative in the production of species in orderly succession and progression."

There is one generous and eloquent passage in which Professor Owen expresses his fullest conviction that the production of new species is governed by an intelligent and beneficent Will, which has not only predestined the conditions necessary for each, but has taken care for all as one harmonious whole. "Of all the quadrupedal servants of man, none have proved of more value to him in peace or war than the horse; none have co-operated with the advanced races more influentially in man's destined mastery over the earth and its lower denizens. In all the modifications of the old paleotherian type to this end, the horse has acquired nobler proportions and higher faculties, more strength, more speed, with amenability to bit. No one can enter the saddling-ground at Epsom before the start for 'the Derby' without feeling that the glossy-coated, proudly stepping creatures led out before him are the most perfect and beautiful of quadrupeds. "As such," says Professor Owen, "I believe the Horse to have been predestined and prepared for Man." It is significant that the horse is coeval with the same geologic formations as Man. . . . .

*Oil of Turpentine in Traumatic Erysipelas.*—Professor Lücke, of Bern, relates several cases in proof of the great utility attending the local application of oil of turpentine in traumatic erysipelas, the redness disappearing in two or three days, and the temperature falling in a remarkable manner. This effect was more rapidly produced by rubbing in the turpentine than by merely pencilling with it. The diminution of temperature was observed even in cases in which the erysipelas for a while continued to spread. No local irritation results from the application of the turpentine, the patient only complaining of a temporary feeling of burning. Dr. L.'s account is quoted from the *Berliner Klin. Wochenschr.*, Nov. 9th.

Finally, the same journal has picked up from this side of the water a New York advertisement. "If you really want a pure and unsophisticated family pill, buy Dr. Rumboldt's liver-encouraging, kidney-persuading, silent perambulator. 27 in a box. This pill is as mild as a pet lamb, and as

searching as a small-tooth comb. It don't go fooling about, but attends strictly to business, and is as certain as an alarm clock!"

Scarlatina produced 67 deaths in London during the week ending Dec. 26, and 1380 in the fourth quarter of 1868.

*TEMPERATURE IN TETANUS.*—Wunderlich reports two cases from his own clinique; one of traumatic origin, the other idiopathic. They entered the hospital on the 7th and 10th days, respectively. The temperature in the first case, for three days, ranged from 99.3° to 101.4°; no improvement of consequence occurred, and aconiti tr., in doses rising to forty drops daily, was given during twelve days following. The second case, for nine days, ranged from 98.2° to 100.9°; no special improvement; aconiti tr. fifteen drops daily for thirteen days following. Both cases recovered completely; recovery commencing with the use of the aconite. He infers the temperature of uncomplicated tetanus at its height to be "somewhat above the normal, yet below the limit of actual fever—i.e., between (37.4 and 38.4) 99.3° and 101.1°." A higher temperature would probably show the presence of some complication, or an approaching fatal termination; a return to the normal heat may perhaps show that convalescence has commenced. In the second case a slight intercurrent pneumonia, lasting three or four days, actually raised the temperature, but only to 101.5°. Further observations are needed. The tincture used contained one part of aconite in twelve; having less than one-fourth the strength of the U. S. stronger tincture.—*Archiv der Heilkunde*, 10. Jahrg. 1. Heft. D. F. L.

We are gratified by seeing a monograph which appeared in this JOURNAL (year before last) translated into the German, and making the leading article in a first-class periodical—the *Allgemeine Wiener Medizinische Zeitung* for Jan. 12th, 1869. The paper, entitled Ununited Fracture successfully treated, by Dr. H. J. Bigelow, is done into German by Dr. Richard H. Derby, of this city.

We learn from a private source that Dr. Brown-Séquard has accepted a chair in the Paris Faculty of Medicine. This will not prevent him, we are happy to say, from making occasional visits to this country.

## Medical Miscellany.

### SLEEPING SICKNESS (MALADIE DU SOMMEIL).

—A short article with the above title, by Dumoutier, a surgeon in the French Navy, appears in the *Gazette des Hopitaux*, Oct. 13, 1868. The disease was met with on the coast of Africa, and especially in the territory of Gabo and Congo. There is an irresistible tendency to sleep, accompanied with no suffering, but with a general weakening of the limbs; the gait is uncertain, and the tactile sensibility seems perverted. During the sleep, the faces and urine are voided involuntarily. Intelligence seems unaffected, respiration is normal and digestion regular. The patients are shunned by their companions.

The disease is observed more especially among the slaves or captives from the interior, who have undergone great suffering and performed excessive work with insufficient and bad food—and who are the victims of chagrin, ennui and despair.

Strychnia, tonics, exercise and electricity were employed, all to no purpose.

At two autopsies, no change was found either in the brain, the cord, or their membranes.

CORNELL University is to have a rich collection of shells. Dr. Newcomb, who has been engaged in conchological researches and gatherings for the last thirty-five years, has amassed, it is said, a collection of nearly 5,000,000 specimens, and about 12,000 species with their varieties—all of which have been secured for the new University by Mr. Cornell. The labor of two years by Dr. N. will be required to arrange and mount his shells.

The following graduates of the Medical Department of Yale College received the degree of M.D., at the close of the recent commencement exercises:—George W. Benjamin, M.A., New Haven; David Crary, Hartford; John Morgan, Hadlyme; Byron W. Munson, Seymour; Daniel Poll, Hartford; Gould A. Shelton, Huntington; Hanford Lyon Wixon, New Haven; Luther H. Wood, Ph.B., New Haven. The Silliman prize was awarded to Luther H. Wood. A change in the curriculum of study is under consideration.

THE number of deaths in Glover, Vt., the past year was only eleven, with a population of nearly 1300. Two were males, aged 70 and 94—9 were females, four of them being 68, 70, 87 and 94, two were aged 45 and 58, and one was 18.

A CHARITY HOSPITAL AT JERSEY CITY.—The Common Council of Jersey City recently passed the following ordinance:—

“There shall be appointed by the Common Council four regular practitioners of medicine, and four regular practitioners of surgery, of the city of Jersey City, and members of the Hudson County Medical Society, who shall be known as the Visiting Physicians and Surgeons of the Jersey City Charity Hospital, and they shall constitute a Medical Board. Their appointment shall continue during the pleasure of the Common Council, and their services shall be gratuitous.”

PROF. THOMAS GRAHAM, Master of the Mint in Great Britain, a distinguished chemist, and author of the celebrated “Elements of Chemistry,” has written a letter to Prof. Horsford, of Harvard University, announcing his discovery of “Hydrogenium,” a new metal. Its specific gravity is about 2; its color is white.

### CASE OF CUTANEOUS HORN OF THE EYELID.—(WITH CUT.)

By HENRY L. SHAW, M.D., Boston.

THE following is the history of a cutaneous horn of the eyelid, which although not differing pathologically from those occurring on other parts of the body, would seem from its location and size to deserve a permanent record.

J. C. came to the Mass. Charitable Eye and Ear Infirmary Dec. 17th, 1868. Aged 56. Irish. Laborer. A vigorous looking man; has always been healthy. Parents were long lived; neither they nor any of his relatives have had cancer or any growths similar to the one with which he is troubled. About six years ago, there was noticed on the middle of the free border of the lower lid a small pimple, which slowly increased in size. On its anterior surface there soon appeared a fine, hair-like outgrowth, which he described as having been very hard. This continued to grow, gradually assuming the appearance of a horn, until a year and a half ago, when it was about one inch and a half in length, and about the same in circumference at the base. It then, without any apparent cause, dropped off, leaving the pimple as at first. It had not been troublesome beyond the inconvenience of it, either during its growth or at the time of shedding. It had never been inflamed, and had received no treatment.

The present growth started, in a few days, from the same point as the previous one. It, however, grew more rapidly; and in a few months it attained the same size for which, in the first instance, the growth of years had been required. Since that time it has ceased to grow.

It has been of but little inconvenience till the present winter, when the weight of the horn has produced partial eversion of the lid and consequent displacement of the lacrymal punctum, thus causing considerable trouble from the overflow of tears. The jerking motion given to the horn dur-

ing nictation has given rise to a pricking sensation and fatigue of the lid.

The horn was firmly attached near the middle of the lower lid of the right eye, just below the tarsal cartilage, with which, however, it had no connection. It was curved, and looked not unlike the beak of a bird. It measured, over the superior curve, an inch and three quarters. In circumference at the base, it was an inch and seven eighths. The outer portion, for an inch or more, was of a brownish color, rough, and longitudinally furrowed, very hard, and horny in appearance. The end was blunt, the point having been snipped off with scissors. The inner fourth was more the color of the skin, elastic to the touch, and of about the density of cartilage. The base, when examined from the inside of the lid, had the appearance of being filled with sebaceous matter.

The removal of the horn was effected by making a circular incision around the base, care being taken to avoid the tarsal cartilage and hair-bulbs, and also to preserve as much of the healthy skin as possible. The base was quite firmly imbedded, but was readily separated with the scalpel. It was thought that the edges of the wound, which was circular, might be brought together vertically by a free dissection of the flaps. But on trial this was impracticable, on account of the corrugation and eversion of the lid which it produced. A single stitch was therefore introduced a little below the middle, and the upper portion, triangular in shape, was left to granulate.

The second day, the stitch was removed. The rest of the wound healed very readily.

Jan. 1st, 1869.—The cicatrix is quite small. There is slight eversion of the lid, which may be remedied by a plastic operation, should it increase.

Cases like the above are of extremely rare occurrence. In the works of Stellwag, Wecker, Wells, Mackenzie, and numerous other ophthalmologists, no mention is made of the subject. Haynes Walton, in his admirable work on the Surgery of the Eye, speaks of "having met with a few specimens of inspissated sebaceous matter on the

[WHOLE No. 2137.]

edges of the eyelids, but they have all been small, time being wanting to give them the more marked characteristic horny appearance to which they owe their name." In a monograph entitled *Des Tumeurs des Paupières*, by H. Thomas, reference is made to a case of Ph. Boyer's, cited in *Traité Élémentaire de Pathologie Externe*, by E. Follin. On looking at the original report of the case, however, it was found that the horn was situated upon the cheek, and not upon the lid. In the same work of Thomas, a case of Deval's is also mentioned. But the seat of this tumor is described as being on the brow, and he calls it a wen. We quote his own description of the case:—"Des tumeurs de tout genre peuvent se développer dans la région du sourcil. Une petite tumeur qui y était située et dont je pratiquai l'extraction fournit une concrétion calcaire d'un blanc grisâtre et du volume d'un gros pois." South, in the American edition of Chelius's *Surgery*, says:—"Horns have been observed on the eyelids by Voisin; on the lachrymal caruncle by Chavane; and on the conjunctive coat and tongue by Breschet. The works of the first two authors we have been unable to find. Breschet, when speaking of horns, simply says:—"Ainsi, j'en ai observé sur la langue, sur la membrane conjonctive." He does not mention any cases.

The only case recorded, so far as we have been able to ascertain, of a horn growing from the eyelid, is one to which our attention was drawn by Dr. H. F. Damon, who has investigated the subject with great care. It occurred quite recently, in the practice of Dr. Jonssaume, and is published in a monograph by A. Eloffe, entitled *Histoire Naturelle des Cornes*. We append an abbreviated translation of this case.

There came to my office, in 1865, a pale child, five years of age. The child presented, on the free border of the upper lid of the right eye, a horny appendage, truncated, wrinkled, and from a centimetre to a centimetre and a half in length, and of the size of a pipe-stem. By the aid of lateral traction, I removed the small body without difficulty. It was of the shape of a thimble. The wound was canterized with nitrate of silver, to prevent its reproduction. Some days after, it was canterized again, and it was only cured after the fifth application.

In 1866, the child was presented again, for two similar growths on the upper lid of the other eye.

#### A CLINICAL LECTURE.

MEMBRANOUS CROUP; TRACHEOTOMY; DEATH IN 37 HOURS. OCCURRING IN THE PRACTICE OF C. E. BUCKINGHAM, M.D.

Reported by GEO. W. GAY, M.D.

J. B., aged 7, a smart, healthy little fellow, of healthy history and parentage, got wet, Wednesday, Dec. 16th, 1868. On returning from school, where nothing unusual was noticed, he was dull and languid, and had a slight cough, which was unlike anything ever noticed in him before in its harshness and peculiar ring. He ate a little supper, went to bed, and passed a fair night. On Thursday, the cough was no worse, but his general condition was not improved.

Friday, very much better apparently; almost no cough.

Saturday, thought to be about well, and had a hot bath at night. Hitherto he had complained of nothing, and seemed to the parents to be suffering from an ordinary "cold," and received only the ordinary domestic treatment.

Sunday, Dec. 20th.—Was thought to be worse; in the afternoon, Dr. Buckingham was called to him, and found him as follows:—Pulse 120; resp. about 30; respiratory muscles of chest and abdomen in strong action; tongue dry; right tonsil swollen, red and dry, as was also the rest of the fauces. No membrane to be seen.

R. Morph. sulph. gr. ss.  
Potass. iodidi gr. viij.  
Syr. aurant. cort. q. s.  
ad ℥iiss. M.

Dose, teaspoonful every four hours till quiet.

Monday, Dec. 21st, morning.—Pulse rapid; respiratory muscles in strong action; skin livid; large muco-purulent collections in the fauces, which he expectorates on being told. No membrane in sight. Discontinue R., and give a teaspoonful of syrup of ipecac. every hour.

11, A.M.—Seen by Drs. Buckingham and Cheever. Pulse 140, slightly intermittent; resp. 36; moist râles in both chests; percussion normal; severe spasm of epiglottis, and all external respiratory muscles in strong action. Teaspoonful of syrup of ipecac. every ten minutes till he vomits.

1, P.M.—Has taken medicine regularly, and vomited a little twice. Pulse 144; resp. 36; great muco-purulent expectoration; skin less livid. Continue syrup of ipecac. every fifteen minutes.

9, P.M.—No membrane to be seen in posterior part of pharynx, but a few white

spots, appearing like the secretion of the follicles, are seen on each tonsil. Pulse 140, feeble; resp. 32, and very laborious.

9½, P.M., Dec. 21st.—Operation by Dr. Buckingham, assisted by Dr. Cheever and the writer. Ether administered, with little or no effect upon the respiration. Operation performed in the usual manner. Hæmorrhage moderate. As soon as the trachea was opened, a forcible expiration threw out several strips of a tough, stringy membrane. Tube secured in the trachea, and hæmorrhage ceased. Patient put to bed, with the pulse at 140; resp. 20, easy and regularly irregular—i. e., an interval between every three respirations. The temperature of the room was kept between 72° and 76°.

12.30, A.M., Dec. 22d.—Asleep. Pulse 150, regular, stronger than before the operation; moist tracheal râles; sibilant râles in left lung. Tube lined with a little of a muco-purulent substance, which dries quickly and is difficult to remove. Slight subsultus in forearms. Takes milk freely. Teaspoonful of wine every hour.

3, A.M.—Awake. Urine free (3ij.—3iv.). Pulse 160, a little irregular; resp. 32, quiet and deeper. No cough, and no secretion in the tube. Vesicular respiration in right lung. Subsultus increasing. Strength failing. Continue wine and milk.

8.30, A.M.—Patient seen by Dr. B. Pulse 160, regular; resp. 34; moist râles in trachea and both lungs. No subsultus. Dr. B. ordered a few drops of warm water to be injected into the trachea to loosen the secretion, and the patient to breathe through a moist sponge.

11.30, A.M.—Pulse 142, of fair strength; resp. 26, easy. A little of the secretion is ejected after using the water. No membrane is to be seen. He jumps up with alacrity to take his drink.

2.45, P.M.—Pulse 160, not quite so strong; resp. 52, very laborious, and free from râles in trachea and right lung; left lung full of moist râles. Water in trachea does not loosen the secretion. Skin hot, dry, and livid. Respiratory muscles in strong action and face covered with sweat. Ordered ammon. carb. gr. ij. every two hours.

6.15, P.M.—Sitting up in bed, and eating bread and milk. Tube dry. Pulse and resp. as before. Seen by Dr. B., who ordered a weak solution of common salt to be thrown into the trachea, and the wine to be omitted. Continue ammon. carb. and milk.

1, A.M., Dec. 23d.—Pulse 170 and up-

wards, and difficult to count; resp. 42, more laborious; both lungs full of moist râles. Cannot cough. Urine free. Not so strong as at last report. Ammon. carb. gr. ii. every hour.

7.45, A.M.—Has been pretty quiet since last report; has taken food and medicine regularly. Pulse 148, regular and stronger; resp. 42, regular, but no easier. Has passed a teaspoonful of urine at three different times. No distention of the bladder. Tube dry and clear; has required cleaning only once in six or eight hours. Salt water has lost all effect in softening the secretion. Neck swollen from emphysema. Skin very livid. A little restless. Teaspoonful of prescription of Dec. 20th given.

10.10, A.M.—Skin not quite so livid; resp. 34, no easier. Gets up on his elbow to drink his milk and medicine. Has refused nourishment but once since the operation. Mouth and wound lined with a thin layer of a dry grayish substance. Emphysema extends over chest and abdomen into scrotum. Legs purple.

10.30.—Dead, 37 hours after operation.

*Boston, January 19, 1869.*

## FISTULA IN ANO.

Read before the Suffolk District Medical Society, Dec. 26th, 1868, by JOHN P. ORDWAY, M.D.

PROBABLY no disease to which the human organism is prone, from the days of Hippocrates down to the present time, has developed more diversity of opinion among surgeons, as regards treatment, location, or extent. It is not my purpose in this paper to speak at length of the location of the rectal orifice of the complete fistula, which Desault, and many of the ancient authors, contended would be found sometimes in close proximity to the anus, and at other times at a considerable distance from it, while Ribes, Larrey, Sabatier, Boyer, Richer, and Brunel of Avignon (who wrote a special treatise on fistula in 1783) and others, contended that the orifice was situated just above the external sphincter. Nor will I mention those authors who believed there were no internal or external blind fistulas; but will speak of what seems to me a rational treatment, which experience and careful investigation for the past four years have led me to believe the only true treatment for the radical cure of "fistula in ano."

In doing this, I start with the positive assertion, that in my judgment the knife, so often used by surgeons with salutary

effect in other diseases, should never be used in this. To build up and repair, without destroying, sound tissues and muscles, upon which organs in the immediate vicinity are dependent, should be, it seems to me, the duty of every physician and surgeon. What should we say of the plumber, who, because the waste pipe had burst in some part, should advise opening the entire pipe, so that the filthy contents could spread all around, doing damage to everything with which they come in contact? Would he not rather attend to the locality from which the leakage proceeded?

Now, what is the character of the canal of a complete fistula, and why is it so difficult to cure? The walls of the canal are lined with what Laënnec calls "analogous accidental tissue," sometimes almost cartilaginous. There is also a mucous secreting surface, more or less indurated, and a discharge of pus, or of feculent matter from the bowel. In fact, several cases I have had under treatment have been so callosified that I could trace the extent of the whole canal by external digital examination.

The first thing indicated then, it seems to me, is, to remove the induration of the mucous membrane of the canal. How is this to be done? Certainly not with the bistoury, for you remove nothing by the cut; you merely divide, without destroying the preternatural surrounding tissue. Besides, you destroy the action of the sphincter, turn the whole mass of diseased tissue and cellular structure into one common drain, and then ask nature to assist in healing; while every evacuation from the bowels causes undue irritation, and removes whatever applications may have been made for the cure of the disease, for the time being, which in my judgment is a strong reason why this method of treatment so seldom fails of cure.

What, then, is indicated in the treatment? First, destroy the mucous membrane, and the induration of the fistulous canal by direct applications, either of tents, or through the syringe, governing yourself by the extent of inflammation, and by the feelings of the patient, at the same time using proper antiphlogistic and alterative remedies to assist nature in the cure; never allowing the fistula to heal except from the internal opening, or until the whole character of the discharge has changed. I have tried many remedies for direct application, such as solutions of muriate of iron, sulphate of zinc, carbonate of potash, nitric acid, iodine, chloride of zinc, &c., varying the remedy

according to circumstances, using nothing for any length of time which will destroy healthy tissue, but using such things as tend to remedy the abnormal condition of the parts. The loose character of the cellular structure in the ischio-rectal region, no doubt, to a certain extent prevents the healing of the parts after an abscess.

Should the ligature ever be used?

I take the ground that every case is curable without it; but if used, it has this advantage over the knife, that, if not drawn too tightly, the fibres of the sphincter muscle unite, almost as fast as they are separated, and thus the risk of dividing the muscles and parts at once (perhaps producing permanent injury for life), is avoided. But the ligature should never be applied until the callus is entirely removed. I have tested this manner of finishing up the work of cure in two cases which came under my care, more to satisfy myself, than because I believed a cure could not have been effected without it. In eleven cases of complete fistula; three cases of external blind fistula; and two cases of internal blind fistula, treated by me during the past eighteen months, I have been successful without the ligature.

The five-stranded hair ligatures, of Hippocrates; or packthread besmeared with escharotic, of Celsus; or twisted hair and hog's bristles, of Avicenna; or waxed hempen thread, of Flajoni, or knotted cord of Salicet, might have been of some service, had their employers first prepared the hardened walls of the fistula by direct applications to bring about a change in the character of the secretions. "*Eccentric Compression*," "*Incision*," and "*Excision*" have all had their advocates in ancient times, without any good practical result in support of their theories.

The caustics, too, used by charlatans in the last century, and at the present day, under the guise of secret remedies, might possibly have been of some service, provided they had not been of such extreme potency, as to destroy healthy surrounding parts. There is no doubt in my mind that the theory of direct local applications to the diseased parts is correct; the great point to be gained is, to change the character of those applications from time to time, as circumstances may warrant, and we shall then get good practical results. The same principle will apply to the healing of any chronic ulcer. We have at least this advantage over the charlatan, that we gain time, and accomplish in days that which, if successful at all, he requires weeks to attain.

Should *phthisical patients* be treated? I can see no reason why they should not. It is contended that fistula acts as an *exultery*; that it would be wrong to dry up the outlet of the fountain at the risk of increasing the primary phthisical disease. The arguments often used by writers on this subject, are, that fistula moderates the progress of pulmonary disease; that it is usually caused by the ulceration of tubercles; that the wound rarely heals up, and by its abundant suppuration acts in an injurious manner upon the system; that if by chance the wound should heal, the pulmonary disease rarely fails to become aggravated.

Nélaton says, "I never hesitate to operate unless the affection of the lungs be very far advanced, and in such cases I am unwilling to operate, *not because I think the operation will do harm to the chest, but because the incision does not heal, so that it is not worth while to operate.*"

In this connection, I would say, a patient of mine was cured of a complete fistula, who, when she first came to me, had well-marked phthisical symptoms. After the fistula was healed, her phthisical troubles left her entirely, and she is now in the enjoyment of perfect health.

I should not hesitate in any case of pulmonary disease to use the treatment laid down in this paper, because I believe that oftentimes fistula, through resorption into the general circulation, is the cause of pulmonary trouble, instead of a remedy for it.

Granting that fistulas do sometimes heal spontaneously, it is only by an exception to the rule, and it may be questioned whether the result has not been due to the fact that the constitution of the person possesses recuperative power enough to combat the disease in a natural way.

The advantages of this mode of treatment over the knife, in pulmonary disease, and in fact, in all forms of "fistula in ano," are these.

1st, The avoidance of the subsequent shock of the operation, as the physician can be governed by the feelings of the patient in making the applications. 2d, The immunity from excessive suppuration. 3d, The destruction of the hardened membrane of the canal without injuring surrounding healthy tissues; and 4th, Because the disease generally occurs in persons of unhealthy organism, who have not the power to stand the excessive drain made upon the system by the operation, and who with this treatment are more likely to obtain a perfect cure. I do not believe it is a surgical disease, or that it comes within the province of surgery.

In presenting this communication to my professional brethren, I do it in no spirit of egotism, nor with any desire to break down long established theories, except so far as they seem to me erroneous. I believe no physician who thoroughly tries this method faithfully will be disappointed in the result. I speak with confidence, when I say that experience has proved to me that "Fistula in Ano" can be treated without the knife, in all cases, with better results, and less risk of permanent injury to the patient.

### MALIGNANT VESICLE.

Read before the Norfolk (Mass.) District Medical Society, Jan. 13th, 1869, by SILAS E. STONE, M.D., of Walpole.

UNDER the title of malignant pustule I reported to this Society, last winter, eight cases, which were subsequently published, by request, in the Boston Medical and Surgical Journal, Feb. 13th, 1868, p. 19. I have now five more similar cases, of which the following is a brief synopsis.

CASE IX.—May 20th, 1868. C. B., aged 16. Right side of throat much swollen. Throat sore. Small, dark-brown slough, surrounded by minute yellow vesicles, about an inch below the angle of jaw.

21st.—Nausea noticed.

22d.—Much worse, but has rested some with an opiate. Thirst urgent. Swelling increased, extending to the chest, in front and back. Nausea increased. Pulse 100 and feeble.

23d.—Rested better, with opiate. Nausea less. Has retained some nourishment. Pulse the same.

24th.—Rested without opiate. But little nausea. Has retained all nourishment. Thirst less. Swelling and soreness less. Pulse 84, stronger.

25th.—Slough dry, but not separated. Patient convalescent.

CASE X.—June 15th, 1868. T. C., hair worker, 35 years. Was called on account of swelling of the neck of the patient, and his feeling sick and unable to work. Found him sitting up. Pulse 95. Right side of neck much swollen. Says he has no pimple or sore spot, but on careful search two malignant pustules were found in the hairy scalp, one about an inch below the occipital prominence, and the other three-fourths of an inch above it. The swelling extends down to the shoulder, and within three inches of the apple. Says he was taken sick on Saturday, 13th, with chills and de-

bility. 6, P.M., one dej. at noon. Now has severe pain in abdomen. Tongue not remarkable. Pulse 106. Thirsty and perspiring through the day, which was very hot. Still sitting up.

16th.—Pulse 93, and not as strong. Swelling enormous, down to spine of scapula behind; to the nipples, and three inches to left of sternum in front. No headache; no nausea; no delirium. Thinks he did not sleep four hours. Was restless. Now skin bathed in perspiration. The pustules not materially enlarged. Before evening the case passed out of my hands into that of an irregular practitioner, but I was informed by the wife that the patient vomited most of the next day; suffered greatly from epigastric distress, and died early on the morning of the 18th. Ecchymoses appeared after death. Treatment—tincture of iodine locally, and tonics internally, with nutritious diet.

CASE XI.—Nov. 1868. E. W., 32, widow, and has six children. Came to my house. Has been ailing several days. Noticed a pimple over middle of the sterno-mastoid muscle on Monday, 16th, but kept at work till about an hour before coming to my house. Has had no chills, but does not feel well, and came on account of the swelling of the neck around the pimple, which was not discolored. The swelling was diffuse, but marked, and about three inches in diameter. Pulse 68. The pustule was about the size of a small pea in diameter, and consisted of several yellow vesicles. Neither centre nor base was dark, nor was there any areola.

19th.—Pulse 128. Chill 8, A.M. Restless, dreaming and frightened in night. Slept about one hour. One dejection, yesterday. Swelling increased.

P.M.—Pulse 120. Swelling still increasing. Centre of pustule dark brown, and base of vesicles deep purple. Continuous pain in neck. Blood and serum examined by Dr. R. M. Hodges. Bacterids found in serum, none this time in the blood.

20th. Pulse 90. Slept two hours. Restless, and disturbed with frightful dreams. Has vomited green and frothy matter four times, but nevertheless has retained some nourishment. Has constant pain in head and neck. Size of pustule increased by new vesicles, and is now one inch in length, and one half inch wide. Slough dry and depressed at centre. Swelling of neck increased, extending to top of cheek and down to left breast. Tongue dry at tip. Left tonsil and whole inside of throat swollen. No chill in night. Left lung dull on

percussion throughout. Respiratory murmur less. Moist râles at lower lobe.

P.M.—Vomiting continues. Swelling increases. Voice husky. In swallowing, part of the liquid rejected through nose. Marked epigastric distress. Pulse 100, very compressible. Morphia gr.  $\frac{1}{2}$ .

21st.—Pulse 88. Slept most of night. Vomited but once since seven, P.M., yesterday. Voice better. Countenance cheerful. Tongue clear. No epigastric distress. Pustule increased in width. Now five-eighths of an inch in diameter. No new vesicles. Whole slough dark brown. Swelling softer. Retains nourishment.

P.M.—Dulness continues over whole of left lung; respiratory murmur less audible. Swelling softer, except near pustule, where it is quite firm. Fluid from vesicles turbid and reddish; not clear yellow serum as before. The vesicles have a withered look. No vomiting. Had some refreshing sleep.

22d.—Pulse 75. Slept most of night. Some pain in head and neck. No new vesicles. Bubo at angle of jaw. Line of demarcation perceptible.

27th.—Has continued to improve. Sitting up.

Dec. 4th.—Removed the eschar. The subcutaneous slough was not as defined as the eschar, and has been thrown off in shreds from time to time, until a few days ago. At present the ulcer thus formed has not healed. In this case the bacterids, to which Davaine has called attention, were demonstrated at various times in the serum of the vesicles, but not satisfactorily in the blood, although appearances indicating their presence there were found.

CASE XII.—Dec. 27th, 1867. S. R., 16 years. Works in hair factory. Had been somewhat ill for some days, but had kept at work till six o'clock of the previous evening, and until within a few days had been as well as usual. Did not sleep last night on account of restlessness and epigastric pain. In the morning took salts, which was followed by two dejections. As the pain and distress continued, I was called about five, P.M. Found her in bed, frequently throwing up her arms, tossing from side to side, moaning and sighing. Her mind was perfectly clear, and she even smiled when I spoke to her. There was no pulse at the wrist. Her countenance was of a dusky leaden hue, and, like her hands, was cold and damp. There was some dulness over both backs and mucous râles were heard throughout the lungs. The distress continued with increasing severity until she gradually became unconscious, and died

about half past eight the same evening, three and a half hours after I first saw her. Ecchymoses appeared after death. No post-mortem examination allowed.

\* CASE XIII.—June 20th, 1868. C. P., 16 years. Has been for a short time at work at the hair factory. His mother called in the evening, stating that her boy had been unwell for three or four days, and had remained at home on that account; but during the time had been about house and out of doors. This morning she had given him a purgative. But as this had not operated, and as he had pain in his bowels, she wished to know what to do. I directed castor oil and hot fomentations. At two the next morning I was called. The pain which he located about the umbilicus had continued and increased in severity, although two liquid dejections had occurred. He was in bed, moaning and tossing about, and constantly throwing up his arms. He did not reply when spoken to, and seemed not to hear. The abdomen was flat on percussion; not distended, but the muscles were rigid. The hands and feet were cool, and there was scarcely any pulse at the wrist. He could swallow, but with difficulty. A large serous discharge passed away unconsciously while I was there. He continued to sink, and died at nine the next morning, seven hours after I first saw him.

*Autopsy*, by Dr. Morrill Wyman, of Cambridge, thirty-two hours after death. Rigor mortis well marked. Shoulders, back of neck, head, and ears, quite purple and uniformly so. Eight to ten ounces of clear, yellow serum removed from abdomen. In iliac fossa peritonæum slightly changed, less polished, with a few capillaries somewhat injected. Ecchymosed patches noticed on ilium and cæcum, most marked within three or four inches of ilio-cæcal valve.

In removing intestines the cellular tissue around head of colon, right kidney, and as high up as the liver was emphysematous. The left kidney was pale, but not diseased; the capsule easily separated. The right kidney, on section, gave some rather dark grumous blood; tubuli distinct, and capsule easily separated. The liver was pale, firm, and of natural size—gall bladder distended with bile. The spleen appeared slightly roughened with whitish dots of lymph; otherwise normal. Pancreas presented nothing noticeable.

The ilium at the junction and involving the ilio-cæcal valve, embracing nearly the whole circumference of the intestines, presented a dark purplish-brown portion, with grayish surface, the dark color extending

through all the coats of the intestine. Above this, for the distance of four or five feet, gradually diminishing in intensity, the solitary glands were extremely prominent, like imbedded shot. They were noticed in the cæcum and in the colon. The mesenteric glands leading from the junction of the ilium and cæcum to about three feet up the ilium, were enlarged, from the size of a pea to that of a hickory nut. The larger glands were dark colored externally, quite firm, and at section appeared mottled with gray. The smaller ones were generally pink in different degrees of intensity. The bladder contained four or five ounces of clear, yellow urine. Stomach not opened.

The lungs were generally soft, and crepitated.

The heart, normal, contained hardly any blood, and but one small clot.

These five, with the eight previously reported, make thirteen cases which I have myself attended. There were three others which did not come under my immediate observation. Thus sixteen cases, in all, have occurred in persons working in or connected with a hair factory in the vicinity.

The first eight cases I called malignant pustule, which they certainly are; but on further consideration, I rather prefer the term malignant vesicle, as given by Tanner in his "Index of Diseases," inasmuch as a form of disease occasionally occurring upon the face has also received the former appellation, though it has little in common with the present affection.\*

From all accounts it is evident that malignant vesicle owes its origin to a specific poison derived from a disease in certain classes of animals. All evidence goes to show also that the morbid material may be communicated to man by the skins or hair of diseased animals on which the poison has been deposited. This is the only way that the occasional appearance of the disease can be accounted for among hair cleansers and workers, as in the instances we have witnessed and reported. From all I can learn, the disease has rarely appeared in this country. The inoculation of putrescent matter fails to account for its introduction.

The disease is very seldom, if ever, communicated from man to man. I have frequently known of patients sleeping with the healthy, but have never seen a case that could be traced from one person to another.

Malignant vesicle, malignant oedema, and

\* See a valuable paper in the Boston Medical and Surgical Journal, Jan. 7th, 1869, founded on these cases, by R. M. Hodges, M.D., of Boston.

charbon fever, are the three forms in which the disease usually appears. By some, all three are included in the term charbon; by others, charbon and malignant pustule are accounted synonymous.\* Malignant œdema as a separate affection, I have not seen, but cases XII. and XIII. may rightly, perhaps, be classed as charbon fever.

The disease has a period of incubation, eruption, and intoxication. It is not always easy to ascertain the moment of inoculation; but so far as observed, incubation continues from three days to a week.

Malignant vesicle is a virulent tumor, inflammatory and gangrenoid, characterized at the beginning by an appearance on the skin of a non-purulent *serous vesicle*, usually having an areola, and thought by some to resemble the bite of an insect. This vesicle is soon converted into an eschar,

bordered by a ring of little vesicles (as indicated in the accompanying figure), resting on an indolent and more or less hard and elastic base. This base is always indurated, but cannot always be traced, on account of the surrounding œdema, which is most marked near the pustule, and decreases gradually, according to distance from it.

In three to five days, if left to nature, signs of reaction may begin, but more often symptoms of general intoxication appear. After general feverishness, with pain in head and back, there comes on epigastric distress, and vomiting of glairy and bilious matter. The bowels are usually constipated. There is also great anxiety and thirst. Intelligence generally remains but little disturbed to the last. When fatal, the disease usually terminates from the sixth to the ninth day.

\* At the Imperial Academy of Medicine, Paris, session August 11, 1868, M. Davainé communicated the results of his experiments upon animals to verify his theory of the identity of charbon and malignant pustule, which he attributes to the introduction of bacterids into tissues, whence they invade adjoining parts and finally become general.

To introduce bacterids without wounding vessels, he used a small instrument heated by boiling water, with which he touched the skin of guinea-pigs. He thus obtained little vesicles, into which he introduced blood containing bacterids from the spleen of an animal dead of charbon.

At first nothing occurred, but the next day one of the guinea-pigs had a vesicle, which in a few hours became a third of an inch in diameter, with a red areola, and contained serosity full of bacterids.

Another guinea-pig, inoculated in the same manner, presented likewise a vesicle filled with bacterids.

This, he thought, demonstrated the identity of malignant pustule and charbon, by the experimental reproduction of malignant pustule by blood of charbon.—*L'Union Médicale*, Aug. 13th, 1868, p. 233.

Malignant vesicle is to be distinguished from herpes, acne, boil, malignant anthrax, —which is of larger size,\* very painful, and shining red—simple erysipelas, common gangrene, and the bites of insects.

Of late much stress has been laid on the appearance of Bacterids in the serum of the vesicles, and in the blood of the patients.† By some experimenters their existence is considered diagnostic of the disease. They are also thought by some to be its communicating element. They were found in some of the cases under my observation, but the relation they sustain to the affection seems to require still further investigation.

As to treatment little need be added to what was said in regard to previously reported cases.‡ Writers recommend excision, actual cautery thoroughly applied early in the disease, caustic potassa, Vienna paste, corrosive sublimate, especially; fomentations; emetics, purgatives, and bleeding; cooling drinks; tonics and stimulants. In all the cases under my care heroic or debilitating measures were abstained from. In case E. W., one of the severest, a favorable change occurred after the hypodermic injection of a quarter of a grain of sulphate of morphia. This was administered more to relieve the intense suffering from epigastric distress peculiar to the disease, and the vomiting, than with an expectation of prolonging life. It was a point of some interest to me that this case, the severest that has as yet recovered under my care, received no local treatment, as I was desirous to watch its progress unmodified by any disturbing application.

OPIMUM AND STRAMONIUM.—Dr. J. F. Treuman was called to see a mother and two daughters. They had had paroxysms of ague, and had taken, as they supposed, fennel seed, but it proved to have been stramonium-seed instead. When first seen, the mother and daughter were raving like maniacs, while the other was rapidly sinking into coma. Tr. opii was at once given, and morphia injected subcutaneously. The youngest girl recovered rapidly, but the others only after having taken several large doses of morphia. The recovery in each case was complete.—*Chicago Medical Journal*.

# Medical and Surgical Journal.

BOSTON: THURSDAY, FEBRUARY 11, 1869.

IN compliance with our solicitation that he would supply us with a letter on some current topic in physiology, Prof. JOHN C. DALTON, of New York, has sent us the following, which we take great satisfaction in assigning the leading place in this number of the JOURNAL. We have some reason to hope that this is the precursor of a series of occasional letters from some of the most eminent in various walks of the profession; the efforts to obtain which communications will, we presume, be willingly offset against the labor of composition, or compilation, which we shall thus from time to time escape. And we believe no greater service can be rendered to our readers than in providing that they shall be now and then addressed in these pages by teachers and others who are recognized as among the authorities of this period.

NEW YORK, JANUARY, 1869.

MR. EDITOR,—The most interesting event in the physiological circles of this city for the present month, was the reading of a paper on the Cerebellum, before the New York County Medical Society, by Prof. WM. A. HAMMOND. The well-known ability of the author, and his especial devotion to the physiology and pathology of the nervous system, made it an occasion of more than ordinary interest for the members of the Society. The paper was a very elaborate one, and went over the entire history of the two principal theories of the function of the cerebellum which have been in vogue, as physiological doctrines, for the last twenty-five years: Of these, the first and oldest was that of Gall, which regards the cerebellum as the seat of the sexual instinct and of the reflex actions necessary to its activity. Notwithstanding some rather plausible considerations advanced by Gall in support of this doctrine, other facts, drawn both from comparative anatomy and from pathological observations, are so unmistakably opposed to it, that it has been for some years practically abandoned.

VOL. III.—No. 2A

Prof. Hammond presented all these conflicting facts in detail, and showed clearly that the theory of Gall had not been rejected by physiologists without good reason.

He then passed to the history and discussion of the theory of Flourens; viz., that the cerebellum is the seat of a coördinating power for complicated muscular actions. This still remains the debatable ground on which the discussion of the cerebellar functions must be mainly carried on. For however differently the experiments of Flourens may be *interpreted* by various writers, their direct results have never been in the least degree invalidated since he first announced them in 1842. In fact, there is hardly any phenomenon which follows more distinctly or more certainly upon any experiment upon the nervous system, than the irregularity of the voluntary movements always produced by injury or destruction of the cerebellum. Prof. Hammond, however, cited at length the singular facts which have been observed since the discovery of Flourens; viz., that birds which have lost their power of coördination owing to removal of a portion of the cerebellum, may *again recover* this power without the re-production of the missing nervous substance. This has been proved in repeated instances by keeping the subjects of the experiment until nearly or completely recovered, and then killing them and examining the condition of the mutilated parts. It is thus shown that a pigeon, with only one half or one third of his cerebellum remaining, may still be able, at last, to co-ordinate his muscular action sufficiently for all ordinary purposes.

How is this to be accounted for? No doubt it is because the effect of an operation on the cerebellum is not wholly due to the simple loss of its substance, but partly, at least, to the shock or temporary violence inflicted on the cerebellum as a whole. If the animal survives, he may recover from the temporary effects of the shock, and retain only the permanent deficiency due to loss of substance. This deficiency may not be observable in the more simple acts of standing, walking, &c., but in the more extraordinary exertions which

call forth all the combining power of which the nervous centre is capable.

Prof. Hammond, however, believes that the immediate effect of shock upon the cerebellum is the only one which gives rise to the phenomena observed in these experiments. He thinks that injury to the cerebellum produces a state of *vertigo*; and that the subsequent irregularity of the voluntary motions is due to this condition alone. Perhaps the most noticeable point in his paper was the distinction thus drawn between the actual loss of coördinating power and the condition of vertigo, by which it is temporarily disturbed.

No doubt this distinction is a sound one. A man may lose the power of coördinating his muscles, and thus be unable to direct his foot or his hand to a particular spot, although he may know exactly where that spot is. On the other hand, he may lose the power of judging correctly of the distance and direction of an object, and thus be unable to reach it because he is deceived with regard to its position, the power over his muscles remaining unimpaired. This is the condition of vertigo, such as occurs in intoxication, and as a result of some accidental injuries to the head. The question therefore remains, to which of these causes shall we attribute the irregularity of movement observable after injuries of the cerebellum?

In the discussion which followed the reading of Dr. Hammond's paper, it appeared that all were not prepared to decide positively on this point. The definite and uniform results thus far derived from experiments on the cerebellum, and the peculiar and striking character of the phenomena produced by them, have made a very strong impression on the minds of physiologists. They cannot easily avoid the conclusion that in the cerebellum there resides, either a power of coördination proper, or else a nervous endowment which enables the individual to appreciate correctly the distance and direction of neighboring objects; and that one or the other of these faculties is suspended or disturbed by any injury inflicted on this portion of the brain.

After all, the greatest difficulties in the way of a positive doctrine of the cere-

bellar function are those presented by the results of pathological investigation; for it would almost seem as if each successive theory had been met, in its turn, by some case of disease, degeneration or atrophy of the cerebellum, without any marked disturbance of the functions attributed to it. In the estimation of Prof. Hammond, these cases are damaging and even fatal to every received doctrine of the present day. It is always a good thing to have our opinions overhauled from time to time, and summoned anew to the bar of criticism by such a *résumé* as that given in his paper.

J. C. D.

#### COHNHEIM'S ALLEGED DISCOVERY.

In the *Dutch Archives of Medical and Natural Sciences*\* (as we learn through the *British and Foreign Medico-Chirurgical Review*), Dr. Koster treats of Cohnheim's alleged "discovery," by which pus globules outside of the capillaries are made out to be white corpuscles of the blood which have emerged through orifices in the capillary walls. Dr. Koster appears to think this "discovery" to be quite established; and goes on to say, "if we should soon succeed in obtaining a more positive and distinct explanation of the origin of the change of the circulation of the blood, as a starting-point for inflammation, a great light will undoubtedly be shed by the facts discovered in late years upon a process of which we may, in general, assert what Cruveilhier said of phlebitis in particular, '*qu'elle détermine toute la pathologie.*'" That is to say, as Dr. K. seems to suggest, a person is exposed, while heated, to a draught of cold air, and has, within a few days, a pneumonia. Between the chilling process and the inflammation there is a hiatus in science.

We learn, however, through the *Archives de Physiologie, &c.*, of Dr. Brown-Séquard, that Prof. K. Balogh, of Pesth, denies the accuracy of Cohnheim's conclusions relative to the white corpuscles. Repeating the experiments of the latter, Prof. Balogh readily perceived the white globules collect at certain points of the vessels, particularly at the origin of the ramifications; but, in spite of the closest attention, and although

\* Conducted by Donders, Koster and others.

the experiment was often watched for more than twenty-four hours, he never saw a white corpuscle on its way through the walls, or having emerged. He considers the views of Waller, as reproduced by Cohnheim, the result of optical error. He does not positively deny the existence of openings in the walls of the vessels, but is convinced that those openings are only large enough to allow the passage of fluids. He thinks the white globules found in the vicinity of the vessels are produced by the multiplication of cells of connective tissue.

#### THE SUPERINTENDENT OF THE INTERNAL HEALTH DEPARTMENT.

Almost at the last moment before going to press, we are apprised that the election of a Superintendent of Health is soon to be acted upon by our City Government. Were there time to bring the attention of our profession to the matter, we are sure there would be a universal call for the appointment of a medical man, and one of high standing, to the office. It is mortifying to recollect that Boston—which has flattered herself that she was a model city in all municipal arrangements—is behind New York—which we usually look upon as displaying all possible mismanagement in the administration of her affairs—in the regulation of the Internal Health Department. The latter city has done a great work in the past three years through the Metropolitan Board of Health, with Dr. Edward Dalton as Sanitary Superintendent, having a corps of medical officers responsible to him. It is time we protected the lives of our citizens in a similar manner.

When the recent epidemic of cholera was expected, it was feared that New York would be a favorite victim of the devouring pestilence. But, when the cholera came, it found the great metropolis unusually cleanly, and that city was, we believe, among those which suffered least in proportion to size and density of population. The purification of New York was the result of the vigorous and intelligent efforts of Dr. Dalton and his assistants.

Every large town in England, we are informed, is protected by a medical man clothed with large powers by act of Parlia-

ment, for the exercise of which authority he is held responsible.

Our City Physician does not control the Department of Internal Health, and the way in which the conduct of that department has been administered under the late *régime* has been far from satisfactory to some at least who are good judges of what ought to be. Let us hope that heed will be given in time to the recommendation of one at the head of our municipal government, and the health of our citizens placed under the ward of members of a profession which should best know the requirements of public hygiene.

We have received from our friend, Dr. Buckminster Brown, a handsomely bound copy of his paper read at the last meeting of the Massachusetts Medical Society, being a collection of cases in Orthopaedic Surgery. Appended to the letter-press is a series of finely executed plates representing specimens of club-feet and other distortions; also the results of operations. It is a satisfaction to belong to a profession, one branch of which can so convert deformity into symmetry.

"ARGENTO-ALBUMINURIA."—Under this title is described a disease resulting from the medical use of nitrate of silver, observed by Lionville and Vulpian. The kidneys, upon section, appeared as if sprinkled with fine black or bluish dots, which, in fact, are the Malpighian bodies stained by deposited oxyd of silver. The patient (for but one case is mentioned) had taken in all about one hundred grains of the nitrate, during a period of over eight months, five years before her death. The edges of the gums, the choroid plexus, and the supra-renal capsules were also discolored. Most of the tissues of the body may be similarly affected.—*Allg. Wien. Med. Ztg.*, Jan. 5.

Such of our readers as choose to make the experiment, may observe the process of discoloration under the microscope. By adding a weak solution of the nitrate to a group of epithelium cells, their edges may be seen undergoing discoloration.

D. F. L.

COMPRESSION OF THE ABDOMINAL AORTA.—In a case of cicatricial contraction of the vagina, Dr. Nagel employed a modification

of Dieffenbach's plastic operation; dividing the old cicatrix, he transplanted in between its cut edges a portion of skin from the perinaeum. On the fifth day arterial hemorrhage occurred; this was repeated on the eighth, when, other modes of arresting it being impracticable, forcible compression of the aorta by the hands was resorted to, with perfect success.—*Ibid.*

We do not find it stated how long compression was maintained. D. F. L.

**BANTING'S SYSTEM AS A CAUSE OF BRIGHT'S DISEASE.**—Dr. Th. Clemens, of Frankfurt a.M., relates three cases of his own, in which the patients had carried Banting-ism to an excess. So insidious was the invasion of the renal disorder, that when the patients first applied for medical aid the symptoms of Bright's disease, fully developed, were found in each instance. All the cases were fatal, and each was accompanied with a rapid and profound degeneration of the whole system, associated with symptoms referred to the brain and cord.

Dr. C. believes that a tendency to the disease is caused by the loss of the fat of the kidney, together with an excessive supply of albuminous material in the blood.—*Deutsche Klinik*, Jan. 2. D. F. L.

**CASE OF TWINS.**—The mother, in the fourth month of pregnancy, had "a surgical disease of one leg," and at the full term was delivered of twins; one a living, full-grown foetus, the other dead, and of little more than three months' development. The latter was adherent to the placenta of the living child, but had a separate amnios of its own; was not macerated, but "mummified." Its death was ascribed to the disease of the leg.—*Allg. Med. Centr. Ztg.*, Jan. 6. D. F. L.

#### EXTRACTS FROM FOREIGN MEDICAL JOURNALS.

*Professor Owen's Conclusions on the Origin of Species and Nature of Life.*—We showed in a former article that Professor Owen is no votary of the Divinity of Chance. On the contrary, he believes that as every individual animal passes through a succession of forms—embryonic, infantine, adult, and aged—so each group of similar animals descended from common parents, which we call "species," has an innate and preordained tendency to deviate from the parental type, and to produce new forms of a more specialized character. "A purposive

route of development and change, of correlation and interdependence, manifesting intelligent Will, is as determinable in the succession of races as in the development and organization of the individual. Generations do not vary accidentally in any and every direction, but in preordained, definite and correlated courses."

And as with the coming in of new species, so with the extinction of old ones; if the one cannot be believed to be due to fresh acts of miraculous creation, so must the other not be considered due to occasional cataclysm or convulsion, but to the steady operation of law. One cause of extinction recognized by Professor Owen is defeat in the struggle for existence. In 1850 he had shown this, when he said that, in a dry season, the large mammal will suffer from the drought sooner than the small one; if food be scanty, the large one will perish before the small one; if new enemies be introduced, the larger and more conspicuous will be the earlier victims; and smaller animals are, as a rule, more prolific than large ones.

As a test of the theories which account for the origin of species, Professor Owen brings forward the coral. The species of existing *anthozoa* cannot be traced very far back; those with a flexible or with a branched calcareous axis begin only at the tertiary period, and of the genera of eocene lamellate or stony corals all the species are extinct, and have been superseded in their grand and useful operations by those now forming reefs and atolls. As we extend our researches back in time, we find generic and family types of coral polypes passing away; and that the prevalent pattern of stellate cups of rays of *six* or its multiples has superseded a similar pattern of *four* or its multiples.

Now, taking these facts, Professor Owen asks whether a direct act of miraculous creation must be invoked to account for each successive species of coral. Such an idea he dismisses as contrary to the worthy conception of an all-seeing, all provident Omnipotence. It is not, he says, above, but against reason.

Let us, then, assume that the modern are the direct descendants of the ancient corals, and with Professor Owen "test the propounded explanations of their origin by secondary law." That of appetency is untenable, because a coral polype cannot exercise volition. Lamarck's creative machinery can only be applicable to creatures high enough to "want to do something." Is there any difference in the "ambient

medium"? We have no knowledge that the polypes of the Devonshire or Cambrian hills worked in an ocean different from the present, or that, if different, it could change a quadripartite into a sexpartite disposition of the coral cells. The "personifying the fact of such transmutations by the term 'Natural Selection' gives no more insight into the manner of the operations than we learn of that of the budding out of a new leg in a maimed newt by being told that it was done by the "nisus formativus," or by "pangenesiis"!

Professor Owen sums up the contrast between his own theory of "Derivation" and Darwin's theory of "Natural Selection" in few words, which we thus venture to abridge. "Derivation" holds that each species changes in time by virtue of inherent tendencies. "Natural Selection" holds that this is effected by altered external circumstances. "Derivation" sees the purpose of the Creator in the variety and beauty of creation, and the adaptation of each member of it to others, and especially man, a being capable of appreciating beauty. "Natural Selection" feels that if ornament or beauty in itself should be a purpose in creation, it would be absolutely fatal to it as an hypothesis. "Natural Selection" leaves the origin and succession of species to the fortuitous concurrence of outward conditions. "Derivation" recognizes purpose. . .

Professor Owen, dismissing the old doctrines as absurd, and Darwin's pangenesiis as absurd, believes to the full in what has been called "spontaneous generation," or the incessant new development of living beings out of non-living material. He sides with Pouchet and Child against Pasteur. He does not believe in "panspermism," or the doctrine that all the forms of life produced in decaying organic matter come from germs dispersed through the air. He prefers believing that, when the requisite material and conditions are present, other forces are resolved into vital force; and sees "the grandeur of creative power," not in the exceptional miracle of one or few original forms of life, but in the "daily and hourly calling into life many forms by conversion of chemical and physical into vital modes of force." The "CAUSE which has endowed His world with power convertible into magnetic, electric, thermotic, and other forms or modes of force, has also added the conditions of conversion into the vital mode." "Change of force forms part of the constitution of the Kosmos."

We will not follow Professor Owen minutely in the comparison which he draws

between life and magnetism, and between all the actions of living beings, from the attraction of the amœba by a bit of meat to the highest phenomena of consciousness in man; of which his conclusion is that from the magnet which chooses between steel and zinc to the philosopher who chooses between good and evil, the difference is one of degree, not of kind, and that there is no need to assume a special miracle to account for mental phenomena.

Although these ideas must fairly be called materialistic, and openly oppose the notion of an "immaterial indestructible soul," yet nothing can be further from Professor Owen's doctrines than the *low* materialism which sees law without a law-giver, force without an author, and no God apart from matter. It must be remembered in the first place that Professor Owen's ideas of life necessitate the belief in the perpetual presence and working of a personal God, the Lord and Giver of life; that he believes in a future life and resurrection and judgment of the dead, "on the ground of their being parts of a Divine revelation;" and that he shows (and quotes the history of the witch of Endor and of the doubting apostle Thomas to exemplify it) that we really are in no condition to say what is material and what immaterial. We only know of force and its effects, but (as Faraday said) as for what causes these effects we get nothing by defining them as material or immaterial. For our own parts, we must not wander into the ground of dogmatic faith, but, as regards reasonable opinion, we must say that Professor Owen's own doctrines tell quite as much for the existence of an immortal soul as not; that the results of force must be as indestructible as matter, save by the will of God, and soul is one mode of force; and, if the matter be doubtful, we ourselves are not ashamed to be biassed by the spiritual instincts of universal man, and to say, with the Pagan philosopher, "*Si in hoc erro, quod animos hominum immortales esse credam, lubenter erro, nec mihi hunc errorem quo delector dum vivo extorquere volo.*"—*London Med. Times and Gazette.*

#### On Craniotomy and Cæsarcan Section.

By THOMAS RADFORD, M.D.— . . .

Some writers who advocate and sanction craniotomy in cases of extreme pelvic distortion have never performed the operation, nor ever even witnessed a labor which was thus obstructed. Some of them, however, have the candor to acknowledge their want of personal experience. Although it is so positively stated than a mutilated full-grown

infant can be brought through the minimum of pelvic space, can we be assured that this operation can be safely performed? and is there not quite as much danger to the life of the woman as is incurred by the Cæsarean section? I have not the least doubt there is quite as much risk to the life of the mother from craniotomy performed in the higher degrees of pelvic distortion, as there would be from Cæsarean section—both operations being freed from the contingent mischief produced by protracted labor. Writers of great eminence entertain the same opinion.

Can the dimensions of the pelvic apertures be ascertained with such mathematical accuracy as to justify the practitioner in having recourse to craniotomy in the more extreme cases of pelvic distortions? From my own long and extensive practical experience I am firmly convinced that it is impossible to ascertain with precision the exact degree of pelvic contraction in such cases as those in which a very small fractional mistake makes the difference between life and death of the woman. Even in the lighter shades of pelvic distortion it is quite impossible to compute the exact measurements. My opinion is substantiated by our best writers and able practitioners. Practical results also corroborate the above statement.

Many cases are recorded in which the head of the infant has been opened by obstetricians of high rank, but who have afterwards been unable to deliver the woman; the patients have been left to die after the infants had escaped into the abdomen through a laceration in the uterus. I have met with cases of this kind. One is recorded in the London *Obstetrical Transactions*, vol. viii. p. 158. In some other cases abdominal section has been performed in order to extract the mutilated infant. A dogma in obstetrics is sometimes highly dangerous to set forth, especially if practice based upon it leads to the sacrifice of life.

It is stated, if there be a space in the antero-posterior conjugate diameter of  $1\frac{1}{2}$  inch, and a transverse diameter equal to 3 inches, the base of the head of a full-grown infant, face brought first, can be dragged through the pelvis. I deny the truth of this statement, unconditionally put forth as a general rule, regardless of the kind of distortion or the parts of the pelvis involved in the mischief.

I have attempted to introduce Dr. B. Hicks's cephalotribe into a case of the pelvis, but I found it quite impossible to place it within the cavity in its unexpanded state,

much less to open it for the purpose of embracing a head for the purpose of crushing it. . . . . *Ibid.*

Accounts of men with tails have been helping to fill the columns of the daily papers during the Christmas holidays. Many of these stories have taken their origin from monstrosities with spina bifida. To adorn a tale and to be adorned by a tail are two things which differ in frequency. We should like to see a specimen.—*Ibid.*

The *Moniteur* recently contained an account of the discovery by a M. Bertrand of a quantity of fossil human remains in quaternary drift. The remains were discovered in the Boulevard St. Pol, at Clichy, in a sandpit at the depth of seventeen feet, and covered by layers of humus, red sand, five of yellow sand or loess, the latter alternating with four of clay. The last bed of loess rested on the drift. The bones were associated with those of elephant, rhinoceros, hippopotamus, stag, horse, and ox. The skulls found were wedge-shaped and dolichocephalic, the forehead narrow, the cheek-bones very prominent, the occipital foramen very far back, and the meatus auditorius very horizontal.—*Ibid.*

*Apropos* of education, we noticed a sensible letter from Mr. Henry Hayman in the *Times* of Saturday last. Its immediate object is to point out the claims of geology as a branch of natural science the most fitted for the purposes of study in schools. On this he discourses ably and well. But the point to which we would draw attention is his testimony, founded, as he says, on several years' experience in more than one post of chief responsibility, that natural science is no cure for dullness in the pupil, nor has it any special aptitude for bringing out faculties which have lain dormant in other lessons. He gives the palm to studies which are distinctively human in their interest, such as language and mathematics, as the corner-stone of solid education. He maintains that they are fitted in general to invigorate, concentrate, and regulate the forces which lie within the mind itself. We heartily agree with him.—*Ibid.*

*Sanitary Character of Andine Heights.*—Dr. John H. Scrivener, having recently returned from South America, where he practised for many years as a physician in Potosi and other cities in Bolivia, and in the Argentine Republic, has, in a small pamphlet with the above title, recently published, directed the attention of the Profession and of the general public to the re-

markable salubrity of the climate in the mountainous regions of these fine countries, as indicated by the entire absence of pulmonary consumption among the natives, and the great benefit that has been derived by many invalids from the coast and from distant countries when they have resided there for some time.

Dr. Archibald Smith, in his essay on the "Climate of the Swiss Alps and of the Peruvian Andes Compared," remarks that "incipient tubercular phthisis is one of the most common pulmonary affections known in Lima and other parts of the coast of Peru. The disease is almost certainly cured, if taken in time, by removing the patient to the open inland valley of Jauja, which is from ten to eleven thousand feet above the level of the sea." The experience of Dr. Scrivener in respect of the Andine heights of the regions to the south of Peru, and especially of the mountains of Cordova, fully confirm the statements of Dr. Smith. With a marked hereditary tendency to consumption himself, having lost two brothers and two sisters from the malady, he can testify strongly to the good effects of the climate upon himself, independently of what he observed in the case of others.—*Ibid.*

The Paris *Almanach de Médecine* for 1869, the nearest approach to the London Medical Directory (for there is no general Medical Directory for France), furnishes some figures that may be of interest. The Almanack first gives an account of the course of study to be pursued by students, and of the laws regulating the profession. The medical student must, before he makes his inscriptions, have obtained the diplomas of the Baccalaureat-ès-lettres and -ès-sciences, the first costing him 100 and the second 50 fr. For his purely medical studies he has to make sixteen inscriptions during the four years over which these are continued, the entire expense necessary for obtaining his Doctor's diploma being 1272 fr., to which 150 fr. of optional expenses for special advantages may be added. The diploma of the *officier de santé*, or medical practitioner of an inferior class, educated in the provincial schools, and confined in his practice to the department he selects, costs 848 fr. There are in France three Faculties of Medicine. That of Paris, has 6 Honorary Professors, 27 Professors, and 26 *agrégés* or Assistant Professors; the number of doctors admitted from 1798 to 1867 inclusive was 17,190—282 having been admitted in 1867.

The total number of Doctors practising in Paris is 1567, to which are to be added

295 *officiers de santé* and 547 *pharmaciens*. As exhibiting the great difference which prevails in France as to obstetrical practice, as compared with this country, we may observe that the list of licensed midwives given amounts to the formidable number of 764. It is to be recollected, however, that the law compels these women to call in a Doctor of Medicine on the necessity arising of any instrumental interference. . . . . *Ibid.*

At the Annual Congress of German Naturalists and Physicians, in Berlin, Dr. Jürgensen, of Kiel, communicated his observations on the administration of quinine in febrile diseases, saying that this drug had the power of lowering the fever heat, and that this was done by the agency of the nervous system. Dr. Binz, of Bonn, spoke on the antiseptic effects of quinine, and maintained that the drug had no direct effect on the nervous system, but altered the composition of the blood, and that its nervine effects were only secondary.—*Ibid.*

*Treatment of Sea-sickness.*—M. le Coniat, a medical officer of the French Marine attached to the service of the Transatlantic mail packets, states that, after trying the usual remedies, he has since 1865 employed faradisation of the epigastrium in combination with an application of a solution of the sulphate of atropine (two or three centigrammes to 50 grammes), and that this means has proved successful in the great majority of several hundred cases of both sexes in which it has been tried. He thinks that during the first day the vomiting should be allowed to have its free course. He says that he has only met with five cases of abortion during his thirty-eight crossings, and that, in this, opium is just as useful as it is useless in sea-sickness. Women usually, in these voyages, have their menstrual periods hastened forwards by some days, and some even by two or three weeks. Others, again, suffer from genetic excitement, for which the bromide of potassium may be given.—*Ibid.* from *Archives de Méd. Navale*, November.

THERE were 108 deaths in Providence, R. I., during the month of January. Just one third of all the deaths in the month, in the whole city, were in the First Ward, and one third were from scarlatina. After an almost entire absence of mortality from scarlatina for two years, it began to be prevalent early in 1868. The epidemic will undoubtedly spread through the city, growing less severe in warm weather.

## Medical Miscellany.

WE have received from Dr. Toner, of Washington, a notice of the "Dedication of the Hall of the Medical Society of the District of Columbia." We make the following extracts:—

"On Wednesday evening, the new hall of the Medical Society of the District of Columbia was dedicated with appropriate ceremonies. The hall, which has just been completed, is located on the south side of F Street, west of Tenth Street, and is one of the finest in the city. The building is three stories high, with a handsome pressed-brick front. The first story embraces two very fine stores, with large plate-glass windows, and the third story is divided into lodging rooms, connecting only with the adjoining building on Tenth St. But the main feature—that for which the building was put up—is the hall, on the second floor, which fronts 46 feet on F Street, with a width of 36 feet; and adjoining it on the rear are a committee room, 14 by 23, and a library room, 18 by 20 feet. The hall is reached by a commodious stairway and passage, and the entire building is completed with all the improvements modern art could suggest.

"Dr. Wm. P. Johnston was introduced to the audience as the representative of the building committee.

"The objects of the Society in creating this building, he said, were six:—

- "1. The advancement of medical science.
- "2. The cultivation of a taste for medical literature.
- "3. The establishment of more social and fraternal feeling among its members.
- "4. The promotion of that strict morality which our vocation inculcates, and the development of that exemplary and high-toned professional character to which the medical man should ever seek to attain.

"5. The establishment, under the direction of this Society, of a dispensary for the city of Washington.

"6. The accomplishment of the great end for which the medical art is cultivated, which is to secure in the best possible way the interest of the public by raising the standard of medical learning, and by cultivating those graces and ornaments which render the medical man most acceptable and useful in his relations to the public."

Dr. J. M. Toner, the librarian, in course of some extended and instructive remarks, on behalf of public professional libraries, said:—

"Philadelphia has three medical libraries, and the combined number of volumes is about 55,000. The oldest, the Pennsylvania Hospital Library, was founded in 1762, and has now over 30,000 volumes, including pamphlets. The College of Physicians, so richly endowed a few years ago by Dr. Thomas D. Mutter, has nearly 20,000 volumes, including pamphlets, and is the most complete working medical library in our country."

Dr. T. adds, in a private note to us:—"I suspect that we are the first Society without some bequest that has expended so much for its comfort and convenience, and for the benefit of future

generations of physicians. The whole outlay will be about \$40,000."

WE learn from the *Union Médicale* that at the election on Monday, the 4th of January, of a member at large of the Academy of Sciences, in the place of M. Delessert, the friends of M. Ricord were disappointed. It was M. Duméril the younger who obtained the majority of votes.

THE sad announcement comes from Vienna, through the *Union Médicale*, that Professor Skoda is affected with an organic disease which threatens his life.

## MEDICAL DIARY OF THE WEEK.

MONDAY, 9, A.M., Massachusetts General Hospital, Med. Clinic. 9, A.M., City Hospital, Ophthalmic Clinic.

TUESDAY, 9, A.M., City Hospital, Medical Clinic; 10, A.M., Surgical Lecture. 9 to 11, A.M., Boston Dispensary. 10-11, A.M., Massachusetts Eye and Ear Infirmary.

WEDNESDAY, 10 A.M., Massachusetts General Hospital Surgical Visit. 11 A.M., OPERATIONS.

FRIDAY, 9, A.M., City Hospital, Ophthalmic Clinic; 10 A.M., Surgical Visit; 11, A.M., OPERATIONS. 9 to 11 A.M., Boston Dispensary.

SATURDAY, 10, A.M., Massachusetts General Hospital Surgical Visit; 11, A.M., OPERATIONS.

MR. EDITOR,—In the article on Cutaneous Horns of the Eyelid, in this week's issue, omission is made of a case reported to the Pathological Society of London, Oct. 21st, 1862, by Mr. Canton. This horn was removed by him from the upper lid of a woman aged 70. Its dimensions are not stated. HENRY L. SHAW.

ERRATUM.—In our last issue, page 11, line 5th, for "there" read *here*.

### CASE OF MONSTROSITY—(SIREN).

By J. B. S. JACKSON, M.D.

THIS form of monstrosity is characterized by a fusion, and inversion, or turning backward, of the lower extremities, an absence of any distinct parts, externally, of a foot, a fusion of the lower portion of the pelvis, and a great deficiency of the pelvic organs; the head and upper extremities being well formed.

In the present specimen, which was a typical one, the lower extremities tapered almost to a point from the trunk, and in consequence, perhaps, of the inversion were curved gradually forward. At the extremity was a soft and quite movable appendage,  $\frac{3}{4}$  of an inch in length and  $\frac{1}{4}$  of an inch in diameter. This bore some resemblance to a toe, and on dissection three cartilages were found. The leg was about  $1\frac{1}{4}$  inch in length, and the thigh  $3\frac{1}{4}$  inches; the femur being evidently quite broad at each extremity, and showing that there was a fusion of two extremities. At the hip-joint there was considerable motion, but less at the knee. Two patellæ distinctly felt at the back of the joint. No appearance of anus, nor of genital organs. Over the very lower extremity of the spine was a fleshy and somewhat irregular excrescence, about as large as the top of the finger. The lower part of the thorax, upon the left side, was contracted, and in connection with the internal malformations; and, otherwise, the fetus was externally well formed. Its weight was 2 lbs. 15½ oz. Length from vertex to tip of extremity, along the back, and following the curve, 16 inches; and from the vertex to the navel, 8¾ inches.

On dissection, two days after its birth, the following appearances were found:—

Diaphragm wanting upon the left side, but perfect upon the right. A strong muscular band, however, passed in front of the lower part of the œsophagus and towards the left side. The stomach and

spleen were thus allowed to pass up into the left side of the thorax, and the heart was pushed entirely into the right side.

Right lung sufficiently well; but the left consisted of a single lobe, which was smaller than any one upon the other side.

An upper vena cava entered the heart as usual; but upon the left side the great veins formed a separate trunk that opened into the left auricle. The foramen ovale was irregularly developed; there being one large opening toward which the Eustachian valve directed the blood, and a second and rather smaller opening just below it. This last was in a thin membrane, such as is usually seen below the foramen ovale; and the two openings were separated by a muscular band. The two ventricles communicated, and otherwise the heart was well formed. A second vena cava I have met with several times in monstrosities (see this JOURNAL, March 17, 1864), and once I think it must have existed in an adult who was examined at the Massachusetts General Hospital a few years ago. In this last case, a funnel-shaped cavity led off from the auricle toward the left side and back of the heart; and there, being then much reduced in size, it was accidentally cut off.

The rectum terminated in a cul de sac in or very near to the pelvis, was filled with meconium, and gradually dilated towards the last, so as finally to measure about  $1\frac{1}{2}$  inch in diameter. The large intestine was much contracted, and pretty closely connected by a delicate tissue with the under surface of the liver. Otherwise the alimentary canal was normal; the stomach being in no way remarkable, notwithstanding its unusual situation.

The right lobe of the liver was well, but the left was made up of several small and irregular lobes. The gall-bladder was quite small, but the ducts external to it were properly distributed.

Pancreas externally normal.

The spleen consisted of three distinct masses, each about  $\frac{1}{2}$  an inch to  $\frac{3}{4}$  of an inch in diameter, and two others about the size of a pea.

Upon the right side there was a renal capsule, of an oval form, and  $1\frac{1}{2}$  inch in length; but no kidney. This is one of the cases that have been observed several times here, as well as elsewhere, and that show the independence of these organs. Upon the left side the renal capsule was smaller than the other. There was also a kidney that was small for the size of the fœtus, and that contained numerous cysts. I have met with cysts several times in malformed subjects, and am inclined to think that, when we find the organs completely transformed into cysts in adults, and generally without symptoms, the disease may sometimes have been congenital. I have examined one case at least that must have been so; but in this one there were symptoms, and they seemed to indicate the fact of the congenital formation. On incision of the organ, in the present case, there was found no appearance of a pelvis. The ureter, which was small above and large below, was impervious, and extended as far as the uterus.

The uterus, which was in two distinct portions, and far apart, appeared very prominently above the serous surface, as two red, fleshy, ovoid bodies, each about  $\frac{1}{2}$  of an inch in length. Each had its Fallopian tube and ovary perfectly well developed; and the left horn, at least, had its round ligament. Below the serous surface, and intimately connected with each horn, was a distinct, whitish, fleshy, somewhat ovoid body, about  $\frac{1}{2}$  of an inch in length, and that, it was thought, might be the vagina. These last were quite impervious; but both horns of the uterus showed a distinct cavity.

The bladder was wanting.

The aorta gave off two extremely small iliac arteries, and was then continued straight along the median line, across the pelvis and up to the umbilicus; two vessels only being seen upon the cut surface of the cord.

The skeleton of the pelvis and lower extremities having been prepared, the following appearances were seen. The ilia were normal. The ischia were intimately fused throughout—the bodies as well as the rami; and, in consequence of the large development of substance, the ilia were not unusually approximated. The outlet of the pelvis was thus closed by a thick mass of what would have been bone, if possible; though between the ischia and the lower part of the spine there was a space of considerable size that was filled with connect-

ive tissue and fat. The pubic bones were depressed and much elongated, and the symphysis was very prominent and largely developed. The obturator foramina were closely approximated, as in Cruveilhier's case (*Anat. Path.*, liv. 40, pl. 6, fig. 6), and only separated above by a strong fibrous band that ran from the fused ischia to the inside of the symphysis pubis, and below by a little connective tissue and fat. The sacrum was very irregularly developed and turned directly backward. The femur was  $3\frac{1}{4}$  inches in length and quite large; convex posteriorly and flattened anteriorly, with pretty well marked edges, and no appearance of a twist, as in one of Cruveilhier's figures. The great trochanter was very broad, and there were two well-developed heads in distinct cavities, and nearly  $\frac{1}{2}$  of an inch apart. Viewed in relation to the iliac and pubic bones, the heads seemed to be in very proper position. Inferiorly there were two large condyles, which must be regarded as internal condyles, but there was no appearance of an intervening one. Upon the back of the knee-joint were two well-developed patellæ, with their ligaments; and these were inserted into the tibia, which was  $1\frac{1}{4}$  inches in length, and tapered down regularly and suddenly to unite with the three cartilages above mentioned. The breadth of the femur across the two heads was  $1\frac{1}{2}$  inch, and across the condyles  $1\frac{1}{4}$  inch.

The muscles about the thigh were most of them very distinctly made out by their origins and insertions, and were well developed:—the *psaos magnus*, *iliacus internus* and *glutæus maximus*; the *sartorius*, *tensor vaginæ femoris*, three adductors, *rectus vasti*, *semi-tendinosus* and *biceps*. The *glutæus maximus* and *medius*, *gracilis* and *semi-membranosus* were wanting. The adductors were inserted mostly into the line that separated the convex from the flat surface of the femur, and into this last. The recti ran obliquely from the front of the pelvis to the patella. The *vasti externi* were fused, and formed a very powerful mass of muscle upon the back of the femur. Between the sacrum and ischia a considerable quantity of muscular substance was found; but the fibres seemed mostly to run in a transverse direction, and none of the small muscles that run from the pelvis to the great trochanter were made out. Below the knee no muscular fibres were found.

The excrescence over the lower part of the spine was attached to this last by a loose connective tissue, and a considerable

quantity of muscular fibre that arose from the sacrum; but it seemed to have no connection with the spinal membranes.

The case occurred during the month of December, in the practice of Dr. H. P. Hemenway, of Somerville, who very kindly presented the fetus to the Museum of the Massachusetts Medical College. The mother was 24 years of age, of a nervous temperament, and had previously had one well-formed child and one abortion. In the present case, the child was carried to the full period, though its size would not indicate it. The motions had been very feeble, and were described by her as a fluttering sensation. Quantity of liquor amnii exceedingly small, and the labor was otherwise quite natural. The child gasped for about fifteen or twenty minutes; and, meanwhile, the heart was felt beating strongly upon the right side. The cord was short, small, and had an opaque, diseased look. The placenta was thin, and only three or four inches in diameter; and the vessels were small.

Cruveilhier (*Anat. Path.*, liv. xxxiii.) has given an admirable figure of a specimen of this variety of monstrosity, and of the osteology, and also of the osteology of another case in which the fusion was much less complete. Specimens of the kind are to be seen in European cabinets; but I have not heard of a case here, nor have I happened to see a report of one in our medical journals. Perhaps this remark may lead to the publication of other cases that must have occurred. With regard to the frequency of their occurrence, St. Hilaire states in his general history of the Sirens, as they were formerly called, that only about twelve cases are known (*Anomalies de l'Organization*, vol. ii., p. 250); but I think that he must have underrated the number, as I have seen no less than five in the European cabinets, besides a model of a sixth, and other specimens in which the fusion is less complete than in the Siren.

## TWO CASES IN OPHTHALMIC PRACTICE.

By G. HAY, M.D.

I.—*Suppurative Inflammation of the Cornea, with successful result after Iridectomy.*—The operation of iridectomy is a prominent feature of modern ophthalmic practice. Among its many uses it has been found of advantage in certain cases of disease of the cornea. As an instance of this use of the operation the following case is reported:

Oct. 28th, 1867.—Mrs. X., of small stat-

ure, aged 25, with one child some 5 years old. Has had trouble in the left eye for about two weeks. The vision of this eye is much diminished. The cornea is somewhat opaque in the middle. There has been considerable pain in the region of the eye. The pupil being moderately dilated, a continuance of the collyrium previously used was advised on the supposition that it contained a preparation of atropia. The patient was also advised to take some quinine, to use an opiate lotion and to wear plane blue glasses.

Oct. 31st.—For collyrium of 28th inst., substitute sulphate of atropia gr. ss. to water f3i. The pupil dilates well after instillation of this solution.

Nov. 5th.—Has had considerable pain. There is a very slender, light-colored line along the lower edge of the cornea (in the anterior chamber), an appearance which indicates the coming of pus in the anterior chamber. Advised to take some morphine for the pain.

Nov. 12th.—Pus in anterior chamber quite evident, rising to the height of about a line. Pain less. Pupil dilated. Has applied a large blister to back of neck. Discontinue quinine of Oct. 28th.

R. Ferri et quin. cit. ʒi.

Aq. f3iv. M. Dose, f3i.

Nov. 16th.—Pus increased. Eye comparatively easy till to-day. To-day more pain.

Nov. 17th.—Pus movable. With the assistance of Dr. Robert Willard ether was administered. Paracentesis corneæ performed. A small quantity of pus escaped through the puncture.

Nov. 18th.—Had a good night; free from pain. Anterior chamber reestablished. Pupil moderately dilated. Some pus in anterior chamber. Discontinue ferri et quin. cit. Substitute potassii iodid. ʒi. to liquid f3iv. Dose f3i.

Nov. 20th.—No pain of consequence. Eye looks better. The pus appears to be less.

Nov. 22d.—Slept well last night, free from pain. Cornea looks as if containing a deposit of pus. Some circum-corneal injection.

Nov. 25th.—Pus in anterior chamber continues; not as much as before paracentesis. The cornea looks as if burrowed. Discontinue potassii iodid.

R. Liq. ferri iodidi gtt. x. ter die.

Nov. 27th.—Light is disagreeable; eye waters when examined; pus increased in anterior chamber; some pain; vision very poor.

Nov. 28th.—With the assistance of Dr.

B. J. Jeffries ether was administered and iridectomy upwards and inwards performed. After the operation the middle of the cornea over an area of from two to three lines in diameter, presented an appearance of honey-combed purulent infiltration, apparently nearer the inner surface.

Nov. 29th.—Comfortable. •

Dec. 1st.—Some pain—light disagreeable—eye irritable.

Dec. 3d.—Had a good night. No pain. Eye looks better. No movable pus noticed. Infiltration of cornea apparent.

Dec. 6th.—Sight improving. Pus absorbed. Middle of cornea still infiltrated. The eye very sensitive to light. Use the atropine collyrium only every second day.

Dec. 14th.—No pain. Sees more. Eye still sensitive to light. Discontinue atropine and iron. Resume potass. iodid. *R.* Borax gr. ss. to water  $\mathfrak{z}$ i. as collyrium. An ointment containing belladonna to the brow. May walk out.

Dec. 21st.—Better. Borax collyrium only once daily. The ointment only every second evening.

Jan. 3d.—Very much better. Continue treatment.

Jan. 22d.—No pain. Redness gone. The opacity almost gone. Vision pretty good. Health good. Treatment discontinued.

Thus in about three months the inflammatory changes had nearly come to an end, the eye being left in a good condition. It cannot perhaps be *proved* that an equally good result might not have been obtained without the operations. On the other hand, improvement followed upon each operation, though rather slowly for the five days immediately succeeding the iridectomy; and a longer continuance of the disease would very likely have caused permanent opacity of the cornea or serious changes in the iris and lens, or perhaps the morbid processes would even have extended to the deeper parts of the eye. We should therefore consider that the preservation of the eye was due to the interference of art.

II.—*Enucleation of the Eyeball for Intra-ocular Bleeding and Pain following an Iridectomy.*—Mr. J., American, aged 45, farmer, entered the Infirmary July 27th, 1868. *Left eye.* The sight had been failing for six years, with pain at times. For the past two months the pain has been severe, and for the last five weeks has prevented him from working. No cause was assigned for the disease. Patient formerly suffered much from bleeding from the nose, but less during the last few years.

July 27th.—The eye is of normal size; conjunctiva only slightly injected; cornea and aqueous clear; pupil not remarkable. Lens opaque. Iris tremulous. Tension above normal. Sight gone. It was determined to try iridectomy for the relief of the pain. This was done about noon. Shortly after there was severe pain and the bandage became stained with blood. At 4, P.M., on moving the bandage, the flaccid lens in its capsule was found outside of the eyeball, near the palpebral opening, having been forced through the moderate-sized incision of the iridectomy. In the incision was a small clot of blood. The pain and bleeding continuing, it was determined, after consultation, to enucleate. Enucleation was therefore performed; but as the bleeding—instead of ceasing, as is usual—continued rather freely, the cavity was plugged with sponge, and a tight bandage was applied. On the 29th the sponges were taken out; but owing to a return of the bleeding, the cavity was again plugged. The pressure, however, being disagreeable, was on August 1st diminished.

Aug. 3d.—As the tissues of the lids were much swollen, and smelt badly, and the bleeding still continued, the sponges were taken out. Dr. Hodges was requested to see the patient. In accordance with his advice, a single thickness of cotton cloth wet with iced-water was applied. The bleeding then diminished, but a slight oozing continued.

Aug. 4th.—As a clot of the size of a walnut had formed, which projected from between the swollen lids, and a slight trickling continued, Dr. Hodges searched the cavity, under ether, for bleeding vessels, but found none of sufficient size to tie. The surface of the cavity was sponged clean for about half an hour, and then iced water was applied as before. After this the bleeding stopped, the swelling diminished, and the patient rapidly improved.

Aug. 10th.—Discharged convalescent.

The eyeball, examined the day after the enucleation, was found filled with a clot of blood. After removing the most of the clot the choroid was seen almost entirely separated from the sclerotic and pressed together, passing somewhat like a tunnel from the papilla to the anterior part of the eye.

In consideration of the recent pain suffered we were inclined to think that intra-ocular hæmorrhage had been taking place for some time before the operation; but on the other hand it might be supposed that it was a case of separation of the retina with cataract, and that the hæmorrhage was only

a consequence of the operation in an eye predisposed to it by disease. Although the tension of the eye was above normal, the general aspect was not glaucomatous.

### EXTRA-LARYNGEAL OPERATION FOR THE REMOVAL OF GROWTHS UPON THE VOCAL CHORDS.

By E. CUTTER, M.D., Boston.

THE patient, Mr. Albert Litch, of Cambridgeport, was born in 1814; he is a large, well-developed, muscular man, of dark complexion and nervous temperament, and has enjoyed excellent health during most of his life. There has been no cancer in the family, except in the case of a paternal aunt who died at the age of 80. His mother is still living, aged 79; his father was a strong man, and died of ague. He was engaged with Mr. John A. Whipple in introducing photography in the United States, and in 1846 he was injured by overturning a large jar of bromine upon his face and hands, the vapor from which strangled him and almost deprived him of life. Since then he has been actively engaged in mercantile pursuits. He attributes his subsequent laryngeal affection to the inveterate smoking of tobacco, which he used to buy by the barrel for his own use. He "supposes that he has colored more pipes than any man in Boston."

In April, 1864, he was attacked with hoarseness, though he is not aware of having taken cold. There was no venereal taint. His case was submitted to various physicians; one of whom gave him some preparation of squill, saying that the disease might or might not pass away; while another, after two months, dismissed him as among the "opprobria medicorum." Another gave him iodine to inhale, which did no good. Subsequently he went to New Jersey, to try the effect of a change of climate, and two physicians there diagnosed a weakness of the vocal chords. He received no benefit; and on his return home he consulted one of our oldest and best known physicians, who told him "to let doctors of medicine alone."

After this for about a year he did nothing but consult almost every physician with whom he chanced to come in contact. He was completely discouraged, and was, he says, disgusted with the whole medical faculty. Naturally he turned to mediums, clairvoyants, astrologers, and other irregular practitioners, none of whom succeeded in curing him or in making a true diagnosis.

Meantime he had sleepless nights; he lost flesh, strength and energy, and became short of breath upon exertion. He became indifferent to life, and was tempted to suicide. He said that he felt "like a man out in the open sea in a boat, without oars or rudder, expecting every moment to be capsize."

In April, 1867, he was brought to the writer's notice by Dr. John Hart, of this city. A laryngoscopic examination revealed a sessile tumor, occupying the whole of the upper surface and free edges of the left vocal band and a small portion of the right vocal band near the thyroid insertion.

The effect upon his mind of a correct diagnosis was wonderful. The hope of relief made him feel better immediately; and he became able to eat and sleep.

After the diagnosis had been confirmed by repeated examinations, at intervals of days, the patient was told that relief was to be afforded only by mechanical removal; that there were two methods of operating, one from the inside and the other from the outside; while the non-pedunculated character of the new growth and its situation upon the upper and free edge of the band and at the thyroid insertion favored the removal by thyrotomy. Before resorting to the latter process, attempts were made to remove a portion by the month, with little success. Having been assured that by opening the larynx the work of removal could be effected safely, surely, and thoroughly, the patient then entrusted the whole matter to his adviser.

Sept. 26th, 1867, at 2.30 P.M., the extra-laryngeal operation was performed as follows, in the presence of Drs. Louis Elsberg, of New York City, E. A. Perkins, of Boston, Allen, of Cambridgeport, S. W. Abbott, of Woburn, and Mr. Shurtleff, of Boston. The patient was seated in a common old-fashioned wooden armed chair, with a straight back. His chin was shaved and his person in undress. He soon came under the ether, which rendered him violent and pugilistic. When anesthetized he slipped down in his chair, and at Dr. Abbott's suggestion he was secured by a leather strap buckled round his chair. Pulse 80, full and strong. An incision was made with a scalpel in the median line, from the hyoid bone to the third tracheal ring, through the skin, fat and fascia. The hyothyroid membrane, the thyroid cartilage, the thyro-eroid membrane and the cricoid cartilage were denuded. During the dissection there was some embarrassment from the fact that the larynx was in constant motion from con-

tinual efforts to swallow. The denudation measured about two and one half inches in length. The thyroid cartilage was found to be ossified. After the external hæmorrhage had ceased, the lower blade of a bone forceps was entered through the crico-thyroid membrane, exactly in the median line, till it was two-thirds concealed. Simply closing the forceps with force sufficed to sever it cleanly in the middle. The section through the soft tissues was completed with the scissors. The severed parts were held apart by two-tined hooks, one time above and one time below the vocal chord. Fortunately the up and down movements here ceased. The new growth was completely revealed. On the left chord it appeared as a minute lobal excrescence, occupying the whole inner edge like a fringe, and the lower or tracheal surface. On the right vocal chord the growth was similar, but close to the thyroid insertion. It proved to be fragile. The whole growth was removed by the scissors, leaving the surface clean and smooth. The surface of denudation was sponged and carefully examined by each gentleman present, in succession, until all were satisfied as to the completeness of the removal. The site was then cauterized with the acid nitrate of mercury.

As soon as the patient passed into the semi-conscious state of recovery he again became violent. The most remarkable feature of the violence was the completeness of his prostration. He spoke in a loud, coarse, resounding voice, resembling that of a sea-captain in a storm. This phonation lasted for several hours. The return to complete sensibility was retarded by the accumulation of blood and mucus in the mouth, which ran down into the trachea and out of the artificial opening; it was also accompanied by profuse sweating and some flagging of the pulse. The wound was closed by five sutures, through the skin only. The patient was then led to his bed in an adjoining chamber. He was faint and chilly, but his pulse was 80, regular and full. Tr. camphoræ and aqua ammoniæ were given, and hot water was placed at his feet. Vomiting then ensued, a large amount of blood mingled with mucus was evacuated, and the patient assumed a more natural appearance.

The night passed without any serious difficulty. The operator slept in the house, but was not called on to do anything. In the morning the report was that he had slept a few hours, but was hot, and his throat was very sore. The pulse was 80, the skin cool, air occasionally passing

through the opening. Voice alternating between a whisper and hoarseness or gruffness. Morsels of ice were freely used in the mouth. The air was kept moist by evaporating water on a stove, and by hot flatirons thrown into firkins containing water. Mutton broth and milk for diet. Tinct. veratri viridis gtt. xj. once every hour, if feverish.

9.30 P.M.—Pulse 72. Skin warm. Throat sore.

28th, 7 A.M.—Pulse 72. Skin cool. Dysphagia. Rather restless through night. No medicine given. Vaporization continued.

29th, 2.15 P.M.—Pulse 64. Wound united.

30th.—Stitches removed.

Oct. 2d.—Patient went down stairs.

5th.—All plasters removed.

8th.—Phonation coarse and clear; pulse 80.

17th.—Under the laryngoscope everything appeared normal except a slight cedematous protuberance towards the thyroid extremity of the left vocal chord.

Oct. 23d.—Throat feels sore, but the larynx looks very well inside, the vocal chords having their normal pearly sheen. There was some adhesion of the cicatrix to the trachea, which was removed by subcutaneous sections.

At the present time there is an appearance of a return of the disease on the right vocal chord.

## Reports of Medical Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.  
CHARLES D. HOMANS, M.D., SECRETARY.

DEC. 14th.—*Typhus Fever without Eruption.* Dr. BORLAND reported the case.

"The patient, a sail-maker, 37 years old, was brought from a house in Salem Street to the City Hospital, on the afternoon of Dec. 4th. He was in a semi-comatose condition, and the only facts that could be obtained were, that he was in the sixth day of his sickness; that there was no sickness in the house from whence he came, and that his room was very small and badly ventilated. When admitted, he was recorded as speechless; not paralyzed; tongue, very dry and brown, could be protruded a little way, in a straight line; skin dry; pulse 132, small, weak; resp. 32.

"Dec. 5th.—I saw him for the first time,

and found him conscious, but speechless; his face had a peculiar expression of a heavy, dull, passive indifference; eyelids and mouth open; the countenance generally flushed with a dusky reddish-brown hue; the tongue was dry and brown, and there was some sordes on the lips and teeth; the conjunctivæ were, however, not injected. The abdomen was somewhat shrunken, not tender. Skin was generally dry throughout. There was no eruption. The urine was passed involuntarily, but enough was collected for examination. It was dark colored; specific gravity 1018; the chlorides wholly absent; there was no albumen. The physical examination of the backs showed harsh respiration, but of feeble character; no râles. Percussion normal. In the afternoon he had two severe clonic convulsions, affecting chiefly the upper half of the body. His pulse varied from 124 in the morning to 132 in the evening. Temperature  $99.5^{\circ}$  to  $103.5^{\circ}$ . Resp. 32. He was ordered beef-tea and brandy, alternately, every hour, and five grains of carbonate of ammonia in camphor mixture every two hours.

“6th.—The general condition of the patient was much as described, excepting the lowering of all the vital signs. The pulse ranged from 108 to 124, and irregular in its rate. Temperature from  $98.5^{\circ}$  to  $99.5^{\circ}$ . Respiration 24 to 28. Large ecchymoses were seen on each foot. The tongue could not be protruded. Bowels were costive, and were moved by means of enemata, and he was sponged all over with warm alcohol and water.

7th.—The patient appeared slightly better. His tongue was a little sticky, showing a slight degree of moisture. Pulse 132 in the morning, 120 in the evening; temperature  $100.5^{\circ}$  to  $102^{\circ}$ .

8th.—Pulse 120; temperature  $103^{\circ}$  in the morning,  $102.5^{\circ}$  in the evening. Tongue again perfectly dry and brown; the patient could protrude it half an inch. The respiratory murmur in both backs was good. In the afternoon, he had three loose dejections of greenish-brown feces, and at 10 P.M., he began to show indications of failing vitality, and he died at 12 M. on the 9th of December, it being the eleventh day of his disease.

The fact that was most evident, that the man was suffering from the depressing influences of some severe blood-poison, together with the impossibility of finding anything like organic disease to account for his condition, strongly suggested to my mind the fact of the disease being typhus fever. Yet

the comparative rarity of this disease in the community; the absence of the injection of the conjunctivæ, of the peculiar “rotten straw” smell of typhus and of the eruption kept me in a state of uncertainty as to the true diagnosis, until it was verified by the autopsy.

The argument in favor of typhus was in the following facts:

The physiognomy of the patient, presenting, as he did, the nearly true facies typhosa, the injection of the conjunctivæ alone being absent. The pupils were never dilated, although they did not present the pin-hole pupil which Dr. Graves considered as a fatal symptom.

In the dryness of the skin, as is commonly the case after the third day of the disease.

In the absence of sudamina, and the presence of ecchymoses, as recorded on Dec. 6th.

In the temperature, which in typhus, as a rule, does not exceed  $103$  to  $104$ , and after the end of the first week is generally gradually lowered, and in extreme prostration even rates lower than the normal standard.

In the correspondence of the respirations with the law of typhus, not being much heightened till the second week, and in the aphonia, our patient either being speechless or only speaking in monosyllabic whispers.

In the peculiar dry brown tongue, and in the absence of meteorism, or gurgling; with the concave abdomen; and the coming on of diarrhœa of dark greenish brown discharges.

In the dark colored urine of the specific quantity of 1018, with absence of the chlorides.

In the general prostration of the patient, with the tendency to dorsal decubitus, in the occurrence of convulsions preceding death, and in the death itself, occurring on the eleventh day of disease.

The autopsy was made twenty-four hours after death.

The cadaveric rigidity was not remarkable, but there was much livid discoloration of the dependent parts of the integuments. The muscles were everywhere of a very unusually dark color.

Head. There was a marked congestion of the cerebral membranes, and also of the choroid plexuses. The larger vessels were filled with blood, but there was no fine injection. The subarachnoid fluid was largely increased—it had a somewhat opalescent look, but it contained no lymph, and ran off clearly and transparently on raising the confining membrane. The substance of the cerebrum and cerebellum was perfectly

healthy, presenting no trace of inflammatory action.

*Thorax.* The blood was in a very fluid condition, looking when in bulk very dark; when dropped out on a white surface, it looked of a thinner quality than usual. In the left ventricle there was a small, soft, friable white clot. The heart was healthy—paler than usual, and without the staining of its lining membranes which is sometimes seen in typhus. The pleuras showed no trace of recent inflammation. Bronchi, healthy. The lungs were healthy, excepting for the condition of hypostatic congestion. The two lungs were about equally affected. The consolidation was greatest at the posterior part; was of a dark purplish color, extending two or three inches into the substance of the lung, was not bounded by defined margin; had a smooth surface when cut, and on pressure exuded a dark non-aërated serum.

*Abdomen.* The intestinal canal was healthy throughout, with this exception. The lower two feet of the ileum were congested, and throughout the lower six feet of the ileum the Peyer's patches partook of the same congestion, so as to be visible to the eye. They, however, were in no ways thickened, stiffened, elevated, or perceptible to the finger, nor was their mucous membrane in any way softened. The bowel at this part contained a considerable amount of greenish fecal matter. Mesenteric glands healthy. The abdominal viscera were generally in a hyperemic condition, all deeply reddened. The liver was of a normal size. The spleen of double its natural size. The left kidney dark red, much larger than the right, which was of a natural size. There was no other diseased condition detected.

I have considered the autopsy as showing the nature of the disease:—From the absence of inflammation of the brain or its membranes, from the hyperæmia of the cerebral membranes, and increased amount of intra-cranial fluid; from the fluid condition of the blood, the pulmonary hypostasis, and the hyperæmic condition of the abdominal viscera which, had the patient lived a few days longer, would probably have induced softening.

INTERNATIONAL MEDICAL CONGRESS.—Professors Palasciano, of Naples, and Panteleoni, of Rome, have issued proposals for holding an International Medical Congress at Florence in September, 1869. They have laid down the statutes for its management and a programme of the questions to be discussed.—*Med. Times & Gazette.*

## Bibliographical Notices.

*Essentials of the Principles and Practice of Medicine. A Handbook for Students and Practitioners.* By HENRY HARTSHORNE, M.D., Professor of Hygiene in the University of Pennsylvania, &c. &c. Second edition, revised and improved. Philadelphia: Henry C. Lea. 1869. Pp. 452.

THIS work seems to be carefully and conscientiously edited. The hydraulic press, however, applied to reduce a book to one-fourth its proper size, is unfortunately too apt to squeeze it dry of flavor, excepting the flavor characteristic of dictionaries. To read such compends continuously, is to violate the laws of mental hygiene, while a close examination is apt to show that important facts are dropped, and important subjects neglected. For instance, in treating of pneumonia, the author omits to describe the "jacket poultice." In rheumatism, he represents Dr. Davies as using *small* blisters, intended to produce moderate vesication only, applied to the different joints in succession—instead of *large* blisters *simultaneously* applied. In treating croup, he seems to be unaware of the paramount value of a steam-atmosphere, before tracheotomy is performed—although he speaks of the efficacy of the vapor of *lime-water* as a solvent of croup-membrane. He has abandoned tracheotomy in his own practice. The newer additions are valuable and useful.

### OVARIOTOMY—NOTE FROM MR. T. SPENCER WELLS.

WE had set aside the following extract from the *London Medical Times and Gazette* until such time as we should receive from Mr. T. Spencer Wells a reply to a note addressed to him by us. We wrote to that gentleman asking to be informed who was entitled to the honor of having invented the clamp used in his operations. Through the kindness of Mr. Wells, his reply has come promptly to hand; and we now give it, immediately succeeding the extract referred to.

In an article in the London *Medical Times and Gazette*, Mr. Wells, speaking October 28th, 1868, says:—

"Since October last I have completed the operation of ovariectomy in this hospital in thirty-six cases, besides one case in which I performed the operation successfully for the second time on the same patient. Of the thirty-six women, thirty-one recovered and five died; and it is a remarkable fact that in every case in which the pedicle was long enough for me to use the clamp the patient recovered. There were thirty of these cases—thirty clamp cases in one year without a single death."

{ 3 UPPER GROSVENOR STREET,  
London, 25 January, 1869.

DEAR SIR,—The credit of the introduction of the use of the clamp in ovariectomy is certainly due to Mr. Hutchinson, Surgeon to the London Hospital. He first used one in 1858. It was simply the common *calliper* of carpenters which he used and left applied, handles and all. Then the handles were made movable, so that they could be taken off as soon as the clamp was fixed. Then I made the blades parallel, and did without handles. But I afterwards returned towards the original form of clamp, altering the joint and the form of the opposing surfaces of the clamp until I arrived at that which I now use. You may see it figured in Druitt's *Vade Mecum*, ninth edition, 1865, page 541. . . . I have now completed 300 cases. Of the

1st 100 cases 64 recovered and 34 died.

2d 100 " 72 " " 28 "

3d 100 " 77 " " 23 "

85

A general mortality of 28 per cent., but it is very encouraging to note that the mortality has been steadily diminishing with increasing experience.

Yours very truly,

T. SPENCER WELLS.

THE *New York Medical Journal* for January has an article "On the Microscope as an Aid in the Diagnosis and Treatment of Sterility," by J. Marion Sims, M.D., New York. The paper was read at the meeting of the Medical Society of the County of New York, Dec. 7, 1868.

Previously to the discussion of the topic contained in the above caption, Dr. Sims touches upon the question of the incision of the cervix uteri. So far as such incision

VOL. III.—No. 3a

for dysmenorrhœa is concerned, he has "nothing to recant, nothing to undo." But, when it is proposed to do this operation for sterility, without regard to the relief of physical suffering, he has a word of advice for his younger brethren. He looks upon this procedure as "one of great importance, as one of the most valuable in uterine surgery," but thinks we have too blindly followed "the example and teachings of its illustrious author, Sir James Y. Simpson." Speaking for himself, he says: "I am now sure that I have cut open the cervix uteri, perhaps scores of times, when it was both useless and unnecessary; and I know that others have done the same thing." He is confident that almost every surgeon who has performed this operation often has fallen into the same error. He begs, however, not to be misunderstood. It is for sterility that he declares the slitting of the uterine neck to be useless under certain circumstances—as where the husband is sterile. For this frank and manly avowal, we desire to accord to Dr. Sims all credit and honor.

Coming to the main question in his paper—the investigation of the cause of sterility in particular cases—he takes these positions:—1. We must be sure that we have semen with spermatozoa; 2. We must ascertain if the spermatozoa enter the utero-cervical canal; 3. We must determine whether the secretions of the canal are favorable or not to the vitality of the spermatozoa.

Dr. S. claims that with the aid of the microscope, all these questions may be easily settled. He says:—

"When I wish to examine the action of the cervical mucus upon the spermatozoa, I order sexual intercourse in the morning—the dorsal decubitus to be retained for an hour afterward; and I expect a visit from my patient four, or five, or six hours after coition. Sometimes we find spermatozoa in great abundance in the cervical canal, and not one living. (I have occasionally examined the mucus six, eight and ten minutes after coition and found all the spermatozoa dead.) Sometimes we find half of them dead; again, only about a third; again, two thirds."

Thus, then, by microscopical examination of the secretions of the vagina and cer-

vix, he ascertains whether the spermatozoa reach the cervical canal, and whether they are able to live there. If no zoöperms are found, he still knows that the spermatie fluid has entered the vagina and been retained there if he discovers in that cavity "a fluid with the characteristic seminal odor." He has never, but in two instances, "been compelled to resort to Mr. Curling's plan, of getting the man to squeeze a drop of mucus from the urethra, upon a bit of glass, immediately after sexual intercourse." Dr. S. knows many men whose seminal fluid is devoid of spermatozoa, and who therefore cannot become fathers.

"They are all strong, active men, in the prime of life, and all perform the sexual function with vigor. The very fact of their natural vigor and strong passions had been their ruin, for most of them had contracted urethritis during their early and unmarried life, and had suffered from its unlucky sequence, epididymitis. To further illustrate the necessity of the microscope in this department of surgery, I shall append a few cases drawn up as succinctly as possible."

As we once expressed an aversion to some of Dr. Sims's experiments, we think it only just to quote his defence of them, in reply to the animadversions of an English Editor. He says:—

"Now, for myself, I see no indelicacy or impropriety in taking mucus from the vagina and uterus for microscopic examination. It is no more indelicate, no more impure, than to investigate the character and properties of saliva, or bile, or urine, or feces, or pus. And where is the scientific physician, nowadays, who could or would dare to give an opinion on any obscure and complicated disease without some such investigation? To answer that question, I have only to call to the witness-stand such men as Beale, Hughes Bennett, Gull, George Harley, Sir William Jenner, Bence Jones, George Johnson, Stokes, and the immortal names of Addison and Bright; and in my own country, the great names of Alonzo Clark, Austin Flint, John T. Metcalfe, and a host of others. Opposition and ridicule are ever ready, but never yet crushed out a great truth. With the simplicity of my nature, and with the honesty of my purpose, there can be no indecency, and no sacrifice of self-respect in making any necessary physical examination whatever, if it be done with a proper sense of delicacy, and with a dig-

nified, earnest, and conscientious determination to arrive at the truth—a truth without which every step is in the dark, but with which all is as clear as the noontday's sun."

We must say, however, that we have not yet conquered our prejudices in this matter. Nevertheless, we fully recognize the enterprise, tact, and originality which have enabled Dr. Sims to rescue many a patient from a living death, and which have won for him an immense reputation.

*Unilateral Sweating of the Head* is discussed in the *Quarterly Journal of Psychological Medicine* for January, by Roberts Bartholow, M.D., of Cincinnati. The same subject has also been recently brought forward in one of the English journals.

We quote one of Dr. B.'s cases as illustrative of the affection.

"A lady of this city, aged about 40 years, of full habit, inclining to *embonpoint*, consulted me for a peculiar redness of the right side of the face and head, coming on at irregular intervals. She first observes a sensation of warmth in the part; her eye suffuses, and vision becomes dim. Making observation with a thermometer, placed in the right meatus auditorius, at my request, she ascertained that there was an actual rise of 5° F. over the temperature of the opposite side. The redness of the affected skin was quite apparent to those about her. Observing her in one of these attacks I perceived an abundant moisture break out all over the reddened surface, while the corresponding parts on the opposite side were perfectly dry. There did not appear to be any other departure from the healthy state."

Dr. Bartholow says:—

"The cases of unilateral sweating which I have thus observed, and those which I have collected from various sources, may be arranged in four classes:

"Those connected with aneurismal or other tumors in the thorax;

"Those occurring in certain neuroses, as epilepsy, progressive locomotor ataxia, &c.;

"Those connected with a peculiar stomach disorder;

"Those which seem to be independent of any alteration in the function of any organ except the affected skin.

"With regard to the cases belonging to the first class, there can now be no doubt of the correctness—in part at least—of the view entertained by Dr. Gairdner. He at-

tributes the sweating to pressure of the new formation upon the cervical sympathetic or its branches; paralysis of the vaso-motor nerves is thus induced, and an increased supply of blood is thrown into the capillaries of the sudoriparous glands. This explanation is predicated upon the remarkable experiments of Claude Bernard, who demonstrated that division of the cervical sympathetic was followed by unilateral congestion of the vessels on the same side. It is probable, however, that the result in cases of unilateral sweating of the head, connected with tumors in the chest, is not always due to *paralysis* of the fibres of the cervical sympathetic, but to irritation by pressure."

"Mr. Hutchinson has very clearly expressed his views as follows:

"Many clinical facts seem to me to concur in pointing to the sensory nerves as those of most importance in reference to trophic disturbance. At any rate, if it be not the sensory nerve-fibres themselves, it must be some others which travel in close company with them, which are the most important ones. Paralysis of the cervical vaso-motor nerve, although followed by increased supply of blood, is not productive of inflammation. Nor have we any facts in support of the idea that injuries to motor nerves cause inflammation. On the other hand, we find in reference to sensory nerves, the following facts: 1. The crop of vesicles characteristic of herpes zoster is usually mapped out most accurately by the area of distribution of some sensory nerve. 2. That when a sensory nerve, such as the first division of the fifth, is paralyzed, inflammation often follows (of the eye in the case of the fifth). 3. That when certain sensory nerves are irritated (not paralyzed), reflex inflammations often ensue. 4. That after section of mixed nerves, or of the spinal cord, the parts left without sensation often inflame."

"The facts of Dr. Prevost, however, show that irritation of a ganglion of the sympathetic is followed by elevation of temperature and increased secretion of the part to which its filaments are distributed. These experimental facts are quite in harmony with our clinical observations in unilateral sweating of the head. This disorder seems therefore to be produced by an irritation of a ganglion of the sympathetic, and probably has no relation to those trophic disturbances caused by injury of a sensory nerve. I think it is evident, then, that in the fourth class of cases, although no lesion

is discoverable, some disorder exists in one or more of the ganglia of the sympathetic."

The discussion of the merits of *Veratrum Viride* as a therapeutic agent, which has seemed to be somewhat hibernating in this vicinity for some time, has taken its place on the *tapis* abroad. Its power as an arterial sedative is well established; but it is also claimed to be beneficial in pneumonia. Does it always promote the well-being of the patient in that disease? Pneumonia, as we see it now-a-days, if unilateral, usually gets well of itself, when of course the pulse subsides to its usual rate. Does not the accelerated rate of the circulation supply a demand of the system for the aëration of the blood during the period that inflammation shuts off from activity a portion of the respiratory apparatus?

We insert here an account of a case of *Aphasia*\* which occurred in the practice of Dr. Parker, of Melrose. The case was reported at the last meeting of the Suffolk District Medical Society by the Secretary, Dr. John Homans; and obtained from him by the interposition of the assistant editor:

The patient, a clergyman, was about 52 years old at the time of his death. In March, 1867, he had motor paralysis, lasting half an hour, of the left hand and the left side of the mouth and tongue. Occasional numbness of the left hand and the left side of the tongue, during the next few months. He preached through the summer of 1867, but felt miserably. On the 31st of December, 1867, he preached for the last time. He was then unable to recollect quotations; yawned a good deal.

Jan 1st, 1868.—Was suddenly attacked with unconsciousness, which lasted twelve hours; when he recovered, he dragged the right foot in walking. During the next four months he mis-named things. He called a watch "golden vase;" toothpicks, "pick-pockets," &c., but laughed at his own errors, and repeated the right names when told. In June he had another apoplectic seizure; he fell suddenly, but recovered in a few days. During the next six months he improved in general health, and gained flesh and strength.

Jan. 22d, 1869.—Felt uncomfortable; this feeling increased until the 24th. On the forenoon of that day his speech became

\* Vide case of *meningo-cerebritis*, page 11, issue of 4th inst.

thick; at 11, A.M. he became unconscious, with stertorous breathing; convulsions set in, chiefly of the right side, and he died on the 25th, at 4½, P.M.

Autopsy, Jan. 27th, by J. Homans, M.D. The right hemisphere filled the dura mater more completely than the left. The dura mater covering the left frontal convolutions appeared somewhat shrunken, as if the portion of the brain under it were lessened in size. The walls of the arteries of the brain, where not atheromatous, were very thin. The extra-ventricular lobe of the corpus striatum on the left side was divided by the remains of a former apoplectic clot. This spot had a puckered, cicatrized look, was almost linear in shape, and was surrounded by a distinct membrane of a golden-yellow or brownish color. Its cavity was tubular, scarcely half a line in diameter, and irregular in shape; it extended forwards into the cerebral substance half an inch beyond the corpus striatum. Almost no fluid was found in the second ventricle. The septum lucidum was very soft; the right posterior portion of the corpus callosum and of the roof of the right ventricle was quite soft. In the right hemisphere there was a recent clot, purple in color, rather irregular in shape, and about as large as an almond, situated below and behind the corpus striatum, and involving a portion of its cortical substance about one line in thickness. Neither the third frontal convolution of the left anterior lobe, nor the island of Reil, nor the anterior convolution of the middle lobe were diseased. The two effusions occurred in nearly symmetric localities; both were in the extra-ventricular portions of the corpora striata, and both invaded the white substance—on the left side about half an inch anteriorly, on the right about an inch below and behind. The old apoplectic effusion, in the left hemisphere, was *probably* the more extensive. Many red granules, and some blood-crystals, were found in the membrane lining the cavity of the old clot. The arteries seemed to have no aneurismal dilations. The heart was hypertrophied (weight one pound), and was free from valvular disease. The kidneys were granular; the tubuli were crowded with granules. The peculiar affection of speech was only noticed after the attack of January, 1868. It should be added that no symptoms of renal disease were observed during the life of this patient, nor was the urine ever analyzed. The heart's action had been tumultuous, but not irregular.

We make the following extracts from different numbers of the *Union Médicale*:—

In a paper on certain internal symptoms connected with *Locomotor Ataxia*, Dr. Fé-réal gives an illustrative case, promising to report two more similar ones. He lays down as belonging to, and characteristic of the disease, disorders of sensation and of muscular action in the larynx, in the bronchi, in the diaphragm, and in the whole apparatus of the respiratory function.

*Dr. Brown-Séquard on the Seat of Epilepsy.*—At the Académie Impériale de Médecine, Jan. 5th, 1869, Dr. Brown-Séquard communicated the results of some new researches he had made in relation to the effects of lesions of the spinal marrow. He reminded the Academy that twenty years ago he had produced in guinea-pigs epileptic or epileptiform symptoms by cutting through one of the lateral portions of the spinal marrow in the vicinity of the tenth dorsal vertebra. Three weeks or a month subsequently, the animals which had undergone this operation were seized with veritable epileptic "crises." To bring on these attacks, it was sufficient to irritate the skin of the face or neck. Later, the spasms manifested themselves spontaneously, and occurred several times a day.

Dr. Brown-Séquard has recently repeated his experiments with variations. He has ascertained that epilepsy can be artificially produced not only by the section of either half of the spinal marrow in the vicinity of the tenth dorsal vertebra, but also at points higher up, and nearer to the medulla oblongata. He has seen the attacks come on after double section, likewise; and, also, the production of convulsions in the muscles which are supplied with nerves proceeding from the segment of the spinal cord included between the two sections. The new experiments demonstrate, their author claims, that the greater part of the spinal cord has an active share in the production of epileptic convulsions.

At the session of the 12th of January, Dr. Brown-Séquard said that he had collected together, in a book published in 1857, twelve or thirteen cases of diseases or traumatic lesions of the spinal marrow, which diseases or lesions had produced epileptic symptoms. But, he does not infer from

those facts that the spinal marrow was the seat of the epilepsy. He merely believes that the cord, under the influence of certain lesions, becomes the seat of a special modification, in virtue of which there are produced elsewhere organic troubles from which result the epileptic phenomena.

The Professor, in presence of the Academy, experimented on four Guinea-pigs which he had subjected to section of the spinal marrow about two months previously. One of these animals, which had had its spinal cord cut on both sides, went through attacks of convulsions when the two (*les deux*) sides of the face or neck were pinched. Those which had undergone unilateral section merely, had the symptoms only when the skin of the side operated on was irritated. Dr. Brown-Séquard showed besides a female Guinea-pig which had been impregnated a short time after section of the cord. The mamma of the paralyzed side secreted milk more abundantly than that of the well side.

At both sessions of the Academy, when our *savant* set forth his researches upon epilepsy, there was some discussion, on the part of different members, as to whether the convulsions artificially produced in the Guinea-pigs were really epileptic. Relative to the fact observed by Dr. Brown-Séquard of the turgescence of the mamma on the paralyzed side in a female Guinea-pig, M. Gubler stated that he had noticed and reported analogous phenomena as occurring in conjunction with paralysis in the human subject—i.e., hyperæmia of the lachrymal and salivary glands accompanying facial paralysis.

Dr. Brown-Séquard remarked that he had once had a good deal of doubt about the epileptic nature of the symptoms which he had brought out in animals; but after long comparative study, he had arrived at the conviction of the identity of the disease in man with the symptoms produced in his experiments. In reply to objections founded on certain distinctions which Dr. Chaffard had attempted to set up between the two classes of lesions, he declared that "loss of consciousness" was produced in the animals artificially made epileptic; and as to the question of epileptic anæsthesia, he

could pinch the creatures, prick them, burn them during the attack, without determining other phenomena than movements due to reflex action. These latter phenomena have been perfectly well established as occurring in the human epileptic. There exist in epilepsy artificially induced, the three principal characteristics of epilepsy in man—viz., loss of consciousness; convulsive action; and intellectual torpor following the attack.

The attention of the Academy has also been engaged by reports of committees and discussions upon the noxious effects alleged to proceed from the use of *cast-iron stoves*. We are all familiar with the instructions given by Dr. George Derby, of this city, as to the property possessed by carbonic oxide gas (which is so poisonous), of escaping through cast iron, when that metal is just upon the point of becoming red-hot. The asserted production of typhoid fever by this gas escaping from cast-iron stoves was denied by M. Vernois on the basis of statistics. It was also declared by M. Coulier that a rigid analysis showed the dose of carbonic oxide furnished by a cast-iron stove to be really infinitesimal; and, as usually diluted in the air of a room, to be incapable of toxic effects. In the experiments of MM. Henri Deville and Troost it was proved that each *litre* of air contained only sixteen hundredths of a cubic *millimètre* of this gas.

It was said, on the other hand, however, that the calculations of M. Coulier did not settle radically the question of the noxious influence of cast-iron stoves, though they contributed to its solution. And M. Cloquet thought there could be no doubt that that form of heating apparatus was the source of injurious influences.

We append three questions. How large a proportion of carbonic oxide to atmospheric air is necessary to poison to death, at one session (or one *decubitus*) of a certain number of hours? How small a dose of the gas is infinitesimal—i.e., incapable—when daily respired, for many days in succession—of causing malaise, lowered vitality, or impaired health? Will sheet iron transmit the carbonic oxide on the same terms and conditions as cast iron?

Further reports on this important question are forthcoming. Meanwhile we may remark that M. Carret, who is prominent upon that side of the investigation in France, which is maintained with equal prominence by Dr. Derby here, believes he has discovered a new disease originating in the mode of heating above discussed.

Before leaving this subject, we would refer to the remarks—founded on clinical observation—of Dr. Alden, in *JOURNAL* of 6th inst., page 7.

**PERSONAL.**—A former Editor of this *JOURNAL* has the heartfelt sympathies of the profession in his recent bereavement.

The family physician as well as the teacher should read and ponder "An Address delivered before the Massachusetts Teachers' Association, October 17th, 1868," by Dr. H. W. Williams, on Optical Defects in School Children. We had marked extracts which are crowded out.

We have received from Messrs. Leach & Greene one of their "improved steam atomizers." The apparatus is well made, and does its work to our entire satisfaction.

**ICTERUS AND PNEUMONIA.**—Oppolzer, in a clinical lecture, says that in Berlin the coincidence of icterus with pneumonia has been considered to constitute a distinct variety of pneumonia. In his opinion, however, "the whole difference between bilious and non-bilious pneumonia is, that in the former case a certain complication is present. We meet now and then, especially in summer, cases of pneumonia accompanied with severe icterus, a disposition to diarrhœa, delirium and apathy; the abdomen swells, the tongue dries quickly, and the disease assumes a typhoid character. Such cases often occur in large numbers, and it is usual to say that they ought not to be treated by bleeding. But who says that it is an established custom to bleed in pneumonia? Only in Italy, at the present day, is the maxim of ancient physicians still reiterated—'Pneumonia—blood-letting.' We bleed only when the congestion is so great as to threaten, in the lungs, suffocation; in the brain, sopor or paralysis; or when the disease runs a very rapid course, and a large quantity of bloody sputa is thrown up.

We bleed, therefore, not because of the pneumonia, but in spite of it."

He denies that icterus can be caused by suppression of the secretion of bile, or by sanguineous congestion of the liver. He describes two kinds of icterus. In one (hepatogenous), the secreted bile is reabsorbed; this fact is indicated by the brown color of the urine. The other (hæmatogenous), he ascribes to the dissolution of the blood-corpuscles, and the transformation of their hæmatin into hæmatoidin; a substance which Brücke states to be identical with bilifulvin. In this case biliary acids are not found in the urine.

In the majority of cases, when icterus occurs during pneumonia, it is associated with gastro-duodenal catarrh, white stools, and brown urine. If severe, it is a dangerous complication; and the danger increases in proportion to the diminution of the urine, and the accumulation of biliary acids in the blood. Paralysis of the central and of the circulatory nervous systems is the consequence of this state of the blood. Oedema of the lungs comes next in the logical order of phenomena; it is usually preceded by symptoms of prostration, apathy, and delirium; râles are heard in the chest, and death follows with symptoms of oedema and paralysis of the heart. This is the mode of death in all diseases of the liver.—*Allg. Wiener Med. Ztg.*, Jan. 12. D. F. L.

FROM an able and interesting article in the *New York Medical Journal* on the Mechanism of the Crepitant and Subcrepitant Râle, by Austin Flint, M.D., Professor, &c., we make the following extracts:—

"For my knowledge of the artificial production of the crepitant râle in the way I am about to describe, I am indebted to my friend and associate, Dr. Henry F. Walker. Dr. Walker happened to purchase an article labelled 'Patent India-rubber Sponge,' which is designed to take the place of the ordinary sponge for the toilet. The article consists of a block of India-rubber which has been made to assume a cellular arrangement, evidently by the introduction of air or gas while the substance is in a liquid state and during its congelation. On examining the article, it will be seen to be made up of cells of unequal size, the appearance being very like that of a portion of emphysematous lung. The elasticity of the India-rubber causes the article to expand after it has been compressed, the well-known cohesiveness of this substance offer-

ing a certain amount of resistance to the expansion. Now, after having examined the structure, if each one present will compress with the fingers the article which I shall presently ask you to pass around, holding it close to the ear, and then allow it to expand, it will be at once perceived that a crepitant râle is beautifully represented. The fineness and dryness of this râle are perfectly exemplified. It will be observed that the compression of the article causes no sound. This act of compression is to be considered as taking the place of expiration. The expansion is analogous to the movement of the lung in inspiration. The compression brings the walls of the cells into contact, and, from the adhesiveness of the substance, they cohere with a certain amount of force. There being no liquid present, the râle must be produced by the separation of the cell-walls by the elasticity of the substance.

"The production of the crepitant râle, in the manner now illustrated, demonstrates the error of attributing the fineness of the râle to the small size of the cells. The fineness is not less marked when produced by the India-rubber sponge than when it emanates from the pulmonary vesicles and bronchioles. Dr. Carr's mode of illustration, by pressing together and separating the finger and thumb moistened with thick paste or mucilage, also demonstrates this error. . . . The application of the 'India-rubber sponge' to show the mechanism of the subcrepitant râle was suggested by Dr. William J. Chandler, one of the house-physicians at Bellevue Hospital. If a portion of the 'sponge' be compressed and allowed to expand under water, the cells are filled with liquid; and now, holding it close to the ear and alternately pressing it and relaxing the pressure, fine bubbling sounds are produced. That bubbling is caused by the pressure, is shown when the portion of 'sponge,' of the cells filled with liquid, is compressed under water; small bubbles, of unequal size, in great abundance, rise to the surface. This artificial subcrepitant râle is produced alike by the pressure of the 'sponge' and by the expansion after the pressure; thus, the fact of the occurrence of this râle, as a morbid sign, in both inspiration and expiration, is illustrated.

"The bubbling, as thus produced, is very fine, and the resemblance of the subcrepitant to the crepitant râle is admirably shown by producing alternately, with two portions of 'sponge,' one portion dry and the other filled with liquid, the representa-

tions of the two râles. This may be practised with advantage in order to exercise the ear in discriminating the differential characters of these two râles.

"The crepitant râle" being "caused by the separation of the walls of the air-vesicles and bronchioles, in the manner explained by the late Dr. Edson Carr, of Canandaigua, N. Y., in 1842, it is highly probable that the peculiar quality pertaining to the inspiratory sound in the healthy murmur of respiration is due to the same cause, the cohesion of the walls of the air-vesicles and bronchioles not being sufficient to give rise to a crepitant râle."

This suggestion is claimed as original by Dr. Flint.

PNEUMONIA, BLEEDING, RAPID RECOVERY. Under the care of Dr. WILKS.—We are indebted to the *Buffalo Medical and Surgical Journal* for the following extracts from a passage it quotes from *Guy's Hosp. Rep.*

"L. B., aged 18, a servant girl, small but robust, was admitted Sept. 23d, with rational symptoms and physical signs of pneumonia. She got a saline and some Dover's powder. . . . On the following day she was worse, and towards evening was excessively ill; the fever was very high, and there was great oppression of breathing; crepitation was heard all over the remainder of the right lung, and there was some suspicion of the left lung having also been attacked. Mr. Reginald Stocker having informed Dr. Wilks of her condition, the latter ordered her to be bled, and to have calomel, antimony, and opium pill every four hours. This was accordingly done, and with very marked and quick relief to her oppressed breathing. On the following day she was much more comfortable; bronchophony now heard at top of lung; the left quite free. On Sept. 26th the febrile symptoms were subsiding; physical signs of consolidation of lung pretty perfect. On the 28th, much better; fever departing; sputa bronchial; to omit the pills. In a day or two she left her bed, rapidly convalesced, and left the hospital quite well on October 14th.

"As regards bloodletting, Dr. Wilks said he had no data on which he could found an opinion as to its value in pneumonia or other diseases, as an antiphlogistic—that is, as to its power in arresting the inflammatory processes; but he had no doubt as to its good effects in relieving congestion of the lungs under any circumstances. He believed therefore, firmly, that he had seen

venesection save life in pneumonia, bronchitis, heart disease, apoplexy or epilepsy. In pre-auscultatory times it might be that the doctor was apt to style many chest affections pneumonia; but when he was called to a patient sitting up in a chair, livid in the face, panting for breath, and he took out his lancet, and whilst he was bleeding *pleno rivo* he saw tranquillity restored, he could not be mistaken as to the good effects of his remedy. Thus it was in the case above reported; immediate relief was obtained, and it may be, as Mr. Stocker thought, an arrest to the further progress of the inflammation."

WE are indebted to H. Sidney Everett, Esq., for a copy of the First Annual Report of the St. Joseph's Home for Sick and Destitute Servant Girls, No. 45 East Brookline Street, for the year ending Jan. 1, 1869. The President is H. Sidney Everett, Esq.; Vice President, Very Rev. P. F. Lyndon; Treasurer, J. F. Tallon, Esq.; Secretary, John Conlon, Esq. The medical staff is thus composed:—Wm. Read, M.D., Charles G. Putnam, M.D., Consulting. Physicians—Wm. Ingalls, M.D., Hall Curtis, M.D., D. F. Lincoln, M.D., W. F. Munroe, M.D. Surgeons—F. H. Brown, M.D., John Homans, M.D., F. B. Greenough, M.D., S. W. Langmaid, M.D. It is stated that—

"The greater part of our inmates . . . and the class we especially intend to assist, consist of those hard-working servant girls out of place, who have become exhausted and unwell while at their work, and need a temporary respite on such terms that, though far from home and friends, they can find a good home by a moderate payment, or a little light work as equivalent, having a chance during convalescence to seek a new situation, if they do not return to their old one."

ETHER.—Among the *Ephémérides Médicales* it is recorded that the lamented Malgaigne announced to the Academy on the 12th of January, 1847, that having been put in possession of the "American facts" relative to the employment of sulphuric ether for the purpose of blunting sensation, he had tried this agent five times at the *Hôpital Saint-Louis*. A young man of 18 years, with a suppurating phlegmon of the leg, was subjected to the inhalation. At the expiration of ten minutes there was "cataleptic coma." The surgeon made an extensive incision. Two minutes afterwards, the patient awoke. "I am going to operate on you," said Malgaigne. "I am quite willing, since it is necessary," replied the young man. He had felt nothing.

An extirpation of a cervical gland, another operation very similar to that, and an amputation of a leg followed—with entire freedom from pain. One only of the five patients was not rendered insensible by the inhalation.

DR. W. T. THOMAS, in the *Transactions of the New York Medical Society*, suggests how smallpox and scarlet fever may spread, in these words:—

"But the poisons of smallpox and scarlet fever will spread in spite of free ventilation, and they retain their power of causing the same disease for

a long time, and, in the case of scarlet fever, for months. Then the scabs and epidermic scales are doubtless the active agents of propagation. In the one case, the poison may be a mere cloud of molecules; in the other it may be contained in the epithelium and pus-cells, thrown off from the skin in both cases, and from the throat also in one, which adhere to the walls, clothing, or carpets, becoming partially dry; but then, being dislodged by sweeping, dusting, &c., are blown up into the air and inhaled into the lungs of some one, where they again become active by means of warmth and moisture."

CASE OF CO-EXISTENT TÆNIA SOLIUM AND TÆNIA LATA.—F. Hinkle, M.D., of Columbia, Pa. (*The Humboldt Medical Archives*), reports a case of co-existent *tenia solium* and *tenia lata*, which was relieved by an aqueous extract of the bark of the pomegranate root.

### TWO CASES OF PARALYSIS OF INTRINSIC MUSCLES OF THE LARYNX.

Read before the Boston Society for Medical Observation,  
Dec. 21st, 1868, by F. I. KNIGHT, M.D.

I OFFER to the consideration of the Society reports of two cases of paralysis of muscles acting on the vocal chords. The first one, as it now stands, may be open to the criticism to which Mackenzie said some of his were liable, viz., "of wanting in point"; but it is reported, incomplete as it is, on account of the rarity of the affection, and because it illustrates the value of laryngoscopic examination in determining the propriety of surgical interference in cases of dyspnoea.

**CASE I.**—*Paralysis of both Abductors.\**—On the 5th of October last, I was called in consultation by Dr. Winsor, of Winchester, in a case of dyspnoea and stridulous breathing. Arriving, I found a lady, about 60 years of age, sitting up in bed, and breathing with great difficulty. I only learned from Dr. Winsor at this time, that she had had some cough and hoarseness for a year, and had recently become aphonic; and that for some days respiration had been very difficult. I immediately proceeded to make a laryngoscopic examination, expecting to meet with some difficulty on account of the embarrassment of respiration and the nervousness of the patient. Very fortunately, I was enabled to obtain a perfect image of the larynx without touching the mirror to the soft palate.

\* I have in this paper employed the terms adductor and abductor as proposed by Morell Mackenzie; an adductor being a muscle which tends to move the vocal chord towards, and an abductor one which tends to move it away from the median line.

VOL. III.—No. 4

As soon as the image came in view, the cause of the stridulous breathing was apparent, there being total paralysis of both posterior crico-arytenoid muscles, which open the glottis. The vocal chords were, lying near the median line, and did not open at all during inspiration, which was maintained through a very narrow chink about one sixteenth of an inch wide. This space was widened a little during expiration. The chords seemed to be a little oedematous, and on attempted phonation seemed to approximate a little.

Immediate tracheotomy was advised, and of course met with the approval of Dr. Winsor, who also had obtained an excellent view of the larynx. On account of the distress of the patient, I did not ask to be allowed to examine the chest. The operation was delayed till the next day, to obtain the consent of the family, when it was performed by Dr. Winsor, who, at my request, afterwards sent me the following history of the case:—

"Miss B. is 60 years old. Her mother, one sister, and one niece died of phthisis. Perhaps other relatives went the same way. Her mother and one sister, and herself also, were unusually subject to choking at meals—'having things go the wrong way.' Miss B. has for years been rather feeble and subject to cough, but always animated and spirited. About fourteen months ago, I attended her through an illness marked more by debility than anything else—low febrile action and vague pains; abdominal tenderness, but no diarrhoea or rose spots; no epistaxis. For several days there was quite sharp pain in the lower part of left chest laterally, like pleurodynia. There were no auscultatory sounds to correspond, there or elsewhere throughout the chest, though she coughed a good deal. I called this sickness typhoid fever, and am still of the opinion that it was such. She had no cerebral symptoms whatever. She recovered in a lingering way, her appetite and strength being very slow to come back. Insensibly, hoarseness, and want of control over the voice, together with a spasmodic sort of cough, crept on, not grow

[WHOLE No. 2139.]

ing steadily worse, but fluctuating. I attended, off and on, and tried many things for the laryngeal difficulty, giving tonics meanwhile for the general system. No real benefit to the local trouble resulted, but her strength slowly improved.

"Sept. 23d, 1868, I was called to her on account of the old pleurodynia and harassing cough, which latter had now more of a croupy sound. Speech was little more than a hoarse whisper, and sensations of heat, smarting and itching were referred to the larynx; sputa scanty, and she complained that what was started by the cough stopped at the larynx, and 'seemed to fall back.' The cough kept her awake and sitting up in bed a great deal, and so spasmodic and 'strangling' did it become late in September that I was called to her in the night. Physical signs had pointed more of late to tubercular deposit in the lungs, and I apprehended ulceration in the larynx, and asked, Oct. 5th, for the advice of one skilled in the use of the laryngoscope. What the instrument showed, you know.

"I performed tracheotomy Oct. 6th, first etherizing the patient, whose breathing did not grow worse under the influence of the anæsthetic, as I dreaded it would. A previous trial of ether, to relieve dyspnoea, had caused so much distress that I was full of misgiving as to being able to get the benefit of it for the operation. I suspect that the breathing gained more from the suppression of apprehension, than it lost by increased dulling of nervous susceptibility in the already paralyzed muscles. The neck was so long and free from fat, that I hoped to reach the trachea easily, but the hypertrophied condition of the muscles concerned made the operation a tedious one. It was necessary to tie one vein. The tube once in the trachea, cough was provoked by its presence, and great quantities of mucus were thrown out or pulled away. Respiration improved at once, and has maintained its improvement to date (Nov. 18th), six weeks since operation. The patient has gained both quantity and firmness of flesh; her complexion is markedly more ruddy (it was dusky when you saw her), and she eats more, though not as much as is desirable. The cough, however, is no better, and deprives her of quiet sleep. Much tenacious mucus is raised by the tube; only on three or four occasions has any passed the vocal chords."

Dr. Winsor, after stating some difficulties with regard to keeping the tube in place, says:—"If the tube is taken out, she experiences greater ease than usual for

perhaps an hour, but then becomes uneasy, coughs more, and breathes more laboriously. . . . She soon demands the replacement of the tube. The lining membrane of the trachea can be seen to be reddened and thickened.

"At no time has there been any hint of paralysis elsewhere than in the larynx. The mental and perceptive processes are uncommonly prompt, and there is no want of consentancy of muscular action."

It is unnecessary to dwell on the diagnosis in this case; the laryngeal appearances are sufficient; but when we come to the consideration of the causes of the paralysis, the case, as I intimated in the beginning, is somewhat wanting in point. Paralysis is probably due to interference, within the chest, with both pneumogastric or both recurrent nerves. Of the nature of that interference we have no definite information.

The prognosis is of course bad, even now that tracheotomy has been performed, on account of the serious disease implied within the chest.

An immediate operation was necessary, for a very slight inflammation or spasm might have terminated the patient's life before a surgeon could have been obtained.

CASE II.—*Paralysis of the Right Adductors, involving a Question of the Action of the Arytenoideus Muscle.*—W. S. N., a gentleman from Vermont, was transferred to me by Dr. H. I. Bowditch for laryngoscopic examination and treatment, June 7th, 1867. He was a man of large frame, 45 years old, and asked advice on account of loss of voice. He gave the following history. On the 22d of February, 1867, he was taken down with pain, redness and swelling of the joints. He was confined to the house, and most of the time to the bed, for eight weeks. About the third or fourth week of his sickness, he one morning noticed his voice hoarse, and in the afternoon of the same day he lost it altogether. He at this time was having much pain in the right shoulder. Since that time he had continued aphonic. He had occasionally had a little unpleasant feeling about the throat, and said that, when laughing or gaping, he felt as if he

should choke. He had never had any dysphagia. He had had cough occasionally, but never hæmoptysis. He here stated that during the previous December he had epistaxis every day, on two or three occasions profuse, lasting from fifteen to twenty minutes. He had no pain in the chest, no dyspnœa nor palpitation of the heart. He could lie equally well on either side of the chest. He had no symptoms of cerebral trouble. When I first saw him, he was looking rather pale, and showed in his general appearance that he had been sick. He spoke only in a whisper, and was still troubled with pain, particularly in the finger-joints, which were red and swollen. His pulse was 92, of the same character at both wrists. There was no difference in the size of the pupils. Tongue clean. Appetite fair. Bowels regular. Urine high-colored; there had been brick-dust deposit, but there was none at that time. On physical examination, his chest looked large and full, and Dr. Bowditch had found no signs of aneurism or other thoracic disease.

On laryngoscopic examination, I found the right vocal chord immobile in respiration and attempted phonation. It remained in an intermediate position, the vocal process being directed outwards; but the mucous membrane covering the right arytenoid cartilage was pulled towards the median line, and in this way the cartilages of Santorini were approximated. The larynx otherwise appeared healthy. The left vocal chord, on attempted phonation, moved fully up to the median line.

By what could this immobility be caused? By paralysis of the muscles which are necessary for the adduction or abduction of the chord on the right side, or by ankylosis of the crico-arytenoid articulation? But it will be said that all the muscles which adduct the right chord are not paralyzed; for we have evidence of the contraction of the arytenoideus, the mucous membrane and the contained cartilage of Santorini on the right side being pulled towards the median line.

For this reason, allowing to the arytenoid muscle the function generally assigned to it, i. e., of approximating the vocal chords by an approximation of the arytenoid cartilages, I considered and reported the case at the time as one of ankylosis of the crico-arytenoid articulation. "For," I said, "we have evidence of the contraction of this muscle in the approximation of the cartilages of Santorini (which were evidently in this case not united to the arytenoid cartilages), and yet the right

vocal chord does not move at all towards the median line; therefore, there must be trouble in the articulation, preventing motion." Since then I have had serious doubts about the action of the arytenoideus muscle. It has generally been considered an important factor in closing the glottis. It has been thought that it did so by approximating the arytenoid cartilages.

I will quote from a few authorities to show the common belief with regard to this muscle. Most of them speak of closing the posterior part of the glottis, but it will be evident to any one that the cartilaginous glottis cannot be closed without approximation of the anterior angles of the arytenoid cartilages, and consequently movement of the vocal chords nearly up to the median line. In cases of paralysis of the ligamentous glottis, with closure of the cartilaginous, the vocal chords lie quite near each other, but are relaxed, through inefficient action of the tensors (cricothyroids). Sharpey and Quain say:—"The single arytenoid muscle approximates the arytenoid cartilages, and thus constricts the posterior part of the rima glottidis. The tendency of some of its fibres, but especially the superficial and oblique ones, to rotate the arytenoid cartilages outward, and thus, by drawing more apart their anterior processes, to widen the opening of the glottis, is counteracted by the lateral crico-arytenoid muscles." Semcleder says:—"The closure of the glottis is produced by the approximation of the arytenoid cartilages from the contraction of the arytenoideus posticus, and of the superior fibres of the crico-arytenoideus posticus; and by these cartilages being turned inwards towards each other until their internal surfaces touch, from the action of the crico-arytenoideus lateralis." Tobold says:—"Contraction or closure (of the glottis) occurs by means of the true arytenoid muscles, transverse and oblique, both internal surfaces of the arytenoid cartilages being approximated, through innervation from the recurrent laryngeal, and some filaments from the superior laryngeal." Mackenzie says:—"In vocalization, the two chords are approximated or adducted to the median line." "The crico-arytenoidei laterales and the arytenoideus proprius are the adductors."

If the arytenoideus proprius "adducted" the vocal chords, i. e., moved them towards the median line, it would still do so, it seems to me, to a certain extent at least, when the parts supplied by one recurrent laryngeal nerve were paralyzed, as this

muscle is supplied with nervous filaments from both sides. This, however, is not the case. If the left recurrent nerve is compressed by an aneurism of the arch of the aorta, the muscles of the left side of the larynx are paralyzed, and the left vocal chord stands still; and a similar result follows when the recurrent laryngeal nerve on either side is compressed or injured in any way.

Let us consider the anatomy of the parts, and see if there is in their structure any reason for supposing that the arytenoid muscle does not, by itself at least, tend to approximate the vocal chords.

According to Gray, whose account is rather more easily condensed than that of others, the arytenoid cartilages are pyramidal in form, and each presents for examination an anterior, a posterior, and an internal surface, a base and an apex. The internal surfaces of the cartilages lie almost in apposition.

The base of each cartilage presents a concave surface for articulation with the cricoid. It has an anterior, a posterior and an external angle. The external one receives the insertion of the posterior and lateral crico-arytenoid muscles. The anterior one receives the insertion of the true vocal chord.

The ligament connecting the arytenoid and cricoid cartilages is a loose capsular ligament, strengthened behind by a strong posterior crico-arytenoid ligament, which extends from the cricoid to the inner and back part of the base of the arytenoid cartilage.

The arytenoid muscle arises from the posterior surface and *outer border* of one arytenoid cartilage, and is inserted into the corresponding parts of the opposite cartilage. Fournié, in his "*Physiologie de la Voix et de la Parole*," published at Paris in 1866, says simply that this muscle arises from the external border of one cartilage, and is inserted into the external border of the other. Cruveilhier says the same. No one, after considering the origin and insertion of the lateral and posterior crico-arytenoid muscles, will doubt that their actions are respectively to close and to open the glottis. Is there anything in the structure of the parts, which may lead us to doubt the action of the arytenoid muscle in approximating the vocal chords? The arytenoid cartilages lie very near each other naturally, and the vocal chords are not *separated* by an absolute separation of these cartilages, one from another, but by a rotation of their anterior angles outward. The cartilages are so fixed by

their articulations, that, while capable of free *rotary* motion, they are capable of very little *lateral* motion, at their bases; and it is at the base that the vocal chords are inserted, and only an *approximation* of their *bases* would tend to bring together the vocal chords. It would almost seem as if, being attached particularly to the *external borders* of these cartilages, so capable of free rotation, the arytenoid muscles, contracting when the cartilages are already rotated outward, if they moved them at all would tend rather to rotate the anterior angle still further outward. This has been mentioned by Cruveilhier, and Sharpey and Quain speak of such a tendency in certain fibres of the arytenoids. It may be said that in my case the *transverse* fibres of the arytenoid were paralyzed, and not the *oblique*, which run from the base of one cartilage to the apex of the other, and thus are said to approximate the apices. This may have been so; but it seems to my mind more probable that in those cases of unilateral paralysis, where the cartilage of Santorini also stands still, it does so because it is united firmly to the arytenoid cartilage of the same side.

Morell Mackenzie mentions, without comment, the fact that in the only case of unilateral paralysis which he ever examined after death, one of seven years' standing, there was considerable atrophy of the left lateral crico-arytenoid muscle (the left being the paralyzed side), although the arytenoid proprius did not appear to have suffered. It seems probable that this muscle would have shown some change, if it had been inactive for seven years.

If, then, we consider that the arytenoid muscle has very little, if anything, to do with the approximation of the vocal cords, at least till after the rotation has taken place by means of the lateral crico-arytenoid, we must consider its principal action to be what has been assigned to it as a secondary function, viz., to fix the cartilages during vocalization. I will briefly review my reasons for doubting whether the arytenoid muscle plays an important part in approximating the vocal chords.

1. If it did, being supplied with nervous filaments from both the right and the left recurrent laryngeal nerves, it ought still, in case of any lesion of one of these nerves, to approximate the chords, to a certain extent at least, through motor power derived from the other; which does not occur.

In my case there was evidence of the contraction of at least the oblique fibres, the right cartilage of Santorini evidently not being attached to the arytenoid cartilage.

2. The nature of the crico-arytenoid articulation is not such as to permit of much lateral motion in the arytenoid cartilage.

3. The insertion of the muscle itself, being mostly in the external borders of the arytenoid cartilages, is not such as to favor the approximation of the anterior angles (in which the vocal cords are inserted) during contraction of the muscle.

The above case has been reported here merely for the purpose of bringing up a physiological question, and in regard to the further history of it I will merely say, that I applied electricity by means of Mackenzie's original instrument, one pole over the right arytenoid cartilage inside, and the other one outside. Internally I gave iodide of potassium. The patient came to see me nearly every day. On the 22d he spoke in a loud hoarse voice.

On examination the right chord was found as immovable as ever, but the left chord passed the median line and approached the right, so that the current of expelled air caused vibration.

On the 26th he was obliged on account of business to go home. On the 12th of July he wrote me that his voice was the same.

On March 13th, 1868, he visited me again. He stated that after returning home he had himself continued to employ electricity, both poles being of course outside the larynx. The voice gradually improved in quality, and at the time of this visit was as good as ever.

On laryngoscopic examination the right vocal chord was found to move during phonation, but not so much as the left, which still passed the median line. He was advised to continue the use of electricity.

#### LETTER FROM VIENNA.

MR. EDITOR,—You request me to write a "letter to the Boston Med. and Surg. Journal about microscopical matters in Vienna." I have worked but a short time with the microscope, but will endeavor to give you some account of the way that branch is taught here, as far as my experience goes.

The authorities in microscopical matters in Vienna are Prof. Brücke and Prof. Stricker, though there are many other teachers here.

The microscope employed here, I may say, as far as I know, is chiefly Hartnack's, although Nachet's is somewhat used, I believe. But as I myself have used only a Hartnack, my opinion upon microscopes must naturally be extremely one-sided.

There are three sizes of stands in vogue. In the smallest size the stage is stationary. In the two other sizes the stage can be turned round in a horizontal direction, and some are with a joint, so that the stage can be placed at an angle. In the largest size the coarse adjustment is made by means of a screw, while in the other sizes it is made with the hand. The advantages of these stands made by Hartnack, are practicability, simplicity, elegance and cheapness. With these stands any oculars or objectives made by Hartnack can be used. The oculars most generally used are No. 2 and No. 3. I myself use almost entirely a No. 3. For objectives one needs No. 5 and No. 8 for the low powers, a No. 10 immersion for the high power. For all practical purposes these glasses are sufficient. By placing a concave lens in the lower end of the inner, movable tube, the power is very much increased, and in proportion to the strength of the lens used.

The "field" is large, the light good, and the object extremely well defined with these lenses.

Prof. Stricker, with whom I am studying, does not give at first a complex organ to examine, as a cut of lung or skin, &c., but he gives a simple element, such as elastic tissue, epithelium, muscle, &c., to study and follow out in its various forms in the different situations where it is found. When all the simple elements have thus been separately made familiar, then one is competent to examine them in combination, and also (which is of the greatest advantage) one can study by himself and know what he is seeing under the microscope. Every one makes his own specimens, and immediately after the death of the animal. When it is possible the specimen is immediately examined in a wet state. When a thin cut is to be made, the preparation is frozen if possible, or it is immediately thrown into some fluid to harden. Although I can put my microscope at an angle, I look upon that power as only a luxury that can seldom be indulged in, as it is impossible to examine wet specimens or make drawings excepting in the upright position.

In the Laboratory one has not only the opportunity to study with the microscope, but also to learn all methods of "hard injections" by means of which the finest vessels can be followed. By injections of nitrate of silver the epithelium of the vessels is brought into view; and by chloride of gold the nerves are seen in their finest endings.

Embryology can also be studied at the same time, as under the running water of

the faucet are the impregnated eggs of the trout, which are watched every day in their development; while over the gas light are hens' eggs in the process of developing the chick. There is an extremely simple arrangement attached to the gas pipe, by which the flame is regulated so that exactly the proper temperature is kept up night and day for an indefinite length of time.

Physiological experiments are also being made. I placed myself as a student with Prof. Stricker without any fixed aim in view, such as the use of the microscope in the study of the skin in disease, embryology, &c. At present I am studying the effect of drugs on the circulation of animals by means of the sphygmograph; having begun my studies with the Professor upon the blood with the aid of the microscope, and that leading to the observation of the circulation. At the same time I am studying the other tissues of the body.

Last month appeared the first part of a "Handbook of the Study of the Human and Animal Tissues," under the editorship of Prof. Stricker, and contributed to by all the first microscopical authorities of Germany. One part is to appear every three months till completed. As may be supposed, it will be an extremely interesting and valuable work.

H. P. QUINCY.

## Hospital Reports.

### BOSTON CITY HOSPITAL.

THE following case presents two points of great interest. *First*, cancerous disease is excessively rare in the tonsil; *second*, the mode of operating for its removal, by *external incision*, is believed to be without precedent.

CASE I.—*Encephaloid Tumor of Tonsil; Removal by External Dissection.* (Service of Dr. Cheever.)—G. M., a well-formed, robust sailor, aged 34 years, without any hereditary predisposition to disease, and in the enjoyment of perfect health previous to his present disability, presented himself at the hospital with the following history. Six months before, without any known cause, his left tonsil became enlarged and painful. It was treated by his physician as a case of tonsillitis, and, in due time, a portion of it was excised from within. No relief followed, but, instead, the tonsil continued to increase in size, and the region

of the section became an obstinate ulceration. His articulation and deglutition were impaired to a considerable degree, and dyspnoea was quite marked, especially at night.

On his entrance to the hospital the affected tonsil appeared much enlarged. The mass protruded into the fauces, and at its apex presented an indolent ulcerated surface, one inch and a half in diameter, with raised and everted edges. Externally, corresponding with the internal growth, and moving with it as if it were a part, was a nodule lying in the left sub-maxillary digastric triangle, of the size of an English walnut. Manipulation of this mass gave pain. The condition of the man otherwise was excellent. There was neither the history, nor any appearance of syphilis.

He was able to take only liquid diet, and was ordered a gargle of diluted liquor sodæ chlorinatæ, the discharge from the ulcer being offensive.

During an interval of three weeks, it was observed that the tumor doubled in size, internally and externally. The consequent symptoms became much more grave, and called for some operative interference. The situation and large size of the tumor, as well as its projection outside the throat, contraindicated any operation from inside the mouth, and it was therefore decided to attempt removing it from the outside by external incision—a deep and difficult operation, with no precedents to fall back on.

*Operation.*—Etherization was slow and difficult, on account of the obstruction to respiration by the tumor in the fauces. As soon as it was accomplished, an incision was made, extending from just within the angle of the jaw, downward, over the most prominent part of the tumor, a distance of three inches and a half, and in direction parallel with the sterno-mastoid muscle; this incision was met by another, one inch and a half long, extending along the lower border of the jaw. The parts were dissected away on either side until the diseased growth was reached. On enucleation this was found to be an enlarged and diseased lymphatic gland, of the size of an English walnut. It had no distinct connection with the tonsil within, but the disease was distinctly encephaloid in character. It lay outside all important structures, and was entirely removed without difficulty. The dissection was now extended until the tonsil was reached. In its course, the digastric, the stylo-hyoid and the stylo-glossus muscles were divided, the stylo-pharyngeus being left intact, on account of its

proximity to the glosso-pharyngeal nerve. The fibres of the superior constrictor of the pharynx were picked apart with a director, and the pharynx thus opened between them. The finger of the operator was now enabled to sweep entirely around the diseased tonsil, the pillars of the soft palate being left intact; the mass was removed, and presented all the appearances of encephaloid disease, its size being that of a pullet's egg.

The hæmorrhage during the operation was free but not excessive; the largest vessel divided being the facial artery, which was cut close to the carotid. Twelve ligatures were applied. A few of the smaller branches of the facial nerve were divided, and paralysis of the lower lip, on the same side, was the consequence. It was also observed that, on account of the section of the styloglossus muscle, the tongue, when protruded, took a direction toward the opposite side. A single suture closed the horizontal incision; the wound otherwise was left freely open, air passing through it with each expiration. Recovery from these was speedy, and there was no marked depression from the operation.

Not a single complication occurred to hinder the progress of recovery. Suppuration of a satisfactory character commenced on the second day. During the first week after the operation the patient took liquid nourishment, administered by means of the stomach-pump. From the outset there was no pain, and respiration was easy. The granulating process was rapid, and at the end of eight days no fluid passed through the wound in deglutition. After eleven days a small patch was observed at the lower part of the posterior pillar of the palate, which had the appearance of the original malignant growth; it was freely cauterized with nitric acid, and there was no subsequent reappearance. After seventeen days, solid food was swallowed without difficulty. In thirty-one days the wound had entirely closed. The pharynx was entirely clear; and except that the pillars of the palate on the side affected were somewhat separated, it appeared in perfectly normal condition. The tongue was protruded in a straight line, and no paralysis of the lip remained. From the operation until recovery, there was no constitutional disturbance requiring special notice.

As has been already stated, the gross appearance of both tonsil and gland were alike, and unmistakably encephaloid. The following is a record of the microscopic appearance:

"The tumor was of a soft and friable nature, slightly lobulated, and of a grayish-red color. On section it yielded an abundance of juice of a milky color, and of considerable consistency. Under the microscope both the tonsil and the enlarged lymphatic gland appeared the same. They were composed of cells of moderate and uniform size and ovoid form, containing nuclei, and many, also, nucleoli. There was no fibrous tissue between them, but a great number of small dark granules, appearing to be freed nucleoli. On the addition of acetic acid the nuclei became more distinct, and cells were visible containing three or four of them.

"To base the diagnosis of the character of a tumor upon its microscopic appearance alone, is a mistake not to be committed.

"No single element of which a structure is composed can be looked upon as characteristic of the cancerous form of growth only. Neither the character of the cells, nor the nature of the matrix, nor the arrangement of the elementary constituents, can separately determine the point; and it is only by carefully comparing the collective appearances observed upon microscopical examination, that we can decide.

"If we examine the cellular pathology of cancer, we shall find that in the whole range of pathological growths there cannot be found any structure of an absolutely new form, or one which, in one way or another, cannot be regarded as a reproduction of physiological tissues.

"The mere form of cells which compose a structure is of no decisive value; and although it is thought by many that any cell of a spindle or caudate shape with large nuclei is a cancer-cell, yet the fact that on the surfaces of the urinary passages in their whole extent, the same curious bodies, provided with large nuclei and nucleoli, are found, tends to upset the whole theory of there being anything peculiar in a cancer-cell."

#### *Rarity.*

"Cancer of the tonsils is a very rare disease, whether scirrhus or encephaloid. Its existence is even doubted by some authorities, and it is not mentioned by the majority. It has been observed by Lobstein, J. C. Warren, Velpeau (five cases), Vidal de Cassis, Roux and Fano, Lebert and Demarquay. It is observed, for the most part, from the age of forty up to advanced life; and presents itself oftenest in the form of a tumor developed in these glandular bodies, and, at an advanced stage, with the appear-

ance of an open ulcer, showing all the characteristics of cancerous disease.

"Cancer of the tonsils is primary or secondary; sometimes limited to that gland or even to one of its parts (Fano); in other cases sending out irradiations more or less extended towards the neighboring parts, particularly at the side of the velum palati or reappearing in other organs.

"The submaxillary ganglia frequently submit to the law of secondary invasion, which influences the lymphatic glands whose vessels proceed from parts affected with cancer.

"The degeneration is in general encephaloid, rarely scirrhus.

"*Diagnosis*: cancer of the tonsils can be confounded with hypertrophy or with syphilitic changes.

"If at the outset the cancer appears with the aspect of a benign hypertrophy, or if on the other hand the jagged appearance of the tonsil, the ulceration of the orifices of the lacunæ, can in a simple hypertrophy make one think of a cancerous degeneration, there comes a time when the presence of stony hardness, of sanious offensive ulcerations, of signs of cancerous cachexy or the progress of the malady allow its nature to be appreciated.

"The syphilitic changes of the tonsil most often confounded with cancer, are the gummous tumors at different periods of development, and above all at the time of their ulceration. And indeed it is an error with difficulty avoided in the absence of knowledge of the antecedents of the patient, or at least of the proof of a specific treatment.

"Another kind of syphilitic lesion can moreover be a source of error. It is the hypertrophy and the vegetation of plaques muqueuses of the tonsils."—*Nouveau Dictionnaire de Médecine et de Chirurgie pratiques*. Tome deuxième. (*Amygdales—Lésions organiques*.)

In our own case there seemed to be no doubt as to its being cancer. The growth of the tumor, as distinguished from the ulceration and waste of syphilis, was one marked point. The tumor of the tonsil doubled in three weeks. The gross and the microscopic appearances were submitted to several observers, who were of one opinion as to its being cancer. The enlargement of the lymphatic gland and the identity of its structure, under the microscope, with that of the tonsil, were other strong points indicating cancer. The whole aspect of the man was singularly free from syphilitic taint.

*Operative Interference*.—Dr. John C. Warren, in his work on Tumors, mentions two cases of "scirrhus of the tonsil." The first was ligatured by a wire. At the end of five days, after atrocious suffering, symptoms of tetanus appeared, and the ligature was removed. The tumor sloughed away.

The second was seized with hooked forceps, drawn forward and removed with the knife, and the mass in the pharynx was removed with a curved, probe-pointed bistoury. Finally, the actual canterly was applied. The patient recovered.

"Amygdalotomy has been practised frequently in cases of cancer of the tonsil. Velpeau performed this operation upon a man sixty-three years old, who had had a cancer of the tonsil for two years. The cancerous mass covered the velum palati in front, nearly filling up the pharynx; suffocation was imminent. Having laid bare the primitive carotid and passed under it a controlling ligature, Velpeau grasped the tumor with a double hook, drew it forcibly forward, then with a bistoury, the handle of which was fixed and the blade curved, he slit up the left side of the velum palati, and succeeded in extirpating the tumor. At the same time he removed a lymphatic gland affected with cancer, resting upon the pharynx at the lower portion of the parotid region. The patient succumbed seventeen days after the operation from pyæmia. The autopsy showed that all the cancerous element had been removed, and that the large vessels had received no injury. The same operation, but this time without a controlling ligature, was performed by Mason Warren. In a similar case, Demarquay, by means of an incision extending from the anterior border of the sterno-mastoid and terminating at the top of the larynx, laid bare the vessels and nerves which came in contact with the diseased tonsil, and was able to hold them aside, while an assistant managed the *écraseur*, and thus performed the extirpation of the cancerous mass."—*L. A. de Saint Germain*.

There can be little doubt that in this last case the *écraseur* was applied from within the mouth, although the description is obscure.

Removal by external incision is a dangerous operation, on account of the depth of the wound, and the proximity of the internal carotid artery. Numerous and important nerves cross our path, also, as the hypoglossal, the gustatory, glosso-pharyngeal, and the superior laryngeal. Operating from within the mouth we have the danger of swelling and sloughing, and of

hæmorrhage beyond control. By attacking the tonsil from without, we have no inconvenience to fear after the primary dangers of the operation, except the risk of a pharyngeal fistula.

Our cases of œsophagotomy, however, have demonstrated that openings into the gullet close readily. The case above reported closed earlier than the wounds of the œsophagus, partly because the opening was higher up, and partly because the pillars of the palate closed the fistula by a valve-like action of their own.

The facility with which the tonsil can be enucleated with the finger is surprising. The following anatomical peculiarity, however, explains the reason pretty well:

"Perhaps the most important point of the anatomy of the tonsils, next to their proximity to the internal carotid artery, is the fibrous semi-capsule described by Chassaignac, as follows: 'When one has enucleated a well developed tonsil, and examined with attention its external and internal surface, he does not hesitate to declare that the external, or adherent face, is covered with a fibrous semi-capsule, well circumscribed, independent of the neighboring aponeurosis, and resting on the cellular tissue.'"

"The arteries of the tonsil are large compared with the size of the gland; they come from the ascending pharyngeal and the inferior and superior palatine arteries."

We desire, in the report of this interesting case, to express our appreciation of the aid we have received, in the history of the disease and other points, from Mr. F. W. Draper, House-surgeon, and Mr. C. B. Brigham.

#### MASSACHUSETTS CHARITABLE EYE AND EAR INFIRMARY.

Some Cases in the Service of Dr. B. JOY JEFFRIES.

*Congenital Cataract, Double.*—A woman, aged 24, has congenital cataract, nystagmus and convergent strabismus. Vision enough to go about where acquainted. Oct. 30, 1867, iridectomy downwards on right, and, Nov. 12, 1867, same on left, preparatory to extraction. By these, vision not much improved, and in reference to optic nerve atrophy there was a doubt as to extraction; however, five months afterwards, a corneal cut was made with iridectomy-knife in left eye, and with forceps capsule torn away, and cretaceous mass size of four pins' heads from centre of pupil. Patient suffered from abscess on finger, &c., and absorption kept up consid-

erable irritation; yet in two weeks patient fixed with this eye, although there was still some *débris* of lens and capsule. April 13, 1868, patient counts fingers and goes about readily, greatly gratified with improvement of sight. May 14th, 1868, same operation done on right eye. A little vitreous presented, but pupil was cleared. Patient had considerable pain, yielding to morphine. By May 31, 1868, can bear light; pupil quite clear. June 5, 1868, with  $+2\frac{1}{2}$  reads Jäger 14, and with  $+\frac{1}{2}$  tells fingers at 7 feet. Both optic papillæ and fundus oculi now seen. The papillæ are irregular, as also retinal vascular distribution; no apparent disease. Oct. 14, 1868, patient reads Jäger 14 with any glass from  $+\frac{1}{2}$  to  $+\frac{3}{4}$ , and makes out Dyer's X L at 20 feet. The absence of a white cataract filling the pupils, the steadiness of the globes and much improved vision greatly alter the appearance and comfort of this patient. The case is very instructive as to what we may have behind a congenital cataract, and how much even a by no means normal retina and nerve may serve to convey impressions to the brain. The distinction of color was good, the patient having won a new bonnet by selecting it, after operation. A brother and cousin also have congenital cataract.

*Enucleation.*—A domestic, aged 21, has large staphyloma of left eye, at junction of cornea and sclera. Some pain and sympathetic irritation of other eye. Rupture of staphyloma threatening. Patient desires enucleation for cosmetic effect, and also on account of trouble of other eye, "weakness." Oct. 30, 1867, globe enucleated. On section, lens clear; old pannus of cornea; choroid pale, and too readily separable from sclerotic; vitreous clear; staphyloma thin, and bulging irregularly. Vision had long been gone in this eye. Two hours after operation patient had no pain, and wanted food. Patient discharged on fifth day. One month later, patient came wearing false eye, with very perfect deception and considerable movement.

*Cut through Cornea.*—A boy, aged 12, in passing a mill hand, has one third of cornea cut through by end of a piece of wire the workman was pulling from a machine. Scratch on face shows direction of cut. Patient applied to a physician, who said "sight was running out," and applied caustic. Now, Nov. 11, 1867, great pain and ciliary redness. Pupil, irregularly dilated with atropine, showed synechia posterior and traumatic cataract. Leeches, atropine and rest abated symptoms, and

patient was discharged, Nov. 22d, with synecchia posterior and traumatic cataract not then in condition to remove. It seemed almost impossible that the end of a wire could cut open the cornea so cleanly.

*Iridectomy.*—A man, aged 24, pretty well run down from graduation at rebel prisons, has opacity of two thirds of cornea of right eye. Constant pain and some sympathetic irritation; for this iridectomy was done inwards. Iris rotten, and removed all possible. Lens seen opaque and soft. Punctured, and flowed off the consistency of pus, and of sago-like color. This, March 28, 1868; no subsequent pain, and eye "never so quiet." April 1, patient going about, and can see window. April 4, patient discharged. The whole probably sequelae of ulcers of cornea and irido-choroiditis from starvation and exposure in Southern prison stockades.

*Distichiasis Operation.*—A woman, aet. 23, has distichiasis of both upper lids and ulcer of right cornea. Patient in poor condition, but improved by treatment, and ulcer healed. In two weeks, right upper lid "scalped," and two bunches of hair dissected from left upper lid. April 23, 1868, patient discharged, well. These eyes would have finally been destroyed, as many others have, from lack of this simple and very effective operation.

*Cataract.*—A man, aged 79, has double cataract. Some debility, rheumatism in back, troublesome right inguinal hernia. April 14, 1868, left lens extracted by Graefe's method. Lens large and hard; some cortical removed with David's spoon. Discharged, May 5, 1868, with pupil clearing. Sept. 22, 1868, patient returned for glasses.  $V = \frac{1}{3}$  at 20 feet, or 10 feet with  $+\frac{1}{4}$ . Reads Jäger 6 at 7 inches with  $+\frac{1}{4}$ .  $+\frac{1}{2}$  ordered. Success better than anticipated in so old and weak a person.

## Bibliographical Notices.

*A New Operation for Artificial Hip-joint in Bony Ankylosis, illustrated by two Cases.* By LEWIS A. SAYRE, M.D., Surgeon to Bellevue Hospital, Professor of Orthopaedic Surgery, &c. &c. Re-printed, &c. Pamphlet. 8vo. Pp. 39. New York: D. Appleton and Co. 1869.

These cases are re-published from the *New York Medical Journal* for January, 1869, where they are re-printed from the Transactions of the Medical Society of the

State of New York, with Preface and Appendix, says Dr. Sayre, "to vindicate scientific truth, and my own reputation" from "false statements" with regard to them in a "work" recently published.

The vindication is thorough and complete—we need not tarry to rehearse the process—the "slander" henceforth can trouble only its inventor.

As these operations are remarkable, and "the first of their kind," the description, which is not long, is worthy of repetition.

"My object was to go above the trochanter minor so as to retain the insertion of the psoas magnus and the iliacus internus muscles attached to the lower fragment, for the purpose of flexion; and by cutting out a semi-circular piece, thus —, with its convexity downward, and then rounding off the upper end of the lower section to more nearly imitate the natural joint, and give him a fair chance for motion at that point." The plan of the operation may be seen in the figure.

1, head of femur; 2, trochanter major; 3, trochanter minor; 4, line of insertion of capsular ligament (variable); 5, tendon of psoas magnus and iliacus internus muscle; 6, line of transverse section; 7, dotted lines indicating the rounding off of lower fragment after removal of segment.

This operation, designed by Dr. Sayre "for the purpose of establishing a new joint," was first performed on a man at the Bellevue Hospital, June 11th, 1862. The details and history are given with sufficient fulness in the pamphlet. October 12th he "left the institution well, and with very good motion" in the new joint. Late in December he walked to Dr. Sayre's office, and could go up and down the steps without difficulty. April 11th, 1863, the patient wrote from Kentucky "I can now 'rough it' a little without apprehension of having to suffer from it afterward. I can bear my whole weight on the limb without inconvenience, and can walk very well without other assistance than a walking stick." (Page 13.) When last heard of, Jan. 9th, 1869, he was in Idaho, writing to New York for a two-wheeled velocipede!

On the 6th of Nov., 1862, assisted by Profs. Peaslee and Raphael, and in presence of other professional gentlemen, Dr. Sayre performed a similar operation on a Miss L.

This case went on well so far as the operation was concerned. Its subsequent fa-

tality, however, became the source of the "slander," which Dr. Sayre has so triumphantly refuted. In its results, as displayed post mortem, this case is one of the most instructive ever recorded. Not only had a new joint, with synovial membrane, already formed, but it was furnished by an inter-articular ligament, answering in every respect to a new ligamentum teres.

The operation was performed Nov. 6th. On the 8th of Feb. following she got out of bed for the first time. "February 20th she begins to have more control over the movements of her limb by voluntary muscular contraction, and can bear nearly her whole weight upon it. The motions are nearly as perfect as those of the natural limb." p. 22. This patient, while progressing favorably and rapidly, "being able to bear her entire weight on the affected limb, with perfect freedom to passive motion, and gradual increase of control over the voluntary movements" so as to begin to walk around her room, was, early in April, 1863 (misprinted February), suddenly brought down by severe inflammation of the chest, caused by unwarrantable exposure. After a variety of complications and misadventures, the lungs gradually gave way to purulent degeneration and tubercular infiltration. She died May 12th, 1863, from these causes solely, as testified to by a dozen practitioners who attended the autopsy and examined the lungs, and who certify to the published account as "correct in every particular." (Prof. Raphael's letter on p. 37.)

The death of this patient, if it disappointed reasonable expectations from an operation in itself progressing well, brought to light through autopsy, what would never have been credited unseen, "how wonderful" (in the words of Dr. Bush who was present) "and how beautiful was Nature in this reproduction of even the ligamentum teres, in constructing the new hip-joint for the patient, imitating so well the anatomy of the normal articulation." p. 33.

"I made full examination," says Dr. Willard Parker, "of the limb operated upon, and the motion was *free* at the new joint. The parts were then laid open; the new joint consisted of a firm structure surrounding the point of operation, and made a capsular ligament. On opening this capsular ligament, the cavity was found to be lined by a synovial membrane, smooth and lubricated. Between the sawed surfaces of the bone an inter-articular ligament was found." Letter on p. 38.

That there might be no room for any one to think that the drawings were incorrect,

says Dr. Doyle who prepared the specimen for preservation, the specimen was taken while fresh to photographers, and the engravings were made from photographs.

The formation of the inter-articular ligament, which makes this case so interesting, proves to be analogous to the formation of artificial joint in ununited fracture, as happily shown in a case published, in a note at p. 30, in connection with the results of this post-mortem examination.

We commend Dr. Sayre's pamphlet to all interested in such investigations, or in surgical progress. B. E. C.

*Compendium of Percussion and Auscultation, and of the Physical Diagnosis of Diseases affecting the Lungs and Heart.*  
By AUSTIN FLINT, M.D. Fourth Edition.  
New York: William Wood & Co. 1869.

THE Preface says:—"This little compendium was prepared several years ago, by request of a medical friend who intended it for insertion in an annual Physician's Visiting Book. The latter publication was abandoned, and the compendium was published by itself. It has been found convenient in aiding to memorize physical signs, by the private pupils of the writer, and by others, and it has been re-printed in compliance with a demand for this purpose. It is designed, not as a substitute for works treating of auscultation and percussion, but, on the contrary, to promote the study of treatises which consider fully these and the other methods of physical exploration, together with the diagnosis of diseases affecting the respiratory organs and the heart."

The little book fulfils remarkably the purpose expressed in the Preface. We are glad to have it, and heartily recommend it to others.

TRAUMATIC FRACTURES OF THE LARYNX.—The functional symptoms of "Traumatic Fractures of the Larynx" are set down by Mr. William Stokes, of Dublin, as dyspnoea, facial lividity, pain. They are not invariably present.

The physical signs of these injuries are:—

1. Alteration in form of the neck.
2. Increase of volume of the neck.
3. Abnormal mobility of the cartilages.
4. Ecchymosis.
5. Crepitation.
6. Emphysema (rare).—*Dublin Medical Press and Circular.*

## MEDICAL WITNESSES.

*The Medical Testimony at the Trial of Samuel M. Andrews (December 1, 1868, et seq.), for the Murder of Cornelius Holmes, in Kingston, Mass., May 26, 1868.*

A MEDICAL man is called to a person who has been stabbed. The former examines the wounds as to their situation, depth, direction, and number, and as to the blood-vessels which may have been severed. If especially cautious, he notes these points in writing. Summoned into court to testify in the case, he reports what he has seen; and we presume that any opinions he may have formed as to the damage done to, and the risk incurred by his patient, as well as the general condition of the latter, he is bound to state if called upon. The fact of his having formed or not having formed such opinions, the court, we suppose, has as much right to demand from him as any other fact. He is in the position, and receives the fees of an ordinary witness.

But, here is a different case. A murder is supposed to have been committed. Some one is missing from the community in which he has resided. Search is made. Portions are found of a skeleton, which has been in great part destroyed. A piece of the skull is discovered, and is carried to one of our profession, not because he knows anything about the facts in the case, but because he is an eminent comparative anatomist. By means of the knowledge he has acquired by many years of zealous study, he is enabled to give the opinion that the skull from which came the fragment furnished him, corresponds in size and shape with that of the head of the missing person. The result of the investigation and calculation he has made, he testifies to before the jury as an *expert*, and he is entitled to a compensation proportionate to his labor and to the value of his opinion. In this respect, we take it, he stands somewhat on the same footing as the counsel employed in the case.

These illustrations, we believe, set forth

the distinction between the ordinary medical witness and the medical expert. The one simply relates the facts in the case as he may be cognizant of them; the other takes the facts as presented to him, and states his views as founded upon them; provided he accept the position of witness. He is employed by the counsel, on one side or the other; and, in our opinion, may virtually decline to be so employed if he choose. For we believe the expert-witness is usually summoned with his own consent. Or, if subpoenaed against his will, a plea of want of familiarity with the subject on which he is to be interrogated would doubtless secure his dismissal by the presiding judge. And, we take occasion to remark, he *should* thus avoid the witness-stand, unless fully master of the question on which the law in all its dignity pauses to consult him: he should do so on behalf of justice and humanity, of the honor of his profession, and of his own credit: or, he may find to his cost, when too late, that it is the duty of opposing counsel to make the so-called expert show what claims he may have to the responsible position which he assumes to fill. These latter remarks are parenthetical, and have no bearing upon the medical witnesses in the Andrews trial, where all were of high rank in their several departments.

Having directed our attention to the distinctions above alluded to, we are in a position to appreciate the testimony of the medical witnesses in the trial just referred to, as reported in a pamphlet printed at the office of the *True Plymouth Rock* newspaper.

The body of Cornelius Holmes had been found, with marks of violence on it, the 26th of May, 1868. The deceased had made a will in favor of Samuel M. Andrews the prisoner.

Dr. Henry N. Jones—sworn. Have lived in Kingston ten years. Saw Mr. Andrews on the morning of May 27th at my office. He was wringing and twisting himself. I asked him if he had hurt himself. He made no reply. I gave him ammonia, and he recovered. He said Cornelius Holmes had been murdered back of the cemetery. I said to Andrews let us go right down to the cemetery. He declined, saying he must go home and see

his family. He asked me if we had ever said anything about the will, and wished us not to mention it. He said he had told Mr. Newcomb about the will. I rode down to where the body was. Andrews rode with me as far as Stetson's corner. This was not far from seven o'clock in the morning. Edward Gray summoned a Coroner's jury of the persons about there, my name appearing among the others. Mr. Sampson moved the body, which was taken up, put into his express wagon, and carried to Holmes's house. The head was badly mangled, the blood dried upon the face. Some blood was flowing, and it continued to flow after [the body] was put into the wagon. There were a great many stones about, which were bloody—should say fifteen or twenty. The body was taken to Mr. Holmes's room and laid upon a bench for examination. I noticed nothing particular about the clothing. I unbuttoned some of the clothing about the neck. The arms were drawn up and the hands clenched, requiring great force to unclench them. The left fore finger was bruised. No other marks of violence except on the head. The jaws were set, and the tongue protruded through the teeth. The lip was cut through. The right ear bruised, and two wounds about over the ears where the skull was broken through. The wounds were made with some blunt instrument. A little back of the wounds, on what we call the crown of the head, the scalp was badly lacerated. The skull was broken, the brain was protruding, and I took out three pieces of bone, which I replaced when I sewed up the wounds which extended nearly from ear to ear. The wounds were then dressed to make [the corpse] appear as well as we could. The funeral was on Friday.

After the body was disinterred I was present with Dr. Henry J. Bigelow, of Boston, who made an examination. The skull bone was carried away by Dr. Bigelow. I saw Andrews at Holmes's house on Wednesday, 27th. He was before the Coroner's inquest, and said Cornelius had made him a good many presents. He said Holmes came to his garden through the cemetery, and he presumed he went back the same way, but did not notice. I saw Andrews again at his house. He spoke of the will, and said Mr. Newcomb told him to carry the will over to Mr. Damon at the Probate Office. I took out my watch and told him I thought he would have time to go that day. I saw him again at his house, and I gave him a morphine powder at his request. He said he was nervous or excited. Thursday he

came into my office and asked me if I could not give him something to take, he felt badly. I gave him a little whiskey. Before the decease of Cornelius Holmes, Andrews was at my house, and in presence of my family said he expected to be a rich man some time. Cornelius Holmes had made his will and given him lots of property. Said Cornelius came over to Plymouth and Mr. Damon made the will. He requested us not to say anything about it. Was Andrews's family physician. Not at his house often. He was at my house frequently, sometimes professionally and sometimes as a neighbor.

*Cross Examined.*—Andrews called at my house frequently. Sometimes perhaps once or twice a week, but sometimes perhaps not for a month. I had given him morphine before the death of Holmes. Have administered ether to him when he has had his headaches, or trouble about the eye. It was a sort of neuralgic affection. I think I have been called to Mr. Andrews three or four times to administer for this affection in the head. I think I was once called to him for bilious or sick headache. I do not recollect that he ever called at my office for medicine for himself. Was first called to his family in September, 1857. Jan. 16th, 1867, I was called to prescribe for Andrews for illness. Should think Andrews had been troubled with the headache. Think I have seen him with glasses on. Have conversed with my wife in regard to her testimony here yesterday. Heard notes read of my wife's testimony taken by Ellis Ames, Esq. This was at the house of Alexander Holmes last evening. The interview with Mr. Andrews with regard to the will was at my house, and in the evening. Have heard Andrews say, since Holmes left his house, that he had some of Holmes's silver ware to keep. When I first saw Holmes's body it was lying by the cart rut. Should think the soil might be a few inches above the top of the head. Saw several stones lying near the body. One stone near the head in the ground had a blunt edge, similar to [that of] a cold chisel. The stones extended both ways from the body some two or three rods. Saw Geo. F. Willis about the body, at the time it was found; think he took some things from the pockets. He was one of the jury. The skull was broken in upon both sides, and more particularly upon the back of the head. I prescribed ether for Andrews the morning after the murder, because I thought that this was most likely to make him feel better. Should say Andrews was *rather* a nervous man, not specially so. His reputation as a good citi-

zen, for humanity, and kind heartedness, was good generally.

*To Mr. Somerby:*—Should think there might have been five or six loose pieces of the skull.

*Re-examined by the Attorney General:*—Was at the house of Mr. Alexander Holmes last evening and heard Mr. Ames reading his notes to Mr. Holmes. Heard him reading my wife's testimony, and was interested to hear what it was.

Though the statements of Dr. Jones were valuable as those of a medical man, he simply related the facts of which he was cognizant in the case, having been subpoenaed as an ordinary witness.

We now turn to the testimony of the medical experts.

Dr. Henry J. Bigelow—sworn. Have been professor of surgery in Mass. Gen. Hospital 21 years. Saw the body of Cornelius Holmes in the Town Hall, Kingston. I had with me Dr. LeBaron Russell and Dr. Porter of Boston, and Dr. Jones of Kingston. The body was in a good state for examination, the wounds principally on the back of the head, on the left side. A short distance above the right ear, there was a detached wound. The upper lip was cut through. The scalp was very much torn, the head bloody, the wounds vertical and parallel, in the line of the neck up and down the body. You could pass your hand under the scalp and feel loose bones, some of them driven into the brain. Counted eleven detached pieces of the skull. Blood was found all over the surface of the membranes of the brain. The membranes of the brain were torn, and the brain largely torn underneath. There were slight wounds on both hands, and black and blue spots on the left shoulder and face. The internal organs were healthy. The top of the skull of Holmes was here exhibited by the witness, and the nature of the wounds fully explained. (The skull was shown to the jury, and the detached pieces of bone shown, most of them being now attached by wire.) At the time of the examination there was one piece missing,\* which is here identified. The wounds were by some blunt instrument. They may have been made with stones. The state of the skull indicated repeated blows. The blows, judging from the appearance of the skull, could not have been made from below upwards, but must have been made

when the skull was below the party striking. This was indicated by the parallel and longitudinal wounds on the back of the scalp. Blows inflicting such injuries as were indicated by the wounds on the side of the head would *stun* a man more or less, but might not deprive him wholly of his consciousness. A man found in the position in which Holmes was found must have been alive when he first came into that position. Found no wounds of consequence excepting upon the head. Anything like a pool of blood must have come from the head. Examined the brain of Holmes, which was perfectly healthy. The blood between the scalp and skull came from wounds inflicted on the head. A man might be able to cry out after the stunning blows on the side of the head. Such blows would reduce a man's strength, and might knock him senseless.

*To the Court:*—Should think the penetration of those pieces of the skull, must have produced death in a short time. He may have lived an hour or two.

*Cross Examined by Mr. Davis:*—The left thumb was injured, the tendon being cut. The side wounds were an inch or more above the ear. The notes which I dictated were taken by Dr. LeBaron Russell. There was on each side of the head a separate wound, indicating these wounds to have been inflicted from different directions. The principal side wound of the scalp was a star-shaped one, and made by a direct blow. The wounds on the side of the head might have been made, and still a man be sufficiently sensible to cry out. He would not necessarily have been insensible. Should say half a teacup full of brain may have been gone, perhaps less. Think it not unlikely the cut in the brow came from some hard substance on the ground under the head. A heavy blow upon the head might produce copious nosebleed.

*To Mr. Somerby:*—I mean to assert that such blows could not have been made from below upwards, in my judgment. The muscles of the arm are not strong enough to accomplish such a result, i.e., to comminute so greatly the back of the skull of a tall man while struggling, nor would the blows have been so symmetrical as the parallel slits in the scalp indicate. This is my opinion. Cannot tell exactly how many blows were necessary to produce such wounds as were found on this skull.

S. Dana Hayes—sworn. Am consulting and analytical chemist and State Assayer. On the 30th of May I received a vest from

\* This fragment had been recently picked up at the place where the body was found.—Ed.

officer Pratt, purporting to be the vest of one Mr. Andrews of Kingston. [Identifies the vest.] I retained this vest for several days, and early in June Dr. White and myself examined it; we cut it, Dr. White taking part, and the remainder I retained. One piece had a clot of blood upon it. Dr. White and myself divided this piece equally; compared it with blood said to be that of the murdered man, and found it exactly similar; compared it with sheep, chicken, and oxen's blood, and found it entirely different. Other clothing was brought to me, which I here identify by marks made upon it; found blood upon pieces of the coat and pantaloons. Identifies the fence rail, before sworn to by Macoy; found upon this, blood precisely the same as found upon the vest. Identifies a pair of shoes and a gray hair taken from one of the shoes.

Dr. J. C. White—sworn. [A good deal of Dr. White's testimony was too scientific to be reported. The remainder, we are authorized to say, was to the effect that blood-stains, grey hairs, and pine-needles were found in the breast pocket of the deceased. Two of these stains had not penetrated through the cloth, &c. &c.—*Ed.*]

Dr. Hayes re-called.\*

*Cross Examination*:—The examination of the rail was made entirely by the microscope, and was not subjected to chemical analysis.

Thus far the medical testimony is beyond cavil. We deem it well worth reading for the clear picture it gives of the things described. And, it suggests to us in passing an incidental question. It tells us that the head of the deceased was battered by blows, which must have been, in part at least, from above downward; as when the victim lay prostrate, perhaps. Some of these blows may have been dealt with the bloody stones found in the vicinity. But, that which felled him—from whatever direction it may have been struck? On the theory of premeditated murder, did the assassin trust to the stone with the "blunt edge" to strike his victim prostrate, or

was some other instrument used, such, for instance, as a slung-shot or a hatchet?

Subsequently to the foregoing, the statement of the prisoner is put into the case. He confesses taking the life of Holmes, but claims that it was in self-defence while resisting a *felonious assault* on the part of the deceased. It would appear that, lest he should be convicted of murder or manslaughter, on the ground that he used more violence than was necessary for self-defence, his counsel attempted to set up the theory that he acted under the influence of a paroxysm of insanity. Here, then, is brought in the testimony, as experts, of gentlemen prominent before the community in dealing with problems of mental unsoundness. In these intricate questions there is doubtless much room for differences of opinion. At all events, we find Dr. Jarvis and Dr. Choate opposed to each other on the witness-stand.

Dr. Edward Jarvis—sworn. Reside in Dorchester. Am a physician. Have practised 39 years. Have had private patients with me for many years in reference to their being insane. Insanity of ancestors leaves the posterity more likely to be insane. If insanity extends through several generations it is more likely to be transmitted to posterity. People sometimes become insane suddenly. The number as compared with the whole number that becomes insane, is few. There are many records of cases of sudden insanity which are often brief, and the mind soon returns to its sane condition. At the time the moral sentiment seems to be obliterated. A homicidal mania is supposed to be more likely in persons whose ancestors were insane.

[A long discussion occurred relative to the testimony of this witness in regard to hypothetical questions, and much of the testimony was (concerning—*Ed.*) opinions which have been read in books, and could have little weight with the jury.]

[Recess for ten minutes. On the re-assembling of the Court, and suggestions in regard to the testimony, the examination of Dr. Jarvis was resumed.]

Have heard the evidence in this case and it tends to the suspicion of insanity. Visited the prisoner Thursday, when he made an exclamation and his pulse was 132. It indicated great anxiety.

*Cross Examined*:—Do not think the prisoner at the bar is insane to-day. The doc-

\*The report of Dr. Hayes's testimony is so brief and lucid that we did not request to have it verified. The practical result of Dr. White's investigation, we by his authority state in the text. The other *experts* have most kindly corrected the accounts here given of their statements in the witness-box, so far as errors (and there were *flagrant ones*) are concerned. As they now stand, nevertheless, we are apprised that these reports are not complete; but, we think they may suffice to give an adequate idea of the leading facts and opinions in the case.

trine of transitory mania is held by many physicians. Have seen nothing in the progress of this case to induce me to believe the prisoner was ever insane before the night of the murder, nor up to the time when Mr. Delano left his garden on the evening of May 26th. Saw no evidence of insanity when he was in Mr. Wormell's room nor when he walked home with Mrs. Peckham; nor was he insane in my judgment during the three days following the death of Holmes. Provided his testimony be true, I think he had a paroxysm of mania which passed off with the struggle. Think he was coming out of his insanity when he stooped to pick up his hat. Insanity may appear for ten or twenty minutes when it had never existed before, and never exist afterwards. This is a physical disease of the brain—a functional disease. It affects the mind. In this case, I should think it would have been in the prisoner's favor if he had come out and owned it and given himself up.

Have had occasion to see, examine, or treat two or three hundred insane patients during my life; there is a susceptibility to insanity in children, whose parents are insane. Do not know what proportion of the children of insane parents become insane.

Dr. Jones—re-called by the government. Never saw anything during my attendance on, or acquaintance with Mr. Andrews indicating insanity.

Dr. George S. C. Choate—sworn. Am superintendent and physician of the Taunton Lunatic Hospital; have been for 15 years, and have had charge of between three and four thousand patients. The question was then asked, What, in your opinion, are the material points in the case bearing on the subject of insanity, and what does each point have for or against insanity—hereditary insanity? Answer—The only point which appeared in the case to suggest an inquiry into the mental condition of the prisoner was the fact that his mother and some more remote relatives were insane, and transmitted to him a liability to have the same disease; insanity follows the same law as other diseases in the mode of transmission; a child born of insane ancestry inherits not the disease, but the same constitution rendering it liable to the same disease, if favorable circumstances arise for its development; the fact follows from this that the existence of insanity in ancestry proves liability only and not the disease. However strong the proof may be of hereditary pre-disposition, if it stands alone by itself, it is of no value whatever; it may

become important, however, in confirming direct testimony in a nicely balanced case; that direct testimony I do not find in the history of this case. If a man under close observation manifests no symptoms of insanity up to within fifteen minutes of an act of violence, and again under observation manifests no symptoms of insanity from a time fifteen minutes after the act, it would be conclusive to my mind that the act was not the act of mental disease; I have never known, and I do not believe that there exist cases of insanity, originating and terminating in a single act of violence. When an insane man commits an act of violence he acts either without a motive or from a *diseased motive*. The effect of a diseased motive is the effect of a delusion. The sane criminal acts from one of the ordinary motives of crime, either the gratification of some passion or the attainment of some personal advantage. The selection of time and place is an important element in forming an opinion as to the character of the act. The insane man who commits an act of violence does not choose time or place. He frequently commits the act in public, at noonday. The sane criminal, on the other hand, chooses darkness and seclusion. The conduct after the deed has an important bearing on the question of insanity. Ordinarily the insane do not conceal, and will often proclaim the deed of violence they have committed. The sane criminal almost invariably endeavors to conceal it. The Court asked the witness this question—Assuming the statement of Andrews to be true, would you consider him sane or insane? Answer—while I would not pretend to reconcile the statement of Andrews with the conflicting facts in the case, yet on the whole I should consider him sane. The preponderance of the facts excluding insanity was so great as to overbalance any doubts which he suggested by his statement.

We do not attempt to pronounce upon, or criticize the conflicting opinions above reported. To do so would be to assume ourselves experts in the science of insanity. We add that we hold any man in high honor who stands ready to promulgate views, scientific or other, which run counter to the current of sentiment among his cotemporaries. But, we respectfully submit that where one eminent in a particular branch of medical science takes a position supposed to be in opposition to that of his immediate *confrères*, and one which seems

extraordinary, to the great body of the profession, we may perhaps reasonably ask for some explanation. Can a man be admitted to be insane, for a few minutes, just long enough to commit a crime, though always perfectly sane before and after the act? We think it would be highly satisfactory to our medical community to be put in possession of the test cases, and the reasoning thereupon, which may have led to the affirmative of this question. It strikes us as the more desirable from the tenor of the following passage from the charge of Mr. Chief Justice Chapman:—

“The prisoner is a witness, and testifies as to his state of mind when he did the act. There are two things to be inquired into on this point. (1.) Assuming his statement to be true, does it prove that bodily disease had suddenly attacked him, or that he acted under the impulse of passion that became blind and furious? If it was the latter it was not insanity, and he must seek for an excuse on some other ground. On this point the opinions of the two experts are given. Dr. Jarvis testifies that the facts would indicate a maniacal paroxysm. Again he says, in regard to the prisoner's statement, ‘the facts tend to suspicion of insanity.’ He says the act of killing is itself no evidence of insanity; and it would in fact give to crime perfect impunity if the commission of crime were to be regarded as evidence of insanity.

“It is proper, also, to say that if a homicide is committed with circumstances of cruelty and atrocity, the cruelty and atrocity do not of themselves tend to prove insanity. Our statute treats these circumstances as raising the crime to murder in the first degree. And if such circumstances were regarded as evidence of insanity, it would furnish an inducement to every murderer to act with as much cruelty and atrocity as possible, in order to furnish proof that he was insane. But if the act is done without any assignable motive, you look more readily to insanity as its cause than if a strong motive were proved.

“I have spoken of the opinion of Dr. Jarvis that there might have been a sudden attack of insanity that came on without any premonition and led to the murder, and departed as soon as the murder was committed, leaving no trace behind. The opinion of Dr. Choate is directly contrary to this.

“He regards such a kind of insanity as unheard of and impossible. As insanity

VOL. III.—No. 4B

arises from bodily disease, he thinks it could not come on so suddenly, rage so violently, and then totally disappear.

“You are to judge of these opinions. The opinions of experts are mere evidence for the jury to consider, in connection with other evidence. The responsibility is, after all, on you to say whether the prisoner is guilty, or is not guilty by reason of insanity.

“I think the opinions of experts are not so highly regarded as they formerly were. For while they often afford great aid in determining facts, it often happens that experts can be found to testify to any theory, however absurd. The experts before you are gentlemen of learning, and you must judge between them.”\*

Since completing the foregoing remarks, with the quotations annexed, we have received the favor of the following letter from Dr. Jarvis, in reply to a note asking him to correct any flagrant errors in the report of his testimony. It is gratifying to perceive that Dr. Jarvis had anticipated what we presumed to be the general desire of the profession. We shall cordially welcome his proposed paper to the columns of the JOURNAL, and we trust it will be none the less acceptable for this preliminary sketch.

DORCHESTER, MASS., Feb. 1st, 1869.

*To the Editor of the Boston Medical and Surgical Journal.*

Dear Sir:—[The printed] report of the trial of Andrews reached me Saturday evening.

The report of my testimony is very incomplete, and gives a very meagre and unsatisfactory account of my opinion and statement. My evidence on the chief examination was given under the continual interruptions of the attorney general, who first objected to the use of my testimony entirely, and when overruled by the court, made it as brief and fragmentary as possible.

That which I gave in the cross examination was simply in answer to his specific questions, with no opportunity for fullness of statement or explanation. I have here done what you requested, and corrected the manifest errors in this report, but made no additions.

It has been my intention to write, for your JOURNAL, a paper on Transitory Mania, showing the opinions of the German, French, English and of some American authorities on

\* His Honor has done us the great favor of writing out for us this portion of his remarks, from his own minutes. The newspaper report is inaccurate.

this subject, and in this connection give an account of the Andrews case as illustrative.

The doctrines given by Marc, Esquirol, Castelnau, Duvergie, Maudsley, and also by Woodward and Bell, and admitted by Ray, are:—

1. That mania may appear suddenly without forewarning.

2. That it may manifest itself in a single act of violence.

3. That this act of violence may be rather in obedience to the cerebral excitement than for any specific purpose, and may therefore go beyond what would be necessary for its accomplishment; as when a French woman not only stabbed her child many times, but cut off its head. The Juris-consults held that this excess of injury was evidence of mania rather than of mere intention of murder.

4. That this mania may suddenly cease and leave no trace behind.

5. That, during the paroxysm, the maniac may be unconscious of his acts.

6. That afterwards he may have no recollection of his maniacal acts.

7. That when he returns to sanity, he may have no conscientious feelings of guilt for his maniacal acts, whatever they may have been.

Admitting the truth of Andrews's statements in prison and of his evidence in court, these conditions existed in his case. . . .

Very truly yours,

EDWARD JARVIS.

RICHMOND, IND., Feb. 19th, 1869.

MR. EDITOR,—Last May, in Washington, after the American Medical Association decided to hold its next meeting in New Orleans, I promised several eastern gentlemen to see if an arrangement could not be made for a first class steamer to take all who desired to travel that way, from Cairo to New Orleans, in good style and upon reasonable terms. My correspondence with the Mississippi steamboat men warrants me in saying that an arrangement for a party of that kind can be made, and I will be able to publish the terms by the first of April. Perhaps it might interest some of your readers if you were to say that such an arrangement is likely to be consummated.

The time from Cairo to New Orleans will be about four days, and the fare not to exceed \$35 from Cairo to New Orleans, and return, and this includes meals and state rooms. Perhaps better than this can be done, but as soon as I learn what the best terms are that can be made I will advise you.

Prof. Gross and others thought that if all or most of those going down the river could get on a first class boat the trip would be less tedious, and perhaps both pleasant and profitable.

Provision upon like terms will be made for ladies who accompany the doctors.

Very truly, &c.,

JAS. F. HIBBERD.

N. B.—We do not hold ourselves responsible for the opinions or sentiments expressed in articles we print as contributed or addressed to this JOURNAL. Newspapers which may have noticed any paper which has appeared in these columns will confer a favor by inserting the above.—EDITOR BOSTON MEDICAL AND SURGICAL JOURNAL.

THE following memoranda of interesting points which came up at the last meeting of the Suffolk District Medical Society, were obtained from the minutes of the Secretary, Dr. John Homans:

Prof. J. B. S. Jackson showed a pair of kidneys affected with cystic disease, weighing 10½ pounds, from a patient 56 years old. No full history of the case was obtained. Dr. J. remarked, that in every case of this disease that he had seen, the symptoms of renal disease were absent. The most marked case of granular kidneys he ever saw occurred in a strong, healthy teamster, who died by an accident. Both kidneys were always affected. He had never seen any specimens to compare with these.

Dr. H. I. Bowditch related a case of empyema of left chest, with dulness, great dyspnoea and failure of strength. The patient was sick five weeks; paracentesis relieved him of 4½ pints of pus, after which the lung recovered its resonance, and the boy is now doing well.

Dr. A. B. Hall related a case of the retention of a piece of lead in the bronchi for three years.

Dr. Heaton gave a similar case, of retention for seven years.

Dr. Jackson spoke of the ease with which a bit of grain, assisted by its beard, would work its way into the larynx and trachea, and, not stopping there, would frequently penetrate into the ultimate bronchules, and thence by ulceration, out through the integument, just below the clavicle. The rule is recovery. An iron nail had been reported as following the same course.

**LARGE LOOSE CARTILAGE IN THE KNEE-JOINT.**—A case of unusually large loose cartilage in the knee-joint, treated on the antiseptic system, under the care of Mr. Lister, is reported to the *Glasgow Medical Journal* and also to the *Dominion Medical Journal*, by Archibald E. Malloch, M.B., House-Surgeon to the Glasgow Royal Infirmary.

W. E., aged 20, was admitted into the Royal Infirmary on the 28th of June, 1868, complaining of slight lameness, of a "lump which moves" in his right knee, and at times of slight pain in the joint, especially when carrying any heavy article. A loose cartilage, about the size of a half-crown piece, was felt and moved freely about in the joint. The previous history of the case is interesting, as pointing apparently to its origin from the fringed processes of the synovial membrane. He dates the beginning of his complaint eight months back, when he strained his knee. . . . . Three weeks after the accident, while rubbing his knee with a lotion which he had got from a doctor, he felt a "small hard lump," about the size of a marble, above, and to one side of his knee-cap, which he could move to a slight extent from side to side. This "hard lump" increased gradually in size, and got proportionally freer in its motion, and could at all times be felt. About four months after the accident the "hard lump," which was then nearly as large as at present, could be felt at times in front of the joint on either side of the knee-cap, below which it occasionally disappeared. During the last four months it has increased in size, and is at times "lost." On ten or twelve occasions he was suddenly stopped short while walking, from inability to straighten his right leg. He would then have to sit down, and, by movements of the joint, free the "hard lump" which, he thinks, must have got between the bones. This displacement was attended with slight pain, and was followed by increase in the size of the joint.

Professor Lister determined to perform the direct operation, as the subcutaneous method would be difficult, if not impossible, from the large size of the cartilage, while he felt confident that on the antiseptic system the joint might be freely opened without risk.

On the 2d of July the cartilage was extracted. The instruments were dipped in a solution of one part of carbolic acid in six of oil. The same solution was dropped

into the incisions as fast as made. While the synovial cavity was being opened, the orifice was curtained with a sizable piece of lint wetted with the solution in order that air regurgitating into the wound might be impregnated with carbolic acid. After the operation fresh pieces of lint soaked with an oily solution of carbolic acid (one part to ten) were placed over the wound, which was left gaping to give exit to effusions. The lint was covered with cloths, which had been dipped in the solution, and lastly carbolic acid plaster enclosed the preceding application, and in turn was covered with a folded towel held in place by a bandage.

"The loose cartilage was one and a quarter inch long by one inch in greatest breadth and a quarter of an inch in greatest thickness, round at one end and more pointed at the other; one surface smooth, the other irregular with a sort of corrugated appearance."

Within the cartilage was found a layer of true bone.

July 4th.—Discharge upon the towel a minim or two. July 5th.—Two or three drops of serum. July 7th.—During last forty-eight hours discharge of about six minims of a sero-sanguineous fluid. July 11th.—Wound found to be "a granulating sore."

"July 12th.—The joint has remained free from pain except when he moved it, when 'he felt it a little.' Has slept well and eaten his food with his usual relish. The wound is somewhat more open, and there is a good deal of effusion in the joint, but no redness. Dressings, as yesterday, repeated; pulse 70; tongue clean. It appears that since his bowels were moved, two days after the operation, he has walked each day to the water closet. This circumstance, which was quite contrary to orders, probably explains the slight irritation of the joint."

July 15th.—Granulations touched with sulphate of copper.

"August 12th.—The patient left the Infirmary, with the wound quite healed, and the movement of the knee perfect.

"Sept. 19th.—The patient states that he worked the day after leaving the Infirmary, and felt no pain in the joint; the following day, however, it was much swelled; that he has worked every day since, and has not suffered any pain. There is still a little effusion in the joint, but no lameness."

Carbolic acid dressings were continued from the time of operation till the wound was healed.

THREE cases are reported from Australia, in the *London Medical Times and Gazette*, of *snakebite* treated by Prof. Halford's method. All three had previously been treated locally by the patients themselves. One patient had sucked the wound, and applied ligatures above the bitten finger. The second had merely pricked and incised the wound. The third had sucked the wound and used the ligature. The first mentioned had the remedy applied promptly, and got no further than extreme drowsiness, when she began to rally. The second passed into a state of extreme stupor, from which he soon awoke after the second injection of ammonia. The third was comatose, but "in a very short time" after the ammonia was thrown into a vein, became sensible.

The second of these patients had the "liquor ammoniæ fortis" injected into the saphena vein, and beneath the skin elsewhere; in all, about (12) minims.

Prof. Halford mentions, with reference to this case, that the liq. ammon. fort. should be diluted before injection in such cases with two or three times its quantity of water, and of this mixture from twenty to thirty drops should be injected into one of the larger veins. The syringe, he adds, should be carefully introduced, so as to give the ammonia a fair chance. He disapproves of merely throwing the injection under the skin, and believes that after the injection of ammonia there is no necessity for resorting to the use of stimulants."

**CARBONIC OXIDE.**—One more *quære* we would offer with reference to the French experiments upon cast-iron stoves *versus* carbonic oxide. Was *anthracite* coal burned in the stoves, or the bituminous coal commonly used in France?

At the recent Annual Congress of German Naturalists and Physicians, in Berlin, in the section for Midwifery and the Diseases of Women, a discussion took place on the local treatment of the womb and its cavity by sounding, intra-uterine pessaries, dilatation, incision, injections, &c. Prof. Credé, of Leipzig, said that he had seen bad acci-

dents caused by the introduction of the sound, such as spasms, fainting fits, severe pain, hæmorrhage and inflammation, especially in hysterical women. He could not recommend the extended use of intra-uterine pessaries, and of laminaria and spongetents he had only rarely seen good effects. Incision of the cervix had proved useful in his hands for menstrual colics and sterility, but the patients ought to be carefully watched. Injections he had quite given up, as they seemed always to cause inflammation and severe pain. Prof. Hegar, of Freiburg, said his results with all the procedures mentioned were more favorable. Injections into the cavity of the uterus he only used for hæmorrhage, especially after abortion. Dr. Kristeller, of Berlin, said it was not necessary to be very timid in these matters. Since employing Marion Sims's speculum, he had never seen bad accidents after injection; he preferred, however, to apply remedies by means of camel-hair brushes and cotton to the diseased parts. He often used the sesquichloride of iron and pyroligneous acid, without any trouble afterwards.

In the section for Infantile Diseases, Prof. Ebert, of Berlin, spoke on temporary blindness in the course of acute infectious disorders, such as typhoid fever and nephritis scarlatinosa. The patients lost their sight suddenly, and regained it as suddenly, within from twenty-four to forty-eight hours afterwards. There was neither congestion nor inflammation of the retina, nor paralysis, such as we observe it after diphtheria. In one case which ended fatally, the brain was found highly œdematous, and he thought temporary œdema of the centre was the cause of the blindness in the cases mentioned.

In the section for Lunacy, Dr. Meschede, of Schwetz, read a paper on heterotopy of the grey matter in the medullary fibres of the cerebellum, in an epileptic lunatic; after which Dr. Jessen spoke on physical double perception, which was owing to temporary incongruity of the action of the two hemispheres, whereby a double perception was caused, the weaker one of which was confounded with a reproduced perception of recollection.—*London Med. Times and Gazette*.

In the *London Medical Times and Gazette* a Case of Larval Tapeworms in the Human Brain is reported by C. Lawrence Bradley, F.R.C.S., surgeon to the Pentonville Prison. The patient had phthisical

symptoms with diarrhoea, and died from exhaustion. The *post-mortem* examination gave the following results:—Body emaciated. Head: Pachionian glands considerably developed, thinning the dura mater and indenting the calvarium in the mesian line. Subarachnoid effusion upon the surface of the hemispheres. On removing the pia mater numerous cysticerci were discovered packed separately between the convolutions of the hemispheres. They appeared as bladders distended with fluid, the size of filberts, some transparent, others more or less opaque. There was one in the meshes of the choroid plexus in each lateral ventricle, and one in the third ventricle, smaller ones also between the laminae of the cerebellum. Altogether, I estimated their number at twenty. There were none found in other organs. The lungs were tuberculous, but without vomicae.

The case is interesting from the entire absence of cerebral symptoms, for during the period referred to the prisoner never complained of pain in the head, giddiness, or other symptoms of cerebral irritation, and he retained his mental faculties unimpaired until just before his death.

CASE OF COMPLETE EXTIRPATION OF THE TONGUE, FOR EPITHELIAL CANCER, WITH CLINICAL REMARKS. By GEORGE F. FENWICK, M.D., Professor of Clinical Surgery, McGill University. . . . On Friday, the 20th of November, 1868, the patient—A. B., aged 45—having been put under the influence of chloroform, the operation was performed by Dr. Fenwick, assisted by Drs. Campbell and Bell (of Ottawa). The steps of the procedure were as follows:

An incision, about one inch in length, was made below the chin, exactly in the mesian line, through skin, fascia and muscle, down to the floor of the mouth; a very long curved needle in a handle was then passed through this into the mouth, emerging to the right of the frænum linguæ and close to the root of the tongue—this needle carried a strong thread to which was attached the chain of the *écraseur*. The chain of the *écraseur* thus introduced into the mouth was passed completely round the base of the tongue, being pressed back as far as possible by Dr. Campbell. The tongue was then transected by a strong cord and drawn well forward out of the mouth. The instrument was locked, and constriction immediately commenced. Fifteen seconds was allowed to elapse between each click, and at the end of nine minutes

and thirty seconds, the operation was found to be complete. The organ was then removed from the mouth by the attached cord and the operation was finished. The bleeding throughout was very slight indeed. On examination of the tongue it seems as if all the parts cut through were quite healthy.

He was put to bed and kept supplied constantly with small pieces of ice in the mouth. By 10, P.M., whatever oozing there had been during the day had entirely ceased.

Dec. 1st.—Leaves the Hospital to-day. He can now readily swallow such food as soft boiled eggs, &c. He can articulate wonderfully well, being readily understood in almost anything he says. The wound has nearly all cicatrized over.

Subsequently Dr. F. had heard from his patient through Dr. Bell, of Ottawa. The tongue had entirely healed, he was able to swallow solids, and his speech was daily improving. His general health was very good, but on the right side of the neck the sub-maxillary glands had become swollen and inflamed. This was attributed by his surgeon to cold which followed after a drive into the country.

VERTICAL DISLOCATION OF PATELLA. By J. F. NOYES, Professor of Ophthalmology in Detroit Med. College.—About two months ago I was called in haste to see a healthy-looking young girl, eleven years old, whom I found suffering from an injury to the knee. Walking along the sidewalk, she said, she had slipped, and fell, striking the “kneecap” against the edge of the curbstone. On getting up, she could not bend the knee, it pained and hurt her so much. On examination, I found the leg flexed and fixed in that position. The patella was turned round on its lower axis, so that its inner edge rested on the outside of the trochlea of the femur, and its outer edge presented immediately under the skin, forming a hard, prominent ridge, with deep depressions, existing upon each condyle, and the extensor muscle in a state of extreme tension.

The objective signs in this dislocation were characteristic and unmistakable. . . .

Most surgeons appear to agree, if I mistake not, that the reduction of this luxation is to be accomplished by first flexing the leg and thigh strongly before extending it, and, indeed, it appears to have been accomplished by flexion alone. A case is related in Sir Astley Cooper’s work. It is stated there that Mr. Mayo, the surgeon,

overcame the difficulty by bending the knee to the utmost, so that the patella was drawn entirely out of the groove in which it was lodged.

But it does seem unreasonable to advise an attempt at reduction while the leg remains flexed, or the bending of the knee previous to extending it, since this must increase the tension, and thus add to the difficulty. Acting in accordance with such advice, however, I attempted at first the reduction in this way, that is, by applying force to the bone, while the leg was in the flexed position in which I found it; but I failed in the manœuvre—the patella would not budge at all—it remained as firm and immovable as if it formed a part of the femur itself. It now occurred to me that if I should with sufficient force very suddenly extend the leg from its then existing position to the very utmost, and by so doing get the advantage, or in advance, so to speak, of any contraction of the quadriceps, I should most likely accomplish my object. This I did in this manner: placing my left hand above the “kneecap,” with the other I brought the leg suddenly and quickly out into a straight position, when, with a gentle push with the left hand, the “kneecap” went into place with ease, and to the great relief of the patient, and in a few days she was walking about again, as well as before the accident.—*Detroit Rev. of Med. & Phar.*

A HOSPITAL patient in Dublin, who was in advanced phthisis, was suddenly attacked with hæmoptysis, and discharged about a pint of dark-colored blood; he complained that he was suffocating, and in less than five minutes he was dead. . . . At the autopsy, the left lung was found to be extensively solidified, and in the apex were found two large cavities; these communicated with the bronchial tube by an abrupt termination of the latter; both contained dark clotted blood, but the posterior of the two was distended with it; and on carefully examining the cavity, he found a large vessel eroded, and hanging by one extremity into the cavity. He could pass a probe through it with facility; a little plug was found in the open vessel. The bronchial tubes were full of blood.—*Dublin Medical Press and Circular.*

ABSCESS NEAR THE RECTUM AND FISTULA IN ANO.—Mr. Holmes Coote, Surgeon to St. Bartholomew's Hospital, in an article on this subject, in the *Dublin Medical Press and Circular*, says:—

“How should we treat the fistula? In cases where there is no external aperture an operation is rarely required. When the fistula is of the usual length and direction, and the patient's health fair, the employment of the director and the curved bistoury is indicated; but in those cases where the patients are delicate and tuberculous disease of the lungs is suspected, I very much prefer the use of the ligature. A long steel probe (armed with a silken thread attached to the side of the probe, which is removable) is introduced into the rectum along the fistula; the point of the probe is then seized by an instrument introduced with the forefinger per anum, and withdrawn, carrying with it one end of the ligature. The two ends of the silk, including the soft parts between the fistula and the anus, are finally tied, but loosely, so as to exert no pressure. In three to six weeks the ligature cuts its way out, the wound healing from the bottom. In this operation there is no pain.”

PREVENTION OF TUBERCLE.—Henry MacCormac, M.D., of Belfast, author of a treatise on consumption, says:

“Since I commenced the noble study of medicine, during the protracted period which has elapsed, I have rarely given less, on an average, than six hours out of twenty-four to study and composition. I have accumulated, as will be readily conceded, a large amount of various information. I have written on most branches of medical investigation, and I believe have carefully pondered all. I have striven earnestly to further the great cause of humanity, and to abate its manifold inflictions. The result has been an intimate conviction, that *I have determined the real and only possible source of tubercle*, and to enhance and intensify the belief, that the profession, if they will only energetically and uniformly enforce the habitual respiration of air not pre-breathed, may, within a very brief period, bring the ravages of tubercle to an absolute and permanent close.”—*British Medical Journal*, p. 110. Jan. 30, 1869.

TREATMENT OF MALIGNANT PUSTULE.—Dr. Caspar in Stassfurth has used liq. ammoniæ causticus in several hundred cases, and reports that the only instance of death was that of a woman far advanced in pregnancy, who vomited the remedy as often as administered. He gives to children from one to three drops, to adults five drops, in sweetened oatmeal-gruel, every hour by day and

night. He applies dilute liq. chlorini to the ulcer, but attaches little importance to the application; and continues the treatment until the inflammation in the neighborhood of the ulcer ceases to spread.—*Deutsche Klinik*. 1. 1869. D. F. L.

HEREDITARY ERYSIPELAS: ELECTRICITY.—Dr. Schwalbe in Pläfficon reports a case which he observed in Costa Rica, in which three generations were implicated. The grandfather, from his 18th year, had suffered almost every month from erysipelas of the legs, in consequence of which an enormous elephantiasis had developed. He died at 80. The father, since his 18th year, has had several attacks of erysipelas yearly; he also has elephantiasis of both legs. The eldest son had suffered similarly from the same age; and the youngest, aged 18, presented himself to Dr. S., with his first attack of erysipelas. In each person, the separate attacks were accompanied with violent fever and severe pain, lasting three or four days. Dr. S. applied the electric brush for ten minutes to the legs of the youngest; the relief to the pain was immediate and great.

Another case of erysipelas had lasted only twenty-four hours. The skin of the cheeks was much swollen; redness extended behind the ear and to the forehead; the cheeks were dotted all over with little circumscribed exudations, some of which had become vesicles. Fever and pain great. + pole (sponge) to the root of the facialis, - pole (brush) to the affected portions of skin for ten minutes. This was followed by much relief to the pain and tension. In twelve hours there was hardly any pain left, and the exudations had disappeared. The brush was again applied for ten minutes, and the next day the patient was well, not having had to give up her work, which was that of a house-servant.—*Allg. Med. Central Ztg.*, No. 5. D. F. L.

An apparatus for giving an alarm in case of the presence of carbonic oxide or coal gas\* in a room, it is reported, has recently been invented by a Prussian. It consists of a galvanic battery with a bell and a glass tube filled with liquid chloride of palladium. This metallic salt is extremely sensitive to the pressure of carbonic oxide gas. A small quantity of the gas will at once throw down some of the metal from the solution, and this precipitate collecting in the bottom of the tube, at once establishes a connection in the current of electricity, and the violent

ringing of the bell will warn the sleeper of his danger.—*Med. and Surg. Reporter*.

In an elaborate article on Hospital Gangrene as it Manifested itself in the Confederate Armies, during the American Civil War, 1861-1865, by Joseph Jones, M.D., Professor of Chemistry in the Medical Department of the University of Louisiana, the author says:—

In its mode of origin, hospital gangrene may be viewed in four ways:—

1st.—As a local disease, communicable only by contact with animal matter in a certain state of change or decomposition.

2d.—As a constitutional disease.

3d.—As both local and constitutional in its origin.

4th.—The disease may arise from the action of a specific poison, which acts in a manner similar to that of smallpox, measles or scarlet fever.

The third proposition expresses most nearly our views; for it is capable of demonstration by cases and instances which I have recorded and observed:—

First—That hospital gangrene may arise in those exposed to the exhalations from gangrenous wounds, without any abrasion of the surface.

Second—That hospital gangrene can be communicated through the atmosphere to wounded surfaces, without any direct application of the matter.

Third—That in some cases, after the wounds had been subjected to the action of the cause of hospital gangrene, a certain period of time elapses before the disease appears.

Fourth—That in some cases poisonous matters are so rapidly absorbed from the infected atmosphere of the crowded wards, and the diseased action is propagated with such rapidity from the local injury to the central organs in constitutions broken down by bad diet, exposure, and by the influence of the foul emanations from the wounded and sick crowded into badly ventilated hospitals, that death results from the effectual and almost immediate poisoning of the system, before the local disease has progressed to any extent.—*N. O. Journal of Medicine*.

DR. BROWN-SEQUARD will not enter upon the full duties of his chair of Comparative and Experimental Pathology before November next. The government has decided to build a *laboratoire* for him, near the School of Medicine in the Garden of the *Hôpital des Cliniques*.

\* The two are not synonymous.—Ed. B. M. & S. J.

## Medical Miscellany.

WE have received from the *Sacramento Daily Union* of January, 18th, 1869, a "slip" containing a report addressed to L. J. Deal, M.D., of Philadelphia, by Thomas M. Logan, M.D., on the question of the feasibility of cultivating the cinchona tree in California. Dr. Logan says:—

"Considering, therefore, the peculiarity and variety of the climatic conditions and vegetations of California, it can scarcely be doubted but that a locality may be found here for the propagation of the cinchona as readily as in India, where its culture has been attended with success."

Dr. Logan, being a member of the State Board of Agriculture of California, promises the coöperation of that Board in any plan which may further the introduction and cultivation of the cinchona tree in that State; and the Sacramento Medical Society has voted to use every effort in the same direction.

**ANALYSES OF AIR.**—The Metropolitan Board of Health of New York are now making analyses of the air of theatres and other places of public assembly. We hope they will include hospitals in their examination.

**HAIR DYES AND COSMETICS.**—Some hair dyes are innocent enough, and do not require any warning on the part of the medical man; others are dangerous, and the use of both kinds requires tiresome manipulations. Among the innocent kinds we may mention infusion of beans, and cypress cones, of willow bark, and ivory black. Among the second kind may be enumerated sulphate of lead, mingled with hydrate of lime and water; carbonate, acetate and sub-acetate of lead in solution, to which dilute sulphuric acid is added, and which dyes the hair a dark brown. The salts of silver, too, are much used to blacken the hair, but they make the scalp irritable, and burn the skin and the hair follicles, and tend to produce baldness. . . . Certain substances are used for changing the color of the skin: for example, the white cosmetics, bismuth, or pearl white, is sometimes mixed with a notable quantity of arsenious acid, when it is dangerous; but when this substance is purified, it is innocent. . . .  
—*Dublin Medical Press and Circular.*

IN Dr. Livingstone's account of his rencontre with the lion, when his arm was fractured, he writes:—"I saw the lion in the act of springing on me. I was on a little height; he caught my shoulder as he sprang, and we both came to the ground below together. Growling horribly close to my ear, he shook me as a terrier dog does a rat. The shock produced a stupor like that which seems to fall on a mouse after the first shake of the cat. It caused a sort of dreaminess, in which there was no sense of pain nor feeling of terror, though quite conscious of all that was happening. It was like what patients partially under the influence of chloroform describe, who see all the operation, but feel no knife. This singular condition was not the result of any mental process. The shake

annihilated fear, and allowed no sense of horror in looking round at the beast." This peculiar state is probably felt in all animals killed by the carnivora.—*People's Magazine.*

**CARBONATE OF LIME IN PERTUSSIS.**—Dr. Snow, of Providence, R. I., has suggested the use of carbonate of lime in whooping cough, and in all cases it has apparently produced a marked effect in diminishing the frequency and severity of the paroxysms. Small quantities of the carbonate of lime are placed in saucers in the room where the child sleeps; merely sufficient to make the odor perceptible.—*Medical Record.*

WE have at the disposal of those wishing them a few copies of a "Memorandum for the information of persons desirous of entering the Medical Corps of the U. S. Army."

It has been calculated that on some part or other of our planet an aërolite descends daily.

## MEDICAL DIARY OF THE WEEK.

MONDAY, 9, A.M., Massachusetts General Hospital, Med. Clinic. 9, A.M., City Hospital, Ophthalmic Clinic.

TUESDAY, 9, A.M., City Hospital, Medical Clinic; 10, A.M., Surgical Lecture. 9 to 11, A.M., Boston Dispensary. 10-11, A.M., Massachusetts Eye and Ear Infirmary.

WEDNESDAY, 10 A.M., Massachusetts General Hospital, Surgical Visit. 11 A.M., OPERATIONS.

FRIDAY, 9, A.M., City Hospital, Ophthalmic Clinic; 10, A.M., Surgical Visit; 11, A.M., OPERATIONS. 9 to 11, A.M., Boston Dispensary.

SATURDAY, 10, A.M., Massachusetts General Hospital Surgical Visit; 11, A.M., OPERATIONS.

**ERRATA.**—In last week's issue, page 39, 2d column, line 38, for "quantity" read *gravity*; page 40, 1st column, line 11, for "pleuras" read *pleura*.

**TO CORRESPONDENTS.**—The following communications have been received:—Treatment of Diseases of the Lachrymal Sac.—Interesting and Unusual Cases of Traumatic Injury of the Eye.

**PAMPHLETS RECEIVED.**—Report of the Pennsylvania Hospital for the Insane, for the year 1868: by Thomas S. Kirkbride, M.D., Physician-in-Chief and Superintendent.—Eleventh Annual Report of the Chicago Charitable Eye and Ear Infirmary, presented by the Board of Surgeons, for the year 1868.—Reports of the Trustees and Superintendent of the Butler Hospital for the Insane, Providence, R. I.—First Annual Report of the Orthopaedic Dispensary, located at 1299 Broadway, New York.

**DEATHS IN BOSTON** for the week ending Saturday noon, February 20th, 124. Males, 61—Females, 63.—Accident, 4—apoplexy, 3—inflammations of the bowels, 1—congestion of the brain, 1—disease of the brain, 2—inflammation of the brain, 1—bronchitis, 3—cancer, 5—consumption, 18—convulsions, 6—croup, 2—debility, 2—diphtheria, 2—dropsy, 1—dropsy of the brain, 3—epilepsy, 1—erysipelas, 2—scarlet fever, 11—typhoid fever, 7—gangrene, 1—disease of the heart, 1—disease of the hip, 1—homicide, 1—disease of the kidneys, 1—disease of the liver, 2—congestion of the lungs, 1—inflammation of the lungs, 13—marasmus, 1—measles, 1—old age, 5—paralysis, 3—peritonitis, 2—premature birth, 3—disease of the spine, 1—softening of the stomach, 1—syphilis, 1—teething, 1—tumor, 1—whooping cough, 1—unk'n, 8.

### CEREBRAL AMAUROSIS.

By Dr. IG. MEYER, K.K. Kreisphysicus in Steyer.

[Translated for the Journal by B. JOY JEFFRIES, A.M., M.D., from the Vienna Weekly Medical Journal.]

[TRANSLATOR'S NOTE.—In our communities, even physicians who pay special attention to diseases of the nervous system, have not yet rendered themselves familiar with the use of the ophthalmoscope, and the healthy and morbid appearances revealed by it in these complaints, when of cerebral origin. Consequently, the specialist is called upon to make the ophthalmoscopic examination, report what he finds, and give his prognosis, although if the result is negative, certainly the case does not belong to ophthalmic medicine and surgery. To make a careful examination, the surgeon must be familiar with the use of the *upright* as well as *inverted* image. This takes more time and patience than any physician in general practice is willing to give to it, and he therefore, upon the occurrence of ocular symptoms, immediately consults the specialist. For the present at least, then, it is necessary for us ophthalmologists to be familiar with the ophthalmoscopic signs connected with cerebral diseases. I have therefore translated the following memoir of Dr. Meyer for the convenience of my brother physicians when studying up a special case. It reviews a large number of recorded cases, and gives some general laws of the connection of amblyopia and amaurosis with cerebral diseases. I think this digest, for instance, would have been of great assistance in such a case as the very interesting one lately reported by Dr. S. L. Abbot, in this JOURNAL. I do not imagine many will take the trouble to read this all through, particularly as it must appear in detached parts, but I think it will be worth while to glance it over, so as to know where to look for some assistance in making up one's diagnosis and prognosis. I would, in connection with this, call attention to the

VOL. III.—No. 5

memoirs of Græfe, Bouchut, Galezowski, Beaumetz, Hughlings Jackson, &c.

B. J. J.]

Ophthalmoscopic examination has shown, in a series of amblyopic and amaurotic blindnesses, material alterations in the retina and optic papilla, as also in their circulation, which must be considered the direct cause of the amaurosis. In very many cases, however, the ophthalmoscope does not reveal anything, and the immediate cause of the blindness must be looked for in the pathological condition of the brain and spinal cord, which may often be the case when *secondary* changes are afterwards seen in the papilla by the ophthalmoscope.

In general, it is not difficult to determine the existence of cerebral amaurosis. The appearance of undoubted brain-symptoms, the absence of special amaurotic changes in the retina, optic nerve or orbital structures, the persistence and increase of the disease, generally indicate or determine the fundamental complaint. It is much more difficult, however, to determine precisely the character of the disease within the cranium, and particularly its locality.

The appearances which indicate the cerebral origin of amblyopia and amaurosis are the generally observed symptoms of brain disease. Amongst these are specially reckoned—headache, functional anomalies of the brain (of the sensation of perception, by the eye, by the other senses, and mental functions), giddiness, subjective abnormal sensations, loss of sensation (anæsthesia and analgesia), difficulties of voice and articulation, anomalies of motion dependent on the brain (convulsions, cramps, contractions, paralyzes), apoplectic and epileptic attacks, unconsciousness, coma, lack of and troubled sleep or great somnolency: besides these, symptoms in other organs, especially bad digestion, vomiting, spinal reflex attacks, anomalies of the genital functions, and also in the composition of the blood and nutrition.

By grouping a number of cases of cerebral and spinal amauroses, which after fatal termination were subjected to autopsy, I

[WHOLE No. 2140.]

will endeavor to connect the symptoms presented with the character and locality of the disease, in order from these, considered with the reports of good pathologists on the phenomena of organic cerebral troubles, to gather, if possible, some data for the diagnosis of these so often very obscure complaints.

The observations upon which this memoir is based number 143, being cases gathered from literature, of cerebral disease in which amblyopia or amaurosis was a specially noted symptom, either in the commencement or the course of the complaint. In 83 of the 143 cases, tumors were developed either in or on the brain. Of these tumors, 22 were in the cerebral hemispheres; in the lateral ventricles, 3; in the optic thalami, 3; in the corpora quadrigemina, 2; in the tentorium, 3; at the base of the brain, 9; in the pons Varolii, 10; in the hypophysis, 22; in the cerebellum, 2; multiple tumors in the cerebrum, 7. Besides the tumors, processes of exudation were seen 8 times, especially at the base of the brain; 8 times purulent formation and cerebral abscess; 11 times softening of the brain; 3 times induration; 7 times apoplectic deposits; 8 times aneurism of the cerebral arteries; once hydrocephalic appearances; 8 times affections of the spinal cord, and 6 times disease of the cranial bones.

The amblyopia or amaurosis seen in these cases affected mostly both eyes, commencing generally with reduced vision or blindness on one side, and involving, in the course of the disease, the other. Several times blindness is reported only on one side, and was explainable in some cases by pressure from apoplectic collections, &c., upon one or the other optic nerve from the chiasma or upon one optic trunk. For instance, in one case aneurism of the left arteria communicans pressing on the left opticus produced blindness only on the left side, as also an abscess in the left anterior cerebral lobe, and an apoplectic clot in the right anterior cerebral lobe caused blindness on the respective sides. Monocular amaurosis was also noticed where there were tumors situated in one half of the pons, in one crus cerebri, optic thalamus, or corpus striatum, mostly on the affected side; to this, however, there were exceptions. If the central portions of the brain were affected, or if the disease was at the base, blindness was generally binocular. In a case of Friedreich's, a tumor reached from the left posterior cerebral lobe to the base and thalamus, and yet there was paralysis of the right side and loss of vision of right eye.

With tumors of considerable size in these parts, there was generally more or less extensive paralysis of the opposite half of the body, and sometimes blindness on that side. Tumors in the corpora quadrigemina do not always destroy vision. In one of Bright's cases there was a tumor here situated, in a person who had been mentally and bodily weak from youth up, and yet no other symptoms than pain in the forehead and temples, dizziness and uncertain visual impressions. In a case reported by Zschokke (*Deutsche Zeitschr. f. Staatsarzneikunde* 1. Band. 1853, p. 411), there was a medullary carcinomatous tumor at the origin of the optic nerves in the globuli medullares and corpora quadrigemina, considerable fluid in the cerebral ventricles, and numerous spiculae and plates of bone in the dura mater and basilar surface of the cerebrum, absence of the olfactory nerves, scarcely a trace of chiasma and infundibulum visible; in this case there was at first dimness of vision, lasting for half a minute and then passing off, but finally complete amaurosis. Of course there was absence of smell; and frequent faintings, with numbness of the body, occurred. In a case of tumor in the hemisphere, in a tumor of the hypophysis, as also in a case of aneurism of the carotis cerebialis, occasional very temporary dimness of vision took place.

Sudden blindness was seen in a case of hydatids in the left lateral ventricle, a tumor in the right median cerebral lobe, an abscess in the left hemisphere of the cerebrum, and also in a case of encephaloid of the right posterior cerebral lobe. Greatly disturbed circulation, producing hæmorrhage in the optic sheath or in the interior of the eye, may have been the cause.

So soon as tumors produce pressure upon the organs at the base of the brain, they generally affect vision. There are numerous cases where exudations at the base of the brain and disease of the hypophysis were followed by amaurotic blindness. Tumors and hardening of the hypophysis occurred in twenty-two of the above cases, causing amaurosis. Engel reports seven cases in which blindness occurred (*Diss. de Hypophysi Cerebri et Infundibulo*, Vienna, 1839). The pressure on the chiasma and its consequent atrophy and degeneration sufficiently explain them. Other processes act in the same way; for instance, exudative processes at the base. Danielssen (*Zeitschrift d. Gesell. der Aerzte in Wien*. 9. Jhrg. 2 B.) reports a case in which in a leprous person the chiasma opticum was surrounded by a pretty firm, thick exuda-

tion, which had its seat in the serous tissue of the tunica arachnoidea and caused pressure and stretching of the optic nerve, and hence piercing pain in the right eye, great photophobia and gradual loss of vision. There were also in this case pains partly deep in the head, partly in the hands and feet, with hyperæsthesia of these parts. Prof. Türck has made some interesting observations upon affections of the chiasma (*Sitzungsber. der Math. Naturw. Classe der Kaiserl. Acad. der Wiss.*, Jahrg. July, 1852). His first observation was a compression of the optic nerve before the crossing, by the arteriæ corporis callosi in a cancerous tumor of the hypophysis. A second observation was compression of the optic tracks by the arteriæ communicantes posteriores running nearly diagonally across under them. Türck also calls attention to the pressure on the chiasma from severe acute or chronic hydrocephalus, producing a vesicular swelling of the tuber cinereum. In some of the cases of hydrocephalus with marked cerebral pressure, but in which the tuber cinereum was not swollen, there was no amaurosis. Türck found in most of these amaurotic cases an exudative process, with nucleated cell-formation in the chiasma and on the optic tracks up to the corpus geniculatum externum. In Truka's history of amaurosis there is a case of Kaltschmied's noticed (Jena, 1752), in which a woman, who had been struck on the head ten years previously, suffered from severe pain in the head; several months after, upon sneezing, a pound of lymph was evacuated, then amelioration for some time, and finally, a year before death, headache and amaurosis occurred. The optic nerves were found pressed and flattened by a large collection of water in the whole brain and under the cerebral meninges; the plexus choroideus also varicose.

Inflammatory processes in the meninges of the brain frequently cause amaurosis, especially if exudations collect at the base of the brain and there produce pressure on the optic nerves. By similar pressure, hydropic collections in the lateral ventricles, as also at the bottom of the third ventricle, lead to amaurosis. These cases are mostly met in young persons and children disposed to hydrocephalus. Of eight such cases of amaurosis, one was 3 years, three between 10 and 20, and two between 20 and 30 years. The largest amount of exudation was in the region of the chiasma. Such cases especially followed acute exanthemata (scarlet fever).

Next to the inflammations, we have cases

of *pus* and *abscesses* in the brain, where amaurotic blindness occurred. Of 8 such cases (observed by Clerk, Burserius, Abercrombie, Bateman, Bennet, Henkel) the locality was generally (7 times) in the hemispheres; once, namely, in Burserius's case (cited by Abercrombie in his *Diseases of the Brain and Spinal Cord*), the pus was in the cranium and down to the bottom of the orbit. This patient had a tumor about the brow, lids and cheek of the left, diseased side, with pus formation. Possibly, therefore, the purulent deposit within the cranium was secondary. Wunderlich states that abscess of the brain is accompanied more rarely by marked disturbance of the senses, especially of sight, but that abscesses in the anterior lobe are more apt to be followed by trouble of vision.

Amaurosis frequently accompanies softening of the brain. In 11 cases (observed by Gericke, Marcusen, Ravitz, Düsterberg, Andral, Bennet, Meyer, Romberg) the softening was 4 times in the central portions of the brain and at the base; 3 times in the anterior lobes of the hemispheres; 3 times in the optic tracks and thalami, and once in the medulla oblongata. In a case of Ravitz's (*Casp. Wochenschr.*, 1851, 28 and 29), the right optic track and thalamus were superficially softened. In this patient, a man aged 25, there was complete blindness *left*, and hearing, smell and taste less on this side, besides paralysis of the left ocular muscles and diminished mobility of the left half of the body. In a case of Düsterberg's (*Casp. Wochenschr.*, 1846, 14), the left lateral ventricle was greatly distended, the surrounding cerebral substance, the left optic track and thalamus softened, and on the left petrous bone, where the ganglion Gasseri lies, four stactite points of bone compressing the ganglion, which was flatter, softer and larger. The patient, a man aged 28, suffered from left supra-orbital neuralgia and neuralgia of the second and third branches of the trigeminus. There was amaurosis of the left eye, trembling of the lower limbs, dizziness and convulsions, with unconsciousness; paraplegia and sopor accompanied it. If the softening affects the median portion of the base of the brain, blindness occurs on both sides. A case observed by me was that of a servant woman, aged 38. Menstruation appeared first at 22 years of age, was always irregular, and was absent for two years before the patient's entrance into the hospital. A year previous she had occasionally suffered from (rheumatic?) pains in the head, dizziness, ring-

ing in the ears, optical hyperæsthesia (sparks, flashes, colors) and diminution of vision. Upon reception, there was in both eyes only qualitative perception of light; iris had very slight mobility; pupils dilated. In addition, restless nights, heavy dreams, frequent palpitation (without discoverable organic disease). With cooling remedies and purgatives (calomel), the headache ceased. In the further course of the disease there were frequent pains in the abdomen, and diarrhœa. Vision decreased, till finally perception of light vanished. In the course of half a year death followed, with convulsions or stupor; after, however, pneumonia on the right side, severe vomiting and diarrhœa. The pia mater was found infiltrated with serum, with difficulty separable, the corpus callosum, fornix and anterior commissure softened, the choroid plexus and venous branches very empty, the corpora striata softened posteriorly, both optic thalami swollen, strewn with reddish points, the back part of the corpora quadrigemina atrophied, superficially eroded and softened, the base of the fourth cerebral ventricle softened, as also the cortical substance in the posterior lobes of the cerebrum; the hypophysis very much filled with blood, and capillary apoplexy in its back part, fatty degeneration of muscle of the heart in the right ventricle.

[To be continued.]

### CLINICAL LECTURE ON ULCUS ROTUNDUM VENTRICULI.

By PROFESSOR OPOLZER.

[Translated for the Journal from the Allg. Med. Zeitung of Vienna, by D. F. LINCOLN, M.D.]

THE patient spits a great deal, which is occasioned by a sympathetic irritation of the nerves of the mucous membrane of the mouth. It is a fact, that in diseases of the stomach, large quantities of the fluids of the mouth are secreted, and this statement includes the saliva as well as the secretion of the mucous membrane of the mouth. When the mucus is in excess, the reaction is acid. It was formerly supposed that the fluid of pyrosis was nothing else than intestinal saliva (Bauchspeichel). But if this were the case, the fluid in the mouth would necessarily contain gall. The fluid of pyrosis is simply an excessive quantity of very dilute saliva, containing a very small amount of bityalin and sulphocyanide of potassium (Rhodankalium).

A second symptom of perforating ulcer of the stomach is the pain in the scrobicu-

lus cordis, usually increased by pressure, and generally beginning to be felt when digestion commences. This disease is more common than is imagined, for most cases of cardialgia may be referred to it. The cicatrices of this ulcer are found with especial frequency in the stomachs of old women. Most patients cannot bear acid and fatty articles of food at all. Some bear meat more easily, others farinaceous food; and it is interesting to remark that certain patients will bear only certain articles, as for instance, only ham, or only raw beef—which should be prepared by chopping fine and adding lemon-juice (citronensaft) and salt. But it is always well, first to put the meat into hot water, in order to coagulate the cysticercus cellulose, if for no other reason. Sour milk, which contains casein in a state of very fine subdivision, is the best diet for this class of patients.

Tenderness upon pressure in the scrobiculus may be absent, when the ulcer is on the posterior wall of the stomach, or when through age it has grown callous. But beside the cardialgia and the sensitiveness below the xiphoid process, the patients suffer pains of other kinds, which may be caused by the irritation of the food, the movements of the stomach, or the pressure of gases within the stomach.

A continuous pain, in a case of round ulcer of the stomach, is caused by the super-vention of peritonitis. In such cases the tenderness is great and increases steadily; there is fever, vomiting and much distention of the belly. The danger of perforation is then extreme, and the friends of the patient ought to be made aware of it. This change in the character of the pain requires a change of treatment.

Pain, however, occurs in other diseases of the stomach, especially in cancer and hæmorrhagic erosions; and other symptoms are necessary to a diagnosis of ulcer. Such are eructation, vomiting, hæmatemesis and heart-burn. Eructation is a vomiting of wind; it is necessary to observe by the odor, whether it is caused by the food consumed, or by the presence of sulphuretted hydrogen.

When the substances vomited contain lactic, acetic or butyric acid, an abnormal state of the digestion is present, which gives rise to a gastric catarrh with or without fever. The vomiting of blood is not of itself an adequate proof of the presence of a round ulcer of the stomach, since it also occurs when a cancer ulcerates. Yet in most cases of cancer of the stomach a movable tumor is demonstrable in the region of the stomach,

while the tumor which may arise from perforation and peritonitis is not movable. Fatal hæmorrhage may occur as the result of arrosion of the arteria coronaria sinistra; less frequently of the gastro-epiploica, the gastro-duodenalis, the vasa brevia ventriculi and the art. lienalis.

An important symptom in gastric ulcer is the heart-burn, a sensation as if a flame were rising from the stomach to the œsophagus and extending up over the throat; which may be accompanied with an increased secretion of the fluids of the mouth, and the eructation of a sour or rancid fluid. Cancer of the stomach is also very frequently accompanied with heart-burn. This is commonly caused by the formation of lactic, butyric or acetic acid in the stomach, but in its worst form it is accompanied by rancid eructation, showing the presence of butyric acid, which cannot be neutralized by water. It is interesting to observe that in many cases heart-burn is not caused by acids at all, inasmuch as the fluid of the stomach is alkaline; in such cases relief is best obtained by acids. The burning sensation, which spreads upward, is sometimes a symptom of inflammation of the cardia, in which case there is a constant feeling of burning in the pit of the stomach.

The size of the stomach, in cases of round ulcer, is variable. If the ulcer is close to the pylorus, a contraction of the latter may give rise to a dilatation of the stomach. A frequent cause of dilatation is also found in catarrh, which relaxes the muscular fibres, and consequently renders the stomach distensible by gases.

The shape of the stomach is also frequently changed. When the ulcer is situated in the middle of the lesser curvature, the stomach may be converted into two sections, a cardiac and a pyloric, looking like an hour-glass.

The stomach is diminished in size, when the ulcer is extending and yet continually contracting. Constipation is the commonest of occurrences. But, on the other hand, the stomach may lose its power of contraction through catarrh of the pylorus, which gives rise to lientery—the discharge of undigested food in the fæces.

The nutrition is often but slightly affected, provided there is no hæmorrhage and cardialgia does not set in during the night. But when the cardialgia increases in severity, the digestive powers fail, and bleeding occurs, then the patients grow pale and thin, and sometimes acquire the cancerous aspect, which of course makes the diagnosis more difficult.

Most cases of ulcer rotundum ventriculi, like chronic maladies of the stomach in general, are combined with tuberculosis pulmonum and phthisis.

If the ulcer has lasted several months it may still heal; but when it has existed for years, and has become callous, when the stomach is already perforated, and is only prevented from further rupture by adhesion to the diaphragm, transverse colon, pancreas or liver, then healing is very difficult. The result of the ulcer is either a cicatrix, or a perforation and fatal peritonitis. Such a perforation may easily be recognized by percussion of the right hypochondrium; for we find that on the right the clear resonance of the lungs passes directly into that of the intestines, because the liver is pressed back by air which has entered the abdominal cavity, and hangs merely by the ligamentum suspensorium hepatis.

Death may occur either from excessive bleeding, or even without bleeding, from marasmus.

As to the origin of these ulcers, the first step is probably an inflammation, in consequence of which some of the arteries become blocked up; this gives rise to necrosis of a portion of tissue, which is attacked and digested by the gastric juice. As the occlusion of the arteries extends, the necrosis extends likewise.

In the matter of therapeutics, the treatment with sour milk is the chief point. For the cardialgia, give magistery of bismuth (subnitrate), with acetate of morphia, or if the patient is inclined to be constipated, with belladonna. Nitrate of silver (one-tenth grain) is also given in the form of a pill. For excessive vomiting, subcutaneous injections of morphia are the best remedy; or, if the morphia itself be the cause of vomiting, “pills” of ice, which have likewise a good influence upon the hæmatemesis through their effect in contracting the gastric bloodvessels. If peritonitis occurs, it is betrayed by the continuous pain. We should then resort without delay to local bloodletting, and cold applications (kalte umschläge) in the region of the stomach.

For heart-burn, bicarbonate of soda, chalk, magnesia, and conchæ preparatæ are given; when the last is used, the patients often have disagreeable sensations in the stomach, as the article is entirely composed of minute pointed fragments. (Dog's dung has been employed for the same purpose.) The magistery of bismuth has the best effect.

For tympanites ventriculi, the best remedy is friction, with æthereal oils in the region of the stomach. By this means the

stomach is relaxed, the cardia or the pylorus opens, and the gases are enabled to escape.

### CATTLE DISEASE.

MR. EDITOR:—At session of the Academy of Sciences of Paris, Jan. 11th, 1869, M. Bouley communicated to the Academy the results of experimental researches he had made last summer on a disease in cattle in Auvergne; through an official commission of which he was appointed president by the Minister of Agriculture, and M. A. Sanson secretary.

The disease has existed from time immemorial in the mountains of Cantal and Puy-de-Dôme, and the inhabitants call it *disease of the mountains*.

The Commission at once found that the disease was virulent, and transmissible by inoculation to the ox, the sheep, and the rabbit; and that the disease was none other than charbon, as Petit had shown towards the end of the last century.

The commission thought it proper to profit by the opportunity given them to the study of the question whether the virulence of charbonous blood depended exclusively upon the presence of bacterids. Their researches did not confirm the opinion of such dependence. The following were the results of their investigations:

1st, That blood taken from a charbonous animal can transmit charbon, when the presence of bacterids cannot be discovered by the microscope. 2d, That charbonous blood containing bacterids in large quantities loses its virulence by desiccation, and does not regain it by being liquified by water, although the bacterids remain perfectly visible. 3d, That the blood of rabbits dead in consequence of inoculation of charbon always contained bacterids, even when the liquid inoculated contained none; whilst amongst ruminants, the ox and sheep, dead from like inoculation and from the disease taken in the natural way, the presence of bacterids in the blood was not constant. Thus they are sometimes found and sometimes not; and when not found the virulence of the blood tried by inoculation was none the less active.

According to M. Sanson, and after original experimentation, the alteration undergone by charbonous blood is none other than a putrid fermentation; both the charbonous blood and the blood in which putrid fermentation has begun, having this common character, that in both the modified

albumen acquires the properties of a diastase, capable of converting starch into sugar. Both also have this other common characteristic, that when inoculated they will alike produce the same disease—charbon.

Mr. Bonley closed his communication by testifying to the good results derived from the internal and external administration of phenic acid.—(Translated from *Archives Gén. de Médecine*, Feb., 1869, p. 247.)

## Reports of Medical Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.  
CHARLES D. HOMANS, M.D., SECRETARY.

DEC. 14th.—*A Case of Imperforate Anus, with opening into the Vagina.* Reported by DR. S. L. SPRAGUE.

On the 14th of Aug. I attended Mrs. C. in confinement, who was delivered of a healthy girl, her third child. The child passed its fæces, the napkins were soiled, and nothing was seen unusual until the sixth day, when the grandmother who had the care of it noticed that the contents of the bowels came from the vagina, and that there was no anus. She informed me that the child was sadly deformed, and wished it would die.

I saw that the fæces passed by the vagina, but did not make a thorough examination until the next day, when in company with Dr. C. D. Homans I examined the child.

Touching the vagina caused straining by child, and it passed fæces in a fine stream through a small opening, at the edge of the vagina at the posterior commissure. This opening was of the size of a small probe, which was passed in and found to pass freely into a large dilated cavity, the rectum. The opening was in the posterior commissure of the vagina, where the integument joins it on the perinæum.

The fæces were discharged quite freely, and as the child appeared well and nursed well, it was thought best not to do anything immediately in the way of remedying the deformity.

The child continued well for some days, but in the course of a week I was called to it, as it was sick and refused to nurse. I found the abdomen swollen and tense, the small opening in the vulva not being sufficiently large for the discharge of the fæces. The perinæum was smooth, and no bulging, as is sometimes seen when the contents of the bowels are forced down by the straining

efforts of defæcation. I passed a probe through the opening and pressed down upon the perinæum, causing a prominence by the end of the probe nearer to where the anus should be, and then made an opening which gave free exit to the fæces. The child had great relief, it nursed well and grew. This opening gradually narrowed, the fæces did not pass freely, the bowels became swollen and hard, and the child's appetite failed. The mother felt very sad, and feared the child, if it lived, would be miserable in health and more miserable in mind if it ever lived to realize its situation, and she therefore wished the child would die, and rather opposed anything more being done. She was persuaded, however, to submit the child to another operation, and on the nineteenth day from the time of the first opening thus made, I passed a director through the opening in the vulva, bringing the end out at the other opening on the perinæum, and dividing the integument, brought the two openings into one large opening. The fæces discharged freely, and the child regained its appetite and health, and grew fat. The operation was performed on the 16th of September, three months since. The opening has not contracted, but easily admits the little finger. The fæces pass freely, and the child grows and is perfectly well.

Imperforate anus by a membrane which covers the anus is the most favorable kind to deal with, and the least serious in its results.

Imperforate anus with opening into the vagina is a very disagreeable defect of formation (malformation), but not necessarily fatal. If the opening is too small the infant will perish from impossibility of discharging its fæces; but if the opening is sufficiently large, the child lives, and its life is not shortened by it.

Cases are recorded of this variety, which are mentioned by Boyer.

"De Jussieu reports that he knew a girl 8 years of age who had the anus closed, and passed the fæces by the vulva.

"Benivenius says that a girl born with imperforate anus passed some days after birth faecal matter by the vulva, and that she lived with the infirmity to the age of 16 years, when she died in the most violent pains of colic.

"San Swieten knew a marriageable girl every way healthy, but with this deformity.

"Haesbart speaks of seeing a girl 20 years old who passed fæces by the vulva, the anus being imperforate. She enjoyed good health.

"One case especially interesting is report-

ed by Morgagni—the daughter of a Jew called Teutonicus. She came into the world without an anus, passed her fæces by the vagina, and lived to the age of an hundred years."

Dr. JACKSON said he had seen several such cases in infants; had also seen one in a pig. Dr. Mussey has reported a case in an adult.

Dr. HOOKER had seen two such cases; one child died at the age of one month of disease resulting from the malformation, the other is 3 or 4 years old and healthy.

## Bibliographical Notices.

---

*A Treatise on the Diseases of Infancy and Childhood.* By J. LEWIS SMITH, M.D., Curator to the Nursery and Child's Hospital, New York; Physician to the Infant's Hospital, Ward's Island, &c. Svo. Pp. 620. Philadelphia. 1869.

We have perused Dr. Smith's book with not a little satisfaction: it is indeed an excellent work; well and correctly written; thoroughly up to the modern ideas; concise, yet complete in its material. While we deprecate the present method of stringing words to words, after the fashion of our home and foreign brothers, with the seeming sole purpose of writing one's self into notice, we cannot help welcoming a work which will be worthy of reliance as a text book for medical students and younger physicians in their investigation of disease in children.

Dr. Smith offers us a general text book for the diseases of childhood; he takes occasion, however, in the early chapters to consider the child in its normal state, and gives practical and most excellent rules relating to the care of the mother in pregnancy, lactation, feeding, weaning, &c. In this portion and throughout the work his constant references to the medical journals of the last decade show that he is thoroughly conversant with the current literature of the subject, and, in our present age of progress, we certainly recognize in this the only satisfactory method of keeping pace with the most enlightened experience. We therefore feel that the work in question is well adapted to the practitioner who has not the time or opportunity to keep up with the ideas of the modern schools. The fact that the author makes reference to Dr. Ware and Dr. Jackson—men whom we all highly respect in this community—will help to give it good standing among us.

After considering the subjects above mentioned, and infantile diagnosis in general, the author proceeds to consider, in successive sections, diseases of the cerebro-spinal, respiratory, digestive and circulatory systems, zymotic diseases, and diseases of the skin. Dr. Smith's concise, yet searching description of each disease reminds us of the style of Gooch; while his practical and careful suggestions for treatment recall the instructions we received from Dr. Ware. We are especially struck with the articles on meningitis, eclampsia, croup, indigestion and scarlet fever. His treatment is simple in the extreme; mercury and the lancet—which our English friends, with the persistence characteristic of their race, are reluctantly giving up—are hardly mentioned; remedies which, as we look back at their former indiscriminate use, happily remind us of the palæozoic animals, "dying of an altered world."

We are glad to notice one point in the book before us. We think too little, we fear, in this age, of the future *permanent* benefit of our little patients; we fail to inquire, while we tide over the little sufferers in what seem to us temporary illnesses, what shall be life and health-giving remedies for their whole life-journey; we forget that "it is not merely the alternative between life and death, but between wholesome, happy, enjoyable life, and the innumerable forms of death in life, which an unhealthy or neglected childhood entails upon the innocent sufferers to the end of their days." Can we be censured, looking, as some of us have daily to do, on the piteous wrecks of childhood which are brought before us, for thinking the death of such children a desirable possibility? Though he does not expressly discuss this subject, we cannot fail to notice that the advice of Dr. Smith constantly looks to the future as well as the immediate good of the patient.

Every work, however, must have its objectionable points, and as honest critics we feel that we ought to speak of them. For instance, we object to the nomenclature of the disease which Dr. Smith calls "Internal convulsions." The term is a popular one, indeed; but, for that very reason, it should not be a professional one. It gives no idea of the locality of the trouble, and should be set aside as unscientific in the same class with debility, scrofula and other discarded terms. Almost any other of the terms applied to it in our text books we think preferable.

We do not wish to appear captious when we say that in many of our medical books of the present day we are constantly per-

plexed by the poverty of the indices; and Dr. Smith's work is not an exception. For instance, the title internal convulsions may be unknown to a practitioner who is accustomed to call the disease laryngismus stridulus, or spasm of the glottis, or thymic asthma, or something else. In Dr. Smith's work the disease is only entered as "convulsions, internal." Should not the author also give us cross references under half a dozen other letters and titles, and so render his work doubly valuable, as well as save the time and patience of his readers? We notice also that he makes no mention of umbilical hæmorrhage, a subject which we feel should not be omitted from a treatise on infantile disease, and which has been so thoroughly treated by a gentleman of our own city. On a few other points only do we feel compelled to differ from the author.

The book is very free from those crudities of judgment and practice and style which disfigure so much of our current professional literature; and we are glad to close, as we began, by welcoming a valuable book to the profession.

## Medical and Surgical Journal.

---

BOSTON: THURSDAY, MARCH 4, 1869.

---

### THE STATUS OF MEDICAL OFFICERS IN THE U. S. NAVY.

It is desirable, on grounds of national self-respect and *esprit de corps*, that our profession should be represented abroad by gentlemen of education and good attainments. The trans-Atlantic estimate of American medical men is of course based more or less on the qualifications of the surgeons of our ships of war, of which some are constantly in various European ports. To secure the continuance of a class of highly educated men as surgeons in the navy, it is requisite that there should be no falling off, relatively or absolutely, in the promotions for prolonged and meritorious services awarded to those officers. It is intimated, in a reliable document now before us, that there is a "prevalent disposition to seek more promising fields than the navy now offers to members of the medical profession." It is further stated that the "resignations of medical officers

are so numerous, and the number of candidates qualified to fill their places are so few that, according to the last annual report of the 'Chief of the Bureau of Medicine and Surgery,' there are no less than forty-eight (48) vacancies in the medical staff; and he expresses an opinion that this branch of the public service is threatened with *disintegration*; and that it can be averted only by effective Congressional action." Such legislation has been, and probably will be again solicited. It seems to us, therefore, highly fitting that medical men in civil life should be prepared to say a timely word in behalf of our brethren "who go down to the sea in ships," should be at least in possession of the facts, so as not to be obliged to confess ignorance of movements for the advantage of the naval surgeon, if consulted on the subject by any likely to influence legislation. And, it is reported to us by our friend Dr. S. F. Cones, of the Navy, that the medical officers of that branch of the public service earnestly desire the support and sympathy, and also, if possible, the coöperation of their professional brethren in civil positions, in their attempts to obtain a recognition of the value of their services during the late war.

Dr. Cones says, in a letter to us:—

"The medical corps simply asks, that their services should be rewarded as those of line officers have been; that the same rank relatively to the line that they had before the war should be restored to them; that in rank and position they should be the equals of the medical officers of the army and of other navies. No increase of pay or of numbers is asked for; but a change in the assignment of duty, which will enable the older surgeons to enjoy, on *shore stations*, their higher rank, and throw more of the sea service upon the younger men.

"It is hoped that these changes, if made, will prove an incentive to young men of education and ability to enter the corps."

As we understand the matter, the Surgeons of the Navy, by an order of August 31, 1846, ranked from above downward as Commander, Lieutenant, Master, Passed Midshipman, Midshipman, there being one "Line Grade" unattainable by medical officers—viz., that of Captain. But by an order of March 13th, 1863, the medical grades were made to range from Captain,

down through Commander, Lieut.-Commander, Lieutenant to Master, while instead of one "Line Grade" above them as before, there were constituted four such—viz., Admiral, Vice-Admiral, Rear-Admiral, Commodore. It is this relative *de-gradation* that it is sought to rectify. And as naval rank is not merely a name, but means position and personal comfort, particularly in advancing years, it seems to us that our *confrères* of the quarter-deck have a claim, additional to that already mentioned, upon our interest in their behalf.

The main features of the "proposed rank and assignment of service" sought for the Medical Staff of the U. S. Navy, are set forth in the three sections we quote below from a bill on which, or on one similar to which, Congress will be called to act. A bill asking for an increase of pay, we perceive by a *New York Medical Journal* has been defeated. A new bill, not providing for such increased pay, is now in question.

"SEC. 1st. *Be it enacted* by the Senate and House of Representatives of the United States of America, in Congress assembled: That on the passage of this Act, the President of the United States by and with the advice and consent of the Senate, shall appoint from the present Corps of Surgeons on the Active List of the Navy, a Chief of Bureau of Medicine and Surgery, who shall hold his office for the term of four years, and who shall be, *ex officio*, the ranking officer of the Medical Staff, and receive the same compensation for his services as the Chief of any other Bureau of the Navy Department.

"SEC. 2d. *And be it further enacted:* That the President of the United States shall, in like manner, appoint from the Surgeons on the Active List of the Navy in the order of their official seniority, twelve (12) Medical Director-Generals, each with the rank, pay and emoluments of a Commodore in the line of the Navy; eighteen (18) Medical Inspector-Generals, each with the rank, pay and emoluments of a Captain, who shall be employed only at Naval Hospitals and Laboratories, or as members of Examining and other Boards and Courts, and any other special duty on shore; twenty (20) Medical Directors, each with the rank, pay and emoluments of a Commander, to be employed at Navy Yards and Stations, and on board of Flag-ships, to direct and supervise all matters pertaining to the Medical De-

partment of the Navy Yard, Station, Squadron or Fleet to which they may be assigned for duty; and thirty (30) Surgeons, each with the rank, pay and emoluments of a Lieutenant-Commander, to be employed on board of first and second rate vessels of war, commissioned for sea-service, on Receiving Ships at Rendezvous and Barracks, and as Executive Officers of Hospitals, or on such special duties as the Secretary of the Navy may direct.

"SEC. 3d. *And be it further enacted:* That the President shall, in like manner, and in accordance with existing laws, appoint one hundred and twenty (120) Assistant Surgeons, each with the rank, pay and emoluments of a Master, including the Assistant Surgeons now in the Navy. *Provided:* that Assistant Surgeons of three years' service, who have been found qualified for promotion by a competent Board of Examiners, shall have the rank, pay and emoluments of Lieutenants; and further that all Assistant Surgeons shall be employed wherever the Secretary of the Navy may direct. *And provided further,* that no Medical Officer shall, in virtue of his rank, exercise command or authority in the Line of the Navy, or in any Staff Corps belonging thereto, except in the Medical Staff, and over those placed under the control of the Medical Department of the Naval Service."

The bill from which the above sections are taken is accompanied by the following petition:—

*"To the Honorable the Senate and House of Representatives of the United States, in Congress assembled:—*

"The Medical Officers of the U. S. Navy respectfully come before your Honorable Bodies, asking a reasonable and just rank in the military service to which they belong—a rank correspondent to their duties and responsibilities, and, in some degree, approaching that conferred upon the same class of officers in the other military services of the world.

"Our naval service ought not to be second in importance, character and dignity to any, and the influence of its future in the destinies of the world must be evident to all. The equality of its dignity has been partially, and but partially, asserted by the establishment of the highest grades of rank for the line of the navy. To permit the continuance for its medical corps of positions inferior to those of the same corps in other navies, we respectfully submit, may seem to confess an inferiority, either of our

whole service, or of the officers composing its medical corps.

"Prior to the establishment of the existing grades of the 'Line,' the highest Naval rank was that of 'captain,' and the medical corps reached that of 'commander,' the next grade below. Now, since the grades of admiral, vice-admiral, rear-admiral and commodore have been added to the service, we attain to that of captain, leaving us to the fifth in the military gradation, instead of the second, as we were before passing through the risks and labors it was our duty to encounter in the late war.

"Similar risks and toils, and no greater, deservedly brought to our brethren of the line honorable distinctions; we rejoice in their reward and respect the justice which bestowed it. To the medical corps of the army also were promptly given those distinctions which every member of a military service learns to prize; and we waited in the patient hope that a record of honorable and faithful service, not behind any, would bring to the naval medical corps their share of honorable acknowledgment, and not leave them a marked exception amid the general recognition.

"No such acknowledgment has yet come. The war left us, as has been shown, relatively to the line, four degrees lower in rank. Yet, whether as heads of our department in squadrons, or acting in detail, no charge of failure or of unfaithful performance of our duties has been, or can be brought against us.

"It should not take from the value of any duties, that they are, from their nature, most efficiently, when most quietly and unobtrusively performed: and are never brought dramatically before the public eye, unless, unhappily, want of skill or fidelity results in misfortune, destruction and disgrace.

"We ask an addition of one grade for the senior officers of our corps. The table\* appended shows that in the Navies of Great Britain, France, and Russia, officers of the medical corps reach the rank of vice-admiral; and, in the navy of Austria, that of rear-admiral. It is evident that such experienced military powers, relying chiefly as they do for existence on their armed organization, would not confer such honors upon a staff, except from the conviction of necessity; especially as, under the artificial class distinctions of those Governments—Line and Staff Officers are, as a rule, taken

\* Omitted here.—ED.

from those who in civil life occupy different grades in their social system.

"With us no such artificial distinctions are recognized, and under our enlightened institutions, both line and staff are taken from all classes of the Republic, the humblest ranks, and often the same families, being represented in both divisions of the service. Such being the truth, there can be, we hope, no one so ignorant of the institutions of his country as to imagine that any honors, the reward of public service, are the special right of any privileged class.

"As then our Republic permits no class prejudice or presumption to which the just claims of any of its servants shall be sacrificed, it may be asked, why should these honors and distinctions be withheld the medical corps of the United States Navy, which military discretion and prudence have exacted for 'Line' and 'Staff' from military powers, under which, class privileges, unknown to us, are recognized?

"In the above recited facts is found the best testimony of military experience for the necessity of a definite and a high medical staff rank in the interests of military subordination, and therefore we are spared the need of troubling your Honorable bodies with the ample argument upon a subject so conclusively settled.

"We present this memorial to your Honorable Bodies the more confident of its favorable consideration, because what we ask takes nothing from the rights and privileges of any—conflicts with no subordination, but rather sustains it; and although we make our petition upon its own merits, we have the satisfaction of knowing, we ask nothing which has not been sanctioned by some of the most illustrious of our brethren of the line. Nor can we think that among the intelligent and liberal minded of our service there are any so doubtful of their own honors, as to believe they are only valuable by contrast with those still neglected but allied corps, the members of which, in our service, with the same honorable motives and with equal sacrifices and no less zeal, are laboring for the honor and glory of our common country.

"All of which is respectfully submitted."

The petition was signed by a host of eminent names.

**ICTERUS AND PNEUMONIA.**—With reference to the clinical remarks of Oppolzer, on Icterus and Pneumonia (translated in our issue of Feb. 18), Dr. J. B. S. Jackson makes

the following comments in a note he has had the kindness to send us.

"I have met with quite a number of cases of pneumonia complicated with icterus in former years, and feel very confident that in all of them the disease was upon the right side, and that there was severe inflammation of the pleura about the base of the lung. How it can be explained if it be a fact I know not; but I always supposed that the function of the liver was disturbed in such cases, and in some way by the inflammation that was going on in its immediate neighborhood. The diaphragm only separates this organ from the seat of the disease; and we know that in severe cases of pleurisy not merely the pericardium, but the peritoneum sometimes becomes inflamed, though I do not think that peritoneal inflammation about the liver would be by any means essential to the icterus. As to the gastro-duodenal catarrh that Oppolzer speaks of, I do not remember anything of the kind in the cases that I have seen, and I cannot think that I should have overlooked it if it existed."

In consequence of these remarks of Dr. Jackson, a further examination of Oppolzer's lecture was made at our request, and the following extract was furnished us.

"People have tried to make the matter a very simple one, by assuming that the diaphragm, in pneumonia, cannot move because its pleural investment is inflamed together with the lung. In consequence of this, the pressure and the motion which the liver undergoes, and which are supposed to be indispensable in the process of secreting bile, are removed. If this were the fact, then icterus ought to occur only when the right lower lobe is infiltrated in pneumonia; while in point of fact icterus may appear during pneumonia of the right upper lobe, or of the left lung. The impeded motion of the diaphragm, therefore, is not the cause of icterus in pneumonia."

**NOTE UPON THE DIAGNOSTIC EXPEDIENTS OF DR. J. MARION SIMS.**—We take pleasure in laying before our readers the following note from a valued medical friend. We can assure them that were the name of the writer made known, they would recognize in him one of the most respected and trusted of the profession:

MR. EDITOR:—I had intended to send you a notice of the article of Dr. J. Marion Sims, of New York City, published in the

*New York Medical Journal* for January, 1869, and later issued in pamphlet form, its title running thus: "On the Microscope in the Diagnosis and Treatment of Sterility;" but your comments in last week's *JOURNAL*, together with the presentation of the main points insisted upon by Dr. Sims, render any detailed remarks, in the way of review, unnecessary. Perhaps you will allow me, however, to express my own impressions of the author and my ideas as to the particular subject he brings to the notice of the profession. It has been my good fortune to become acquainted with Dr. Sims, and I have, on several occasions, derived great gratification and no little information from conversations with him upon medical topics—especially upon those relating to his specialty, and several times respecting the highly important subject discussed in the paper whose title has already been given.

With reference to Dr. Sims as a physician and surgeon, there is, I conclude, but one opinion. He is recognized as a judicious, careful and most ingenious adviser and inventor; he is remarkable for quick diagnostic insight, gentle and yet effective manipulation, honesty of purpose, and a steady pursuit of investigations into "the Science and the Art" of Medicine which do him honor, and from which he is reaping both fame and fortune. Almost any amount of abuse and detraction has been lavished upon Dr. Sims, in times past; but it is probable that the vials are empty now—or, if anything more should be forthcoming, it will do him no harm. To those who really know him, he seems singularly simple, earnest of purpose and upright in intention, combining originality of design with readiness in planning modes or appliances of treatment. I have had opportunities of judging, and can testify to his delicate and modest manner of conducting operations and examinations—a manner, and an evident sincerity, which shut out at once all suspicion of coarse intent or purient imagination.

So much for the man and the physician; now for the scientific points at issue, or under review.

There are those—even in these days of abortion-procuring, and aversion to, or shirking of, the maternal lot—the maternal privilege—who consider *sterility* an evil. It is needless to insist upon the evident fact, that, in too many cases, it becomes a genuine calamity. Whoever, therefore, helps to render the barren woman fertile, is a benefactor, in the best sense. Oftentimes he may be the means of rescuing a family name from extinction. Indeed, there arise neces-

sities in society, which sweep away at once the "prejudices" which not only you, Mr. Editor, but many others—I may include myself—very naturally have cherished in this connection. You may see modest and delicate women, actuated by motives which no suspicion can impugn and no sneers dispel, go bravely through an ordeal confessedly most trying, and rewarded, too, in many instances, for their courage and their good faith! "*Honi soit qui mal y pense.*" I suppose you, Mr. Editor, from the just and kindly tone you adopt towards the author of the article in question, believe in his truthfulness and in his honor? This being so, if his reports of the successful treatment of sterility by rectifying the perverted uterine secretions when it is ascertained, by the microscope, that they destroy the spermatozoa, be reliable, is not this method of procedure not only admissible, but ought it not to be hailed by the profession, and by all the right-minded of the community, as a *scientific triumph* in obstetric medicine and surgery, and its originator be honored and respected accordingly? "*Palmas qui meruit ferat.*"

\*\*\*

Boston, Feb. 19, 1869.

THE NORMAL DIAPASON.—In order to be rid of our importunate demands that he would give us something on the physiology or pathology of the voice, a medical friend has sent us the following valuable communication. In it the Doctor anxiously inquires where the modern impositions on the vocal organs will stop? Our answer is—at the limits of the *vox humana*!

MR. EDITOR,—Apollo being the god and guardian of medicine as well as of music, I make no apology for offering a few observations on a subject which is just now agitating the minds of our English brethren, viz., the modern orchestral pitch.

It is well known by all who have examined into this matter that within the last hundred years the pitch has gradually risen nearly, if not quite, a whole tone of the musical scale. Some of the original scores of Gluck and of Handel have become therefore almost impossible for the ordinary vocalists of the present day. Within the last quarter of a century this upward tendency has increased in accelerated ratio. The inquiry naturally arises when and where is it to stop; and what is to be the effect if such disposition be not speedily arrested, or indeed turned back to its original starting point?

These are questions possessing not merely

an æsthetic or scientific interest. They are important, likewise, in a medical and surgical point of view, and their proper understanding will have a bearing upon the treatment of the various diseases of the vocal organs, which the medical man is now so much oftener than formerly called upon to consider.

It cannot be denied that in New England especially we are fast becoming a musical people. Every city and large town has its choral society, where the young men and maidens assemble to practise the music of a half century ago in the conventional pitch of the present day, and without any reference to the laws of vocal physiology. Can we wonder, when such strained and difficult vocalism as that contained in the oratorios of Mendelssohn and the choral symphony of Beethoven is attempted by hundreds and thousands of singers in this unnatural pitch, that broken-down voices and laryngeal diseases are the result?

The French were the first to appreciate the necessity of an immediate and radical change. On the 17th of July, 1858, a commission was appointed to investigate the subject and recommend what was best to be done. This commission included the names of such men as Halevy, Auber, Berlioz, Meyerbeer, Rossini and David. Views and opinions were solicited from England, Germany, Belgium, Holland, Italy and America. The result was the establishment by government decree of a new pitch, the standard of which for treble C should be 522 vibrations in a second. This was henceforth to be regarded as the normal diapason of France, and was lower by nearly half a tone than the standard to which the orchestral pitch had then been strained. This decree was promulgated on the 16th of February, 1859, and came into force in Paris and throughout France on the 1st of July in the same year.

Some of the leading nations of Europe adopted the new standard at once, and it has since been gradually extending over the continent.

England, with her national unwillingness to assimilate anything of French origin, has till now doggedly clung to the high pitch. And we in America have as pertinaciously seconded our brother Bull.

Quite recently, however, the subject has attracted the attention of medical men in Great Britain. Says Dr. Stone, one of the physicians to the Royal Society of Musicians in London, "My own experience, founded on many hundred cases observed at the Brompton Hospital, leads me to consider singing as now practised more injuri-

ous to the lungs and larynx than the moderate and well-guided practice of wind instruments. This cannot possibly be a necessary evil. I, for one, believe it in a great measure due to high pitch, and to neglect of physiological precautions. The public, indeed, sees little of what results; but the medical man has often to watch the premature breaking up of a fine voice and perhaps a healthy constitution, both of which, under careful management, might have been preserved."

The time has arrived when we, too, must succumb. The human larynx deserves at least as tender regard in the rude climate of New England as in France, Germany, and Italy. The contest is between the human voice, that most precious and delicate of all instruments, and its orchestral counterparts, which are, at best, its clumsy imitators. It is the duty of the medical profession to aid in a movement so essential, at the same time, to the interests of humanity and of true art. C<sub>7</sub>, M.D.

AMERICAN MEDICAL ASSOCIATION. — The twentieth annual session will be held in New Orleans, La., May 4th, 1869, at 11 A.M.

The following committees are expected to report:—On Diseases of the Cornea, Dr. Jos. S. Hildreth, Illinois, Chairman. On cultivation of the Cinchona Tree, Dr. Lemuel J. Deal, Pennsylvania, Chairman. On Excision of Joints for Injuries, Dr. J. B. Reed, Georgia, Chairman. On Alcohol and its Relations to Medicine, Dr. John Bell, Pennsylvania, Chairman. On the Cryptogamic Origin of Disease with special reference to recent microscopic investigations on that subject, Dr. Edward Curtis, U.S.A., Chairman. On Operations for Hare-lip, Dr. A. Hammer, Missouri, Chairman. On Clinical Thermometry in Diphtheria, Dr. Jos. G. Richardson, New York, Chairman. On Prophylactics in Zymotic Diseases, Dr. Nelson L. North, New York, Chairman. On Inebriate Asylums, Dr. C. H. Nichols, D. C., Chairman. On the Influence of the Pneumogastric Nerve on Spasmodic and Rhythmical Movements of the Lungs, Dr. Thomas Antisell, D. C., Chairman. To Examine into the Present Plan of Organization and Management of the United States Marine Hospitals, Dr. D. W. Bliss, D. C., Chairman. On the Utilization of Sewerage, Dr. Stephen Smith, New York, Chairman. On the Influence of Quarantine in Preventing the Introduction of Disease into the ports of the United States, Dr. Elisha

Harris, N. Y., Chairman. On Nurse Training Institutions, Dr. Samuel D. Gross, Pennsylvania, Chairman. On Commissioners to aid in Trials involving Scientific Testimony, Dr. John Ordronaux, N. Y., Chairman. On Annual Medical Register, Dr. John H. Packard, Pennsylvania, Chairman. On Devising a Plan for the Relief of Widows and Orphans of Medical Men, Dr. John H. Griscom, N. Y., Chairman. On Veterinary Colleges, Dr. Thomas Antisell, D. C., Chairman. On Specialties in Medicine, and the Propriety of Specialists Advertising, Dr. E. Lloyd Howard, Maryland, Chairman. On Library of American Medical Works, Dr. J. M. Toner, D. C., Chairman. On Vaccination, Dr. Henry A. Martin, Massachusetts, Chairman. On the Decomposition of Urea in Uræmic Poisoning, Dr. H. R. Noel, Maryland, Chairman. On the best method of treatment for the different forms of Cleft Palate, Dr. J. R. Whitehead, New York, Chairman. On Rank of Medical Men in the Navy, Dr. N. S. Davis, Illinois, Chairman. On Medical Ethics, Dr. D. Francis Condie, Pennsylvania, Chairman. On American Medical Necrology, Dr. C. C. Cox, Maryland, Chairman. On Medical Education, Dr. J. C. Reeve, Ohio, Chairman. On Medical Literature, Dr. E. Warren, Maryland, Chairman. On Prize Essays, Dr. S. M. Bemiss, Louisiana, Chairman.

On the Climatology and Epidemics of—Maine, Dr. J. C. Weston. New Hampshire, Dr. P. A. Stackpole. Vermont, Dr. Henry Janes. Massachusetts, Dr. H. I. Bowditch. Rhode Island, Dr. C. W. Parsons. Connecticut, Dr. E. K. Hunt. New York, Dr. W. F. Thoms. New Jersey, Dr. Ezra M. Hunt. Pennsylvania, Dr. D. F. Condie. Maryland, Dr. O. S. Mahon. Georgia, Dr. Juriah Harriss. Missouri, Dr. Geo. Engelman. Alabama, Dr. R. F. Michel. Texas, Dr. T. J. Heard. Illinois, Dr. R. C. Hamil. Indiana, Dr. J. F. Hibberd. District of Columbia, Dr. T. Antisell. Iowa, Dr. J. C. Hughes. Michigan, Dr. Abm. Sager. Ohio, Dr. E. L. Neal. California, Dr. F. W. Hatch. Tennessee, Dr. B. W. Avent. West Virginia, Dr. E. A. Hildreth. Minnesota, Dr. Samuel Willey. Virginia, Dr. W. O. Owen. Delaware, Dr. L. B. Bush. Arkansas, Dr. G. W. Lawrence. Mississippi, Dr. — Compton. Louisiana, Dr. L. T. Pimm.

Secretaries of all medical organizations are requested to forward lists of their Delegates as soon as elected, to the Permanent Secretary.

Any respectable physician who may desire to attend, but cannot do so as a dele-

gate, may be made a *member by invitation*, upon the recommendation of the Committee of Arrangements. W. B. ATKINSON.

WOUNDS OF JOINTS TREATED ON THE ANTISEPTIC METHOD BY CARBOLIC ACID.—Case I.—*Compound Comminuted Fracture, with Wound, of the Elbow-joint—Fracture of the Leg—Recovery.*—Patrick K., aged 40, a plasterer, fell from a scaffold of no great height, and was admitted into the Belfast General Hospital, under the care of Dr. William MacCormac, on July 31, 1868. Has been very intemperate, and in 1851 was partially paralyzed on the left side. On examination, the right leg was found to be fractured at the junction of its lower and middle thirds, and the soft parts around were much contused. Just above the inner condyle of the left humerus is a wound through which the finger might be easily passed through the joint to the opposite side of the limb. The lower end of the humerus was much comminuted, and a considerable piece of bone, a portion of the internal condyloid ridge, lay partially detached in the wound.

Dr. MacCormac was strongly urged to attempt excision of the elbow-joint, and to resort to amputation in case the extent of the injury should appear too severe to warrant such a procedure. The patient, however, refused to submit to operative interference. The wound was therefore dressed with lint soaked in carbolic oil, and the limb was placed upon an angular splint. Some oozing of blood took place, which coagulated upon the dressings. These were daily soaked in fresh oil, but were not disturbed until August 8, nine days after the injury. The patient complained of no suffering from the arm, and there was no local inflammation. The leg was put up on an outside splint, and, in consequence of the extensive bruising of the soft parts, proved more troublesome than the arm. When the dressings were removed from the wound a small quantity of matter was seen, below which healthy granulation appeared to fill-up the cavity. Carbolic lotion was now used in place of the oily dressing, and the wound continued to do well, the patient being reported convalescent six weeks after his admission.

When he left the Hospital he had regained very considerable power of extension and flexion of the affected joint, and retained the movements of pronation and supination.

CASE II.—*Compound Fracture of the Patella, with Wound of the Knee-joint—Recov-*

ery.—B., aged 45, of intemperate habits, fell whilst drunk on the edge of the foot-path, and was admitted on July 12, 1868, into the Hospital with an extensive contused wound,\* six inches long, stretching from one condyle of the femur across the front of the knee-joint to the other; the patella was fractured transversely, the tendon of the quadriceps extensor was torn, and the knee-joint was laid open, the articulating surfaces of the femur appearing through the wound. The limb was placed on a straight splint, and the wound was carefully cleansed and washed with carbolic oil, and then covered with lint soaked in the same. The circulation through the femoral artery was controlled by a tourniquet, and ice applied around the joint. On the following day the parts were somewhat swollen; the patient suffered some pain; pulse 142; tongue furred. These symptoms, however, gradually subsided, and five days later the pulse was only 100, the tongue was cleaner, and the swelling diminished. A slight amount of sloughing took place around the edge of the wound, but this was shortly followed by healthy granulation. Bony union took place between the fragments of the patella, and no ankylosis of the knee-joint occurred. The patient was discharged cured on September 28, and was then able to flex the limb at an angle of fifteen or twenty degrees.

CASE III.—*Lacerated Wound of the Wrist-joint—Recovery.*—A lad of 15 had his hand caught in a fluting machine in a linen mill. On admission into the Hospital a wound opening the wrist-joint was found to extend from the palm round the base of the thumb as far as the metacarpal bone of the index finger; the soft parts had been torn away, the trapezius and trapezoid were both injured, the scaphoid displaced backwards, and the joints of the second row of the carpus were laid open. The wound was dressed with carbolic oil, and a splint applied to the palm and forearm. Very little inflammatory action and suppuration occurred, and the wound healed rapidly, so that in a fortnight there was only a superficial granulating wound at the seat of injury. In five weeks the boy left the Hospital with only some stiffness of the wrist-joint and impaired movement in the thumb.

In the "Remarks" on these cases it is said, "It must, however, be borne in mind that similar results were sometimes obtained before carbolic acid was thought of, and therefore we cannot consider that this is necessarily an essential element in these cases; but it will probably be admitted

that the occurrence of three such cases at one time, and the uniformly satisfactory results obtained in all of them, would indicate something more than a mere coincidence.—*London Medical Times and Gazette.*

LIMITATION OF BIRTHS IN FRANCE.—Amongst Catholics, it is well known that contrivances for rendering married life childless are sedulously denounced by the clergy in the privacy of confession. But it is a great mistake to suppose that creed has any more influence on the prevalence of the customs in question than race has; for we know on indisputable authority that the Protestant pastors of the half-German Alsace preach openly on the matter, and that in spite of them the women express their determination to bear no more than two children. The effect of such customs on the health of the weaker sex has never yet been fully stated. As for national prosperity, it is quite true that a redundant population has its evils. There is the wretchedness arising from want of occupation, and if this be relieved by emigration, it may be said that every parent state may have to fight for its colonies first, and to fight against them afterwards. The history of the English Possessions in North America in the last century is illustrative enough of this. On the other hand, it must be conceded that all wars are not voluntary, and all are not the effect of a restless population unable to keep within its own borders. It is conceivable that the French of the twentieth century might find themselves menaced by invading hosts from the North and East, whom a population artificially limited, and looking to comfortable existence in France as their *summum bonum*, might find it difficult to resist.

We will only point out one duty which we think is overlooked by our neighbors. Man has relations to the Kosmos, and a debt to posterity. . . . It is not a redundant, but an ill-educated, ill-governed, selfish population that is to be feared. There is plenty of employment in England if the "hands" would but stoop to accept it. "Increase and multiply, fill the earth and subdue it." "Happy is the man who hath his quiver full; he shall not be afraid to meet his enemies." Such we hold to be sounder maxims of social economy than those which are acted on by the French democrat.—*Ibid.*

PROF. J. VILLE has discovered that the waters of certain lakes in Tuscany contain a large proportion of sulphate of ammonia.

## Medical Miscellany.

THE Medical Faculty of Harvard University gave a levee at the Revere House on Wednesday evening of last week, to the medical class of the session now just completed.

Among the specially invited guests we noticed Dr. McLaren, U. S. Army Medical Director of this District, His Honor Mayor Shurtleff (M.D.), and Dr. C. G. Putnam.

The elegant reception rooms of the Revere House were thronged by a body of young men of promising appearance. At nine o'clock the doors of the operating room were thrown open, where the function of the gustatory nerve was finely demonstrated, the preparations being excellent, and the supply of subjects ample.

**CITY HOSPITAL APPOINTMENTS.**—At the *con-cours* for the position of House Officers for the ensuing year, held Feb. 19th ult., the following gentlemen received the appointments.

Chas. F. Folsom—Senior House-Physician.  
Geo. B. Stevens—Senior House-Surgeon.  
Chas. B. Brigham—Second House-Surgeon.  
C. B. Shute—Junior House-Physician.  
N. P. Quint—Third House-Surgeon.  
Wm. F. Clarke—Ophthalmic Interne.  
A. Prondfoot—Ophthalmic Externe.

**A CRITICISM.**—A friend has spoken of the quotation from the *British Medical Journal* in our last issue, as though it were "nonsense in heavy-sounding words." How could he?

As will be seen by a notice in the advertising columns, the Commencement of the Medical Department of Harvard University will take place on Wednesday next. Our issue of next Thursday goes to press on Tuesday. Therefore the notice of the commencement cannot appear till the week following.

**ATTENTION** is called to the meeting of the Censors of the Suffolk District Medical Society advertised in this number.

THOSE intending to join the steamboat excursion of the American Medical Association to New Orleans, should send their names to Dr. Wm. B. Atkinson, 1400 Pine St., Philadelphia. Unless enough names are received the excursion will be given up.

THE following are the officers of the Butler Hospital for the Insane, Providence, R. I.:—John Carter Brown, President. Edward King, William Butler Duncan, Vice Presidents. Trustees, Amos D. Smith, Jabez C. Knight, John Kingsbury, Rufus Waterman, William Sprague, James T. Rhodes, Royal C. Taft, Tully D. Bowen, Amos C. Barstow, David Duncan. Moses B. I. Goddard, Treasurer. Robert H. Ives, Secretary. Joseph Mauran, M.D., G. L. Collins, M.D., J. W. C. Ely, M.D., Board of Consultation. John W. Sawyer, M.D., Superintendent and Physician. Samuel Worcester, M.D., Assistant Physician. Mrs. Sarah D. Lovett, Matron.

**RESIGNATION OF THE OFFICERS OF THE BOARD OF HEALTH IN NEW YORK.**—The one and only

apparent reason why these gentlemen resigned, was an attempt on the part of the Board to degrade their positions, assign them to unprofessional and undignified duties, and make use of them for political purposes. Similar attempts have been made from time to time, ever since the organization of the Board, but never, until recently, were there a sufficient number of men upon it of a character to sanction such action. That it is now so is much to be deplored. With few exceptions, the business of the Board of Health has, up to the present time, been conducted thoroughly, quietly, and in a manner eminently deserving the approbation of the medical profession. Its officers have been men thoroughly in sympathy with the profession, bound up in the same interests, and taking part, so far as the faithful discharge of their official duties permitted, in the same pursuits.—*N. Y. Medical Record.*

## MEDICAL DIARY OF THE WEEK.

MONDAY, 9, A.M., Massachusetts General Hospital, Med. Clinic. 9, A.M., City Hospital, Ophthalmic Clinic.  
TUESDAY, 9, A.M., City Hospital, Medical Clinic; 10, A.M., Surgical Lecture. 9 to 11, A.M., Boston Dispensary. 10-11, A.M., Massachusetts Eye and Ear Infirmary.  
WEDNESDAY, 10, A.M., Massachusetts General Hospital, Surgical Visit. 11 A.M., OPERATIONS.  
FRIDAY, 9, A.M., City Hospital, Ophthalmic Clinic; 10, A.M., Surgical Visit; 11, A.M., OPERATIONS. 9 to 11, A.M., Boston Dispensary.  
SATURDAY, 10, A.M., Massachusetts General Hospital Surgical Visit; 11, A.M., OPERATIONS.

**ERRATA.**—In last week's issue, page 70, in the extract from the *Dublin Medical Press and Circular*, for "he found," "he could pass a probe," read *there was found, a probe could be passed.* On page 72, 2d column, the paragraph headed "Carbonate of Lime in Pertussis," should read "*Carbolate of Lime in Pertussis.*"

**TO CORRESPONDENTS.**—The following communication has been received:—On Hay Fever, or Rose Cold; Translation of a paper by Gueneau de Mussy in *Gazette des Hôpitaux.*

**PAMPHLETS RECEIVED.**—Operation of Vesico-vaginal Fistula without the Aid of Assistants; with a view of the relative merits of the Clamp, Interrupted, Silver and Button Sutures. By Nathan Bozenian, M.D., New York.—Pathological Phenomena Generalized. By H. Backus, Montevallo, Alabama.

**DIED.**—At Auburndale, Feb. 25th, Dr. Edward A. Kittredge, 58 years, 7 months.—At North Haverhill, N. H., Feb. 17th, Dr. Henry B. Leonard, aged 51 years, 7 months, 9 days.—At Chicago, Ill., Feb. 3d, Dr. Elijah D. Harmon, of Bennington, Vt., aged 86 years.

**DEATHS IN BOSTON** for the week ending Saturday noon, February 27th, 99. Males, 50—Females, 49.—Abscess, 2—accident, 4—aneurism, 1—apoplexy, 2—asthma, 1—disease of the brain, 3—bronchitis, 3—burns, 1—cancer, 2—consumption, 13—convulsions, 2—croup, 7—debility, 4—diphtheria, 3—dropsy of the brain, 1—dyspepsia, 2—erysipelas, 2—scarlet fever, 13—typhoid fever, 1—disease of the heart, 3—hernia, 1—disease of the kidneys, 1—inflammation of the lungs, 9—old age, 7—paralysis, 1—peritonitis, 1—premature birth, 2—puerperal disease, 2—pyæmia, 1—syphilis, 1—whooping cough, 1—unknown, 2.

Under 5 years of age, 43—between 5 and 20 years, 7—between 20 and 40 years, 16—between 40 and 60 years, 15—above 60 years, 18. Born in the United States, 66—Ireland, 24—other places, 9.

ATROPINE; ITS PHYSIOLOGICAL ACTION,  
AND ITS USE IN TETANUS.

By ROBERT AMORY, M.D.

HAVING had an opportunity of trying two well-known and violent poisons in some cases of tetanus, I thought it might be interesting to publish some account of the effects of these remedies, and must ask for a brief space in your Journal.

Two forms of tetanus are recognized, the idiopathic and traumatic; names which indicate their supposed origin, but which reveal our ignorance of the pathological conditions under which they may occur. Tetanus may follow a slight injury, or some more serious wound. Dr. Dewees, in the *Medical Gazette*, considers\* "that in idiopathic tetanus a very frequent first step is sudden arrest of violent perspiration; and that certain reflexive acts may be thrown upon some disordered or impressible cerebro-spinal centre, causing convulsive muscular manifestations;" and goes on to show "how these repressed excreta act specifically, abrogating or over-exciting the nervous functions, thus producing all sorts of incurrent disorders." If this be so, the same effects which cause the disease, unless modified by some remedial or restraining action, tend to increase its manifestations. In accordance with these principles veterinary surgeons try by tremendous doses of aloes and other purgatives to relieve the system of excreta, and allow the animal to recover. Sometimes this treatment meets with success, especially in the form called idiopathic, but, generally, the prognosis is made (and correctly) that the animal will die.

The animals generally die from asphyxia or exhaustion, and in frightful convulsions. It would seem from what is known of the pathological condition produced by tetanus, that the sympathetic nervous system is in

an abnormal state, that of continued excitability, in which there is spasmodic contraction of the capillaries as well as of the voluntary and involuntary muscular system.

The pathological investigations made after death from tetanus, throw but little light upon our knowledge of the disease. The results are very often contradictory or doubtful, and have often been explained by a reference to the position of the body examined, in which extravasated blood was shown to gravitate towards certain points.

Chloroform has a restraining influence upon the tetanic spasms, but they recur as soon as the inhalation ceases. Before speaking of Belladonna as a remedy, I should like to notice some of its physiological effects.

Atropine seems to be poisonous to all animals, provided it is received and retained in a sufficient quantity in the blood. Herbivorous animals appear to eliminate the poison very rapidly, and both belladonna and atropine, in doses sufficient to kill several men, have been borne by goats, rabbits, guinea pigs and sparrows, with no inconvenient symptoms beyond dilatation of the pupil and diarrhoea. In carnivorous animals, however, its poisonous effects are very manifest, even in minute doses. Two milligrammes ( $\frac{1}{36}$  of a grain) produce cerebral trouble and serious accidents in man. If, however, fatal poisoning by this drug occurs, it follows very soon after its administration, as the drug is very rapidly eliminated.

Slight doses accelerate the capillary circulation, reducing the calibre of the arterioles, to 1-3 or 1-2 (by micrometer) their normal size. This retraction of the blood-vessels is not uniform, but the walls of the arterioles become unevenly contracted in undulations.\* The diminution of calibre coincides with the acceleration of the circulation. Hayden† has concluded that this constriction is due to reflex action. For in cutting the integument of a frog's leg this same phenomenon occurs. The sciatic

\* Dec., 1862.

\* Wharton Jones, Med. Times and Gazette, 1857, p. 27.  
† Dublin Quarterly Jour. of Med. Science, Aug. 1862.

nerve contains some filaments of the sympathetic system also, so that we must not be surprised to find that the constriction produced by this operation is not as marked as that caused by the atropine. Hayden also notices the coincidence of accelerated circulation *with* the constriction. These effects on the circulation continue but a short time, and the arteries soon return to their primitive condition. The veins do not diminish in volume.

If, however, the dose be larger, the circulation slackens, and then completely stops. All the vessels are gorged with stagnant blood, a perfect hyperæmia results. This stasis commences in the venules and then ensues in the capillaries and arterioles. The blood stops in the artery only after the stasis occurs in the capillaries. These same effects occur, also, when the drug is applied to a portion of the circulation under microscopical observation.

The effect of the smaller dose is exciting, and its local application seems painful to the frog. In the denuded skin of man the pain is compared to that produced by a hot iron.

In larger doses it seems to paralyze the vaso-motor system; the flesh has a blood-red appearance, and with the microscope is seen to be in a state of hyperæmia. These peculiarities have been also observed in the mesentery of the rat, and in the ear of rabbits. Meuriot\* would then consider atropine as a vasculo-cardiac agent, and to his memoir, mainly, I am indebted for much of my knowledge of its action.

With regard to its qualities as an anæsthetic, Meuriot affirms that superficial neuralgia derives much benefit from atropine if applied topically. In small doses, however, exhibited by the stomach, I know of three cases of nervous headache which have been often and decidedly relieved by belladonna. In fact, homœopaths prescribe their sugar-plums of belladonna for all headaches of this kind, and their success is notorious.

The inconvenience of hypodermic applications of atropine is the severe pain caused by its contact; which, as I have already said, has been compared to that caused by a hot iron. This may persist for two or three days, and is supposed to be owing to the trouble in the capillary circulation of the skin. We see the same conditions in severe chillblains. This drug never destroys sensibility, but may induce analgesia.

Nerves in contact with atropine preserve

their excitability, and the contact of the electrodes causes contractions, reflex movements, and cries.

In frogs peripheric sensibility is diminished, but this is not the case with other animals experimented upon.

Its action upon the spinal cord as compared with strychnine and bromide of potassium is peculiar.

Strychnine produces an exaltation or exaggeration of the excito-motory functions dependent upon this central organ. The bromide diminishes the activity of these functions, whilst atropine has an intermediate action, but with a tendency to their increase rather than their diminution. The effects are in proportion to the dose administered, large doses tending to a stasis, the smaller to a diminution of blood in the spinal meninges and nerve-substance.

It would seem strange (if the foregoing summary of the physiological action of belladonna be correct) that this drug should be recommended in tetanus. If in this disease there is congestion of the nervous centres or peripheries, we shall be increasing rather than diminishing the determination of blood to the capillaries and to the spinal cord, unless we should use much care in apportioning the dose; as we have seen that it is *only* in small quantity that atropine tends to diminish the amount of blood in the spinal meninges and nerve-substance. But it would be a very difficult matter to determine an amount which in every person should produce the same effect. It would be only by carefully watching that we could produce a modification of the tetanic spasms and keep the action of the drug within the limit. Thus, much caution would be required in the application of the drug to those cases in which we wished to produce oligæmia or hyperæmia in the tissues of the body.

Oligæmia of the brain resulting from a deficiency of blood-globules acts in the same way as a section of the spinal cord, or an exaggeration of the excito-motor power, and therefore we must beware, lest in avoiding Scylla we fall into Charybdis.

It may be said, that the physiological action of drugs upon man and animals is not subject to the same laws, and, frequently, does not produce the same effects. This cannot be exactly true with this drug, as its action, so far as at present known, is the same upon man and animals; provided that the drug has entered the venous circulation in a form sufficiently concentrated. Some animals can so rapidly eliminate it, that only a quantity insufficient to produce tox-

\* Paris, 1868.

ical effects, is present in the capillary circulation at one time, and hence their apparent immunity to its baneful action.\* That the urine of a goat fed with belladonna leaves was injected into the stomach of a dog with fatal results, and that his urine caused dilatation of the pupil in another dog, is a very curious fact; and shows that a dose which a dog cannot quickly enough eliminate may remain in a goat's bladder, unabsorbed into the capillary circulation. If the nrethra of the goat had been tied up, imbibition of the poison and prevention of its elimination would probably have produced a different result.

† The action upon the pupil results from a destruction of the excitability of the fifth pair of nerves. Electrization, and the action of certain exciters of muscular contractility (myotiques) upon atropinized eyes seem to show that the sphincter of the iris will preserve its power of contracting. But the feeble action that is observed from the exhibition of atropine after the section of the great sympathetic, and the different results obtained from electrization of eyes under the influence of atropine, depending on the destruction or integrity of the sympathetic nerve, seem to indicate that this drug has an exciting action upon the terminations of the sympathetic. The demonstration is also given in the effects of atropine on eyes of which the motor ocnularis communis is completely paralyzed, and experimentally on animals when the sphincter iris is destroyed. Belladonna is not a hypnotic but possibly a stupefying narcotic. In small doses it induces agitation and insomnia, in large doses stupor, in intermediate doses dreams and general tremblings.

The effect upon the temperature has been found by numerous observers to be an increase of from 1-2 to 8-10 of a degree centigrade.

Atropine causes dryness of the skin and of the mucous surfaces, probably from a re-absorption of the liquids on account of the increased rapidity of the circulating current. Thirst from atropinization may be thus accounted for. The local action of the drug upon the mouth produces salivation. As the peripheric sensibility is also diminished, the secretions are decreased. In this state acetic acid placed upon the tongue does not salivate.

Small doses augment the pressure of the blood in the kidneys, large doses diminish the pressure, and thus, according to Ber-

nard,\* in the former case we obtain diuresis, and in the latter suppression of urine.

M. Behier † recommends for tetanus subcutaneous injections of the valerianate of atropia along the nape of the neck, and gives the following formula:

R. Atropiæ valerianatis, .30 = grs. v.  
Aque, 30.00 = ʒi.

Of this 5 drops to be injected every two hours. Pescheux (Verneuil) reports a case of tetanus relieved by subcutaneous injections of atropine sol. 1-100. Three-fourths of the syringe of Pravaz (3 grammes) were injected, in doses of 10 drops at a time. Symptoms of atropic poisoning (slight) occurred, and the tetanus disappeared.

#### ATROPINE AS A REMEDY FOR TETANUS.

On the 2d of April, 1868, I received a request from Dr. Stickney to visit a horse suffering from an attack of lockjaw, in a stable in my vicinity. On inquiry I found that the animal had been ailing for a few days, and that sulphur in large quantity had been given by the hostler in charge. He had not eaten anything since Friday, and had had but little discharge from the bowels or bladder. The facial muscles and those of the neck were very rigid, though elsewhere they were but slightly if at all affected. The animal could not open his mouth, nor could it be forced open. Dr. S. had ordered him small doses of prussic acid by the rectum every two hours.

Three days afterward I was told that Dr. Stickney had given me the liberty of resorting to any expedient that might be suggested, and I went again to see the horse. He was respiring rapidly and was in much distress, and the spasmodic contractions were more extended and severe. The eyes were half closed.

It is unnecessary to give more details. The peculiarities of tetanus are well known and easily understood from the descriptions recorded in standard works. The disease had increased very rapidly during the twenty-four hours, and now there was no muscle which was not tense in a greater or less degree. Several methods occurred to my mind to try as alleviations of the spasms, as a cure was now out of the question. I had in a previous case tried hydrocyanic acid unsuccessfully. Strychnine and electricity I thought of, especially the latter. However, upon reflection I considered it advisable to ask Prof. Brown-Sé-

guard, what drug it would be advantageous to experiment with. Several drugs were discussed, but the one he preferred was atropine, and, at his advice, I publish the record of the experiment. I procured one-sixth of a grain of the sulphate of atropia, which I dissolved in two drachms of water.

At 7 P.M., on the same day, I injected subcutaneously, according to the advice of this eminent physiologist, this solution in three different doses (with ten minutes interval between each) under the fore-shoulder. The animal was under the influence of chloroform for ten minutes before the first injection was made, in order to prevent any serious agitation.

In half an hour after the last injection he discharged a moderate quantity of urine; and, as he appeared much easier, I left him for an hour. On my return I found him still more comfortable, and again three hours after the hostler told me that he had been lying down and had got up again; the muscular spasm was a little reduced, especially in the hinder part of the body.

On the next morning, the man showed me about a halfpail of soft feces that the horse had passed during the night, and said that the bedding was well soaked with his urine. I then obtained one grain more of the sulphate of atropia, which I dissolved in eight pints of water. I directed that one pint of this solution should be injected into the rectum every hour, and that between the first and second doses they should inject some milk and water. The first injection was made at 7 P.M. At 3 o'clock the man came down and said that they had succeeded in opening the horse's mouth, that he was in a great sweat, and that he had been trying to eat his bedding; he wished to know what he might give him to eat. I directed first that the medicine should be omitted; second, that they should boil some carrots and squeeze their juice into a pail of water, put in this a handful of bran and a wine-glassful of alcohol; that while this was preparing they should give him some water if he could drink it. In an hour afterwards I found him bathed in a profuse sweat, the muscles surprisingly relaxed, and the animal drinking water of his own accord from a pail. His mouth was partially open, and the eyelids so drawn up that with difficulty could I see the iris. He had drunk some of the liquid food, prepared as directed, but did not like it, probably on account of the alcohol. So I was ordering some other mixture when Dr. Stickney appeared. He was much surprised on seeing the change in the horse,

and we were both sanguine (too much so as it afterwards proved) of the animal's recovery. He said that he had never seen so sudden a change in tetanus in a horse. I asked him to prescribe the diet, and soon we left. On my return, three hours after, the animal had passed a large amount of feces, and much urine. His mouth was still open, and the muscles much relaxed, but *not* so much as on my previous examination. I therefore ordered another pint of the diluted medicine to be placed in his pail of water. He had just drunk a quantity of oatmeal gruel, and had lain down and got up again several times. Still, as the spasms were apparently stronger, I considered it important to give another dose of atropine. Two pints had been injected, making a quarter of a grain of atropine introduced into the rectum. At 9 o'clock the next morning (Wednesday, 7th) I found on inquiry that the horse was dead. On an investigation I found that at 5 o'clock a noise of kicking was heard in his stall, and the man on going down found the animal throwing his head round while lying on his side, kicking violently with all four feet, and bathed in sweat. Evidently, from his description, the horse was in a convulsion, which lasted twenty minutes or so, after which the animal expired. He said that the muscles were not very stiff, not so much so as before the atropine had been given.

A natural question is suggested, whether this was a case of traumatic tetanus? There was no proof that it was. The horse had been lying idle all winter in a cellar stable, and had been shod four weeks before his attack. He had been exposed in a paddock to our last severe snow storm, and shortly after began to ail.

#### ATROPIE VALERIANAS.

June 27th, 1868.—Tetanus. Colt 1 year old. This disease manifested itself June 26th, P.M., two weeks ago, after castration.

This morning the long muscles of the neck are distinctly marked by tension of their fibres. The membrana nictitans closes and opens itself when a hand is placed near his head. As in the last case there is hyperæsthesia of the skin. The hind legs appear stiff, though the individual muscles are not particularly tense. The wound in the scrotum appears well. There is no swelling of the sheath or neighboring parts. There is a slight running of serum from the scrotum down the legs (this I understand is perfectly normal, and another *healthy* colt, castrated at the same time, shows the same phenomenon. Respiration appears easy,

and the animal can chew grass slowly, and drink water, though the latter is swallowed more noisily and with more difficulty than is usual with horses. Fæces have passed recently and appear moist. The man in charge says that he has passed urine, but of this I have my doubts. The man is not to be relied on, as he is apt to speak as he thinks he is desired.

I administered subcutaneously a solution of atropiæ valerian., containing a little less than 1-24 gr. The puncture apparently gave a good deal of pain, though he did not seem to mind the injection of the fluid. He afterwards ate and drank as before the injection. The pupil was not dilated half an hour after the injection, nor was there any amelioration. I left directions for 1-50 gr. to be taken two hours after, and 1-24 gr. two hours after that, and another dose at 9 or 10 P.M.

The directions were carried out and a large amount of the drug was administered per rectum.

The physiological action upon the *iris* was very marked, but the disease had gained ground and the animal died three days after I first saw him. The colt had taken 2½ grs. of the drug in all. In this last case no effect upon the tetanic symptoms was observed. The disease increased, in spite of the drug, and this even while the system was showing the physiological action of this drug.

Perhaps it may be of interest to the readers of this article to give the conclusions regarding the action of Belladonna arrived at by M. Meuriot in the *brochure* before alluded to:

I. "Atropine is the active principle of belladonna, and assumes all the properties of this solanum.\*"

II. "The intensity of its action varies with the species of animals. Herbivora are less sensible to its action than the Carnivora. In man its poisonous action is the most violent; but no animal is exempt.

III. "Its action also varies with the dose employed; for small doses accelerate the heart's pulsation and augment the vascular tension; poisonous doses diminish the tension and modify the cardiac pulsations.

IV. "Belladonna is a vasculo-cardiac poison, in the classification of M. Sée. Its action produces especially the innervation of the heart and of the vessels.

V. "The varied phenomena produced by

\* In this family are also included tobacco, henbane, datura, stramonium and the dulcamara; as also the tomato, egg-plant, potato and capsicum. PROF. A. GRAY, p. 456.

Atropine depend mostly upon its primordial and elective action, or are due to the elimination of the poison.

VI. "Atropine acts upon the heart through the pneumogastric nerve, whose peripheral extremities are paralyzed. It augments the frequency of the cardiac pulsations.

VII. "In a small dose it augments the tonicity of the vascular muscles; in a poisonous dose it diminishes, and even destroys this; whence the application of Belladonna to epilepsy, in which the access seems to be due to modifications of cerebral circulation.

VIII. "The variations of the arterial tension are subordinate to the state of excitation or paralysis of the muscular coat of the vessels.

IX. "In small doses atropine accelerates the respiration; in poisonous doses it diminishes its frequency.

"The acceleration of these movements depends upon the excitation of the respiratory centres; the consecutive retardation, upon a paralysis of the extremities of the vagi nerves; whence its application in the treatment of asthma.

X. "Atropine in a therapeutical dose, increases the activity of the excito-motory functions of the spinal cord.

"In a poisonous dose it exaggerates the reflex power till it may produce convulsions.

XI. "Atropine *always* produces agitation, insomnia, delirium, and in a poisonous dose, coma; it is not at all a narcotic.

XII. "Atropine is eliminated by the kidneys, by all the mucous surfaces, and sometimes by the skin of man. Its elimination is always rapid; so that its action is of short duration.

XIII. "The effects due to elimination are numerous, viz.: redness of the mucous surfaces and of the skin, frequent desire of micturition; colic; anal and vesical tenesmus; profuse sweat, diarrhœa, &c.

XIV. "The redness and dryness of the mucous membrane explains aphonia, dysphagia, dysuria, &c.

XV. "Not only are all the secretions of the mucous membrane diminished, but there may be also, on account of the activity of the circulation, a rapid reabsorption of all the liquids which have exuded from mucous surfaces or from wounds; whence its advantage in exaggerated secretions, and its effect upon coughs, &c.

XVI. "Atropine, applied locally to the tissues, produces an activity of the capillary circulation, and, in a considerable dose, true hyperemia and sanguineous stasis.

"Angina and erythema produced by bel-

ladonna are analogous to the inflammatory process.

XVII. "The modification of the urinary secretions are dependent upon the variations of the arterial tension.

XVIII. "Belladonna is not a paralyzing agent to the smooth muscular fibres; it produces no phenomena of paralysis except in a very powerful dose, and in these cases it follows exaggerated contractions; thus it is of benefit in incontinence of urine and of the faeces, in paralysis of the bladder, in constipation, irreducible hernias, &c.

XIX. "Atropine has no elective action upon the sensitive nerves. Its local application is always followed by acute and persistent pain. Atropine acts only upon nerves in a state of hyperesthesia and often determines analgesia, but it should be applied directly upon the seat of pain (*les nerfs affectés*).

XX. "Small doses of atropine augment, toxic doses diminish, the temperature.

XXI. "Atropine, especially, possesses the property of causing dilatation of the pupil, and this is its most constant and persistent effect.

"It paralyzes the terminal branches of the third pair of nerves; this is the only fact well shown by experimental physiology, in the study of the hyoseyamus also. (Gubler, Mydriasis caused by Belladonna.)

"To this paralysis of the ciliary branches of the nervous motor ocularis communis is attached the paralysis of the muscle of accommodation.

XXII. "Certain experiments and several considerations that have been made public by the author, tend to show some exciting action upon the sympathetic nerve or upon the *dilatateur*. However, a more vigorous demonstration is still essential." \*

#### INTERESTING AND UNUSUAL CASES OF TRAUMATIC INJURY OF THE EYE.

Read before the Boston Society for Medical Improvement, Feb. 22d, 1869, by HENRY W. WILLIAMS, M.D., President of the American Ophthalmological Society; Ophthalmic Surgeon to the City Hospital of Boston.

*Fragment of Steel discovered in the Retina by means of the Ophthalmoscope, four months after its Entrance into the Eye.*—Feb. 13th, 1869.—I saw Mr. P., whose left eye had been struck by a fragment of a steel die four months previously. He described a considerable sub-conjunctival ecchymosis as having been the chief symptom observed at the time of the injury, and after this became

reabsorbed, at the end of a few days, his eye had become, and still continues, sufficiently good to allow him to resume his work of straightening blades of a machine, along which he takes sight with this eye as he has always done in preference to the other, this being as he has thought his best eye, and he being left-handed. He still reads a newspaper print with this eye, and reads No. xii. of test types at ten feet. Thinks it quite impossible that any fragment of steel can have entered the globe. His pupil is somewhat dilated and immovable, and the iris has a darker color than in the other eye. By oblique illumination, a small cicatrix is visible in the sclerótica, in the region formerly the seat of the ecchymosis; but no opacity of the transparent media can be found. His field of vision is free from obscurity, except in a small space towards the upper and outer portion, where he does not perceive objects.

Examined with the ophthalmoscope the larger part of the fundus of the eye appears normal. At the lower and inner part of the retina, in the direction indicated by the obscure spot in the field of vision, and opposite to the scleral cicatrix, is to be clearly seen a small wedge-shaped fragment of steel, having its point imbedded in the ocular tunics, and a considerable part of its dimension standing out from the retina into the vitreous. No opacity of vitreous exists in its neighborhood. An agglomeration of pigment has formed in a small circle about it, and there is a faint appearance of choroidal injection at one point only. The optic disc is slightly injected and its outline rather ill-defined. This alteration, though having no apparent relation of continuity with the changes in choroid and retina in the vicinity of the foreign body, is yet a very important evidence of want of toleration of the presence of the steel within the eye, and is of interest as regards the question as to the mode of propagation of sympathetic inflammation from one eyeball to the other.

*Rupture of the Sclerótica and Dislocation of the Crystalline Lens beneath the Conjunctiva, by a Blow from a Cow's Horn.*—Feb. 18th, 1869.—I saw Mr. P., who in stabling his cow, a fortnight previously, was struck a sudden blow with her horn in the right eye. Only very moderate pain was felt at or since this time. His condition is as follows: The crystalline lens lies beneath the conjunctiva, between the cornea and the outer canthus, the rent in the sclera through which it passed being concealed behind it. The sclerótica also bulges somewhat at the

\* Meuriot, op. cit. p. 133, et seq.

upper side of the cornea. The fundus of the eye cannot be seen with the ophthalmoscope on account of turbidity of the internal media; but the cornea is uninjured and transparent. The patient complains of only slight annoyance from the presence of the lens in its unusual situation, and the eye is only moderately injected.

The lens was at once extracted, and a suture inserted to bring together the edges of the wound in the conjunctiva and prevent any loss of vitreous. Vision is not to be hoped for, the eye having undergone, as it were, a crushing process, but there is reason to hope that the eye may retain nearly its normal size and appearance.

### "A CASE OF HERPES ZOSTER."

By ALBION CORB, M.D., Webb's Mills, Me.

The elaborate article with the above title in the *JOURNAL* for January 28th reminds me of a case of the same disease, in some respects the parallel of the one there given, which occurred in my practice.

E. B., of Casco, Maine, about 50 years old, robust, muscular, vigorous and healthy, was attacked, just about two years ago, with shingles, affecting the left side of the neck and face. Immediately on the appearance of the eruption, the left side of his face became paralyzed, exhibiting all the ordinary symptoms of facial paralysis, the most striking of which, to a casual observer, were the permanently open eye, the mouth drawn to the opposite side, and the complete want of expression in the affected side. As he treated his disease with "sovereign contempt," and kept about his ordinary business, he was not very closely observed, but the two diseases, if two they were, ran their course concurrently, and disappeared together, and Mr. B. has been perfectly well ever since.

It may be proper to state here, that, by a curious coincidence, I had under treatment, at about the same time with Mr. B., two or three cases of herpes zoster (no others of the face), and two or three cases of facial paralysis, but this is the only instance in which they occurred together.

Two or three days ago my attention was called to another case which may possibly have some bearing on the connection or relation between herpes zoster and the underlying nerves.

Capt. —, of Casco, had, about six years ago, what he and his attending physicians called shingles, covering a belt of the ordinary breadth, about the middle of the

right side of the chest. The principal distress, during the course of the disease, arose from a neuralgic pain, of a severe burning character, seeming to be seated deep in the tissues beneath the eruption. The eruption ran its usual course and disappeared, but not so the pain. This has changed neither in degree, character nor location, but has persisted up to the present time, in spite of the efforts of physicians and others to remove it. From first to last, throughout the whole six years, it has affected exactly the zone formerly occupied by the herpes.

Feb. 10, 1869.

## Hospital Reports.

### DEPRESSION AND RE-PLACEMENT OF THE SUPERIOR MAXILLA (LANGENBECK'S OPERATION).

Service of DR. CHEEVER.

CASE I.—*Naso-pharyngeal Polypus*.—(Vide Surgical Cases for 1867.) The patient was a student, aged 19 years. Thirteen months previously to his entrance to the Hospital for his present disability, he had undergone an operation for the relief of disease of which this was the recurrence; and the history of the growth dated two years and a half before that time. Its development had given rise to the following symptoms: profuse epistaxis, complete obstruction of the nostril, and the discharge of a thin and offensive fluid. Examination discovered the presence of a firm, lobulated tumor pressing down on the soft palate and filling the upper and back part of the pharynx. The general condition of the patient was good, and the growth was not painful.

*Operation*.—It was removed by temporary depression of the right upper maxilla, as follows: The primary incision was carried from near the inner canthus of the eye, downward along the fold at the side of the nose, around the ala, and through the commissure of the upper lip. The flaps were reflected so as to expose the body of the bone. The symphysis of the jaw was divided along the hard palate, and a section made with a saw across the bone from the tuberosity into the middle meatus of the nose. The section of the bone was depressed, so that it was held only by its posterior attachments. The tumor was thus exposed and reached. Its attachments to the body of the sphenoid bone and to the upper and back part of the pharynx were

divided with some difficulty with scissors, and the point of section (two inches square) cauterized with strong nitric acid. The bone was replaced and held well in position by a wire around the adjacent incisor teeth. The soft parts were easily apposed and retained by silk sutures. The hæmorrhage was inconsiderable.

The constitutional disturbance which followed the operation was comparatively slight. With a dressing of equal parts of tincture of myrrh and water, the wound healed satisfactorily, and throughout the convalescence there was no complication to impede recovery. In nineteen days, the ligatures had all come away, and there was no purulent discharge. The bone was in excellent position, and motionless. After thirty-five days he was discharged well.

Symptoms of recurrence of the growth were noticed after eleven months. The nostril became obstructed as before, and there was a feeling of fulness in the head. Otherwise than this the tumor had caused no inconvenience. There was no appearance of any disease in the pharynx, but Dr. Langmaid, with the rhinoscope, discovered the fibrous mass occupying its former position and attached, like its predecessor, to the inferior aspect of the body of the sphenoid bone and to the adjacent region of the pharynx.

*Second Operation.*—The steps in the operation for its removal, the operation being performed at once, were almost identical with those of the former one, and the lines of section were in the cicatrices of those of the year previous. Owing, however, to the thickening of the bone in the course of healing, it was necessary to remove a small portion at the inner angle, just below the orbital process, in order to expose the growth. The tumor, which was of the size of an English walnut, was removed by section of its pedicle with scissors, and the bone was thoroughly scraped. The hæmorrhage was not sufficient to require ligatures. The bone and soft parts were apposed as in the former operation; a gutta-percha plug between the teeth and a bandage around the lower jaw, and over the head, aided in supporting the parts.

Convalescence, in this case, was more rapid, even, than in the primary operation. Without complication or drawback, recovery proceeded steadily, and after twenty-seven days he was discharged with the wounds perfectly healed, and the bone firmly in place.

*CASE II.*—*Naso-pharyngeal Polypus. Operation by Temporary Depression of both*

*Superior Maxille.*—The patient was a farmer by occupation, and was 41 years old. He had suffered from the presence of a growth in the posterior nares during the previous eleven years. Its first appearance was attended with profuse epistaxis. Its rapid growth, and the inconvenience arising from its presence induced him to submit to its removal by Dr. Peaslee, by section of the soft palate, after four years. An interval of health succeeded, in which he noticed nothing of consequence from the tumor; but thirteen months before presenting himself at the Hospital he felt symptoms of its recurrence. This recurrent growth had been attended with no pain, epistaxis or other grave symptoms, although the patient was anæmic, and his mental condition was depressed and anxious.

Examination discovered the following condition of things. Externally, the facial expression was unaltered. There was no protrusion about the region of the antrum. Both nostrils were perfectly occluded, one having been closed many months, while the other had remained open until within three weeks. The palate was pressed down by a tumor protruding from the roof of the mouth, of the size of a pullet's egg; its anterior edge extended to within half an inch of the alveolar border. It was elastic, painless, and without special tenderness. In the process of development it had absorbed the palatine process of the left superior maxilla, the edge of the bone defining its border. The pharynx was clear, below the soft palate, but completely filled above.

Deglutition, respiration and articulation were considerably impaired, and complaint was especially made of the difficulty in breathing, the sensation being of fulness and of a danger of suffocation.

*Operation.*—The size of the tumor and its situation in the median region, appeared to contraindicate operation on one superior maxilla alone. Temporary depression of whole upper jaw was accordingly effected, as follows: The primary incision through the soft parts was on either side of the nose along the natural wrinkle from near the inner canthi, around the alæ and through the commissure of the myrtiliform fussa of the lips. The flaps were freely reflected, so as to expose the bone beneath as far upward as the malar prominences. With a narrow saw the body of the bone was divided from the tuberosity, forward, beneath the zygoma on each side into the middle meatus. The septum nasi and the vomer were divided with strong scissors. Nothing but the posterior attachments of the upper maxillæ now

prevented their depression; and hinging on the pterygoid processes, the upper jaw was brought down so as to expose the tumor. Its attachments were found to be to the body of the sphenoid bone, and to the ethmoid. These attachments, except the first, were divided by the finger, and a section of the growth was made by means of scissors, as near the sphenoid bone as possible, the mass being too large to deliver altogether. With a gouge chisel the remaining portion was scraped away and removed.

The whole growth was in size and shape like a large lemon. In its centre it contained a cavity with the remains of broken-down tissue. Subsequent microscopic examination determined the structure to be distinctly fibrous.

The depressed jaw was restored to its position and retained firmly by silver wire passed on each side through the malar bones. The soft parts were apposed by silk sutures; and the whole physiognomy perfectly reinstated.

The hæmorrhage during the operation did not appear to be excessive, the blood escaping externally being only of moderate amount. The attendant shock was considerable, the pulse falling off at the last until it was hardly perceptible. Stimulants by enema rallied the patient in part, but throughout the day he remained in a drowsy, unconscious state after the effects of the ether had ceased. The condition of the patient was grave from the time of the operation forward. In three hours a diarrhœa developed itself, the dejections being frequent, black, tarry and offensive, as of altered blood. Meanwhile there was no pain or nausea; the patient took nourishment, stimulants and opiates well. The pulse ranged from 128 to 136, and was small, jerky and feeble. The whole appearance was that of a patient sinking from exhaustion. The expression was listless; the skin dry and harsh; the tongue brown and parched. During the forty-eight hours after the operation there was no essential change. The diarrhœa, abdominal pain and general exhaustion continued. The wound in the face remained quiet, without sign of reaction, and there was no complaint of pain in that region.

On the third day, after continued efforts at stimulation and at control of the diarrhœa, the patient began to show more favorable symptoms. The dejections became less frequent and more natural in appearance. The mental condition was more sane. Slight suppuration commenced in the wound.

VOL. III.—No. 6A

The surface was warm and moist, and general signs of reaction became manifest.

On the following day, however, he relapsed into the former state. Jactitation, muscular tremor and mental distress succeeded. The pulse was 124, and very small; the urine was retained and catheterization was necessary. The face and conjunctivæ assumed a sallow hue. Steady sinking proceeded in spite of the stimulants, which from the beginning had been taken freely, and on the afternoon of the fifth day, one hundred and twenty hours after the operation, the patient died.

The removal of naso-pharyngeal polypi, otherwise unassailable, by a temporary displacement, instead of destruction of the superior maxilla, is known as Langenbeck's operation.

Performed here, for the first time, in the case described above, it was *repeated*, successfully, on the *same patient*.

The second patient was treated in a manner novel, so far as we know, the operation including both superior maxillary bones. Although he succumbed, we cannot but think that there is nothing in the operation itself, which should render it a fatal one. We know, at any rate, that much more serious mutilation of the jaws and face, in removing cancer, is almost always survived. The hæmorrhage was moderate, and the shock should not be excessive.

Our patient was feeble and anæmic from suffering and abstinence. The pulse was poor from the beginning. He never rallied any higher than the state known as "prostration with excitement."

We should not hesitate to repeat the double operation on a suitable case, unless resort were had to a novel plan proposed by Ollier, to saw down the nose obliquely from above downwards, and operate through the upper meatus. In this way he removed a polypus weighing six ounces.

*The Preventive Treatment of Scarlet Fever.*  
By PETER HOOD, M.D. An article in the *British Medical Journal*, Feb. 6th, 1869. p. 117.

THE *British Medical Journal* has been lately favored with several remarkable articles—remarkable for the complacency with which the writers announce their ability to prevent disease, or, "next point of importance" (Hood), to treat it with unerring

success whenever occasionally appearing through the ignorance or carelessness of others. A few more such articles and journalism is over, and the profession itself ended—there will be no “suffering humanity” to relieve.

Dr. Budd's article we recently noticed in this Journal. He merely puts a stop to the disease; Dr. Hood comes up manfully to crown the work “with a matter of even superior importance—namely, the means by which we limit” the amount of disease in the individual attacked. Dr. Budd confined his observations to the destruction of the scarlatinal germ by “external appliances,” Dr. Hood supplements these observations by his “experience of the internal treatment of scarlet fever.”

“It is ten years,” says Dr. Hood, “since I wrote a book which I was bold enough to designate as *The Successful Treatment of Scarlet Fever*. . . . I have not lost a patient with scarlet fever” (did ever charlatan do better?) “since it was published, nor during many years preceding its appearance, when” (mark the caveat) “I have attended the patient from the commencement of the illness. I have been consulted in cases that have ended fatally, but this had been when the time for medical aid had passed, and the treatment which I advocated had not been employed”!

Delays are dangerous, says the proverb, but here they are fatal; Dr. Hood should be sent for early! After such neglect, “it must not be expected,” he says, “that malignant cases . . . can always be successfully treated by any form of treatment.”

But what does he do for it? Let him speak for himself:—“To maintain the integrity of the blood as much as it is possible is one great object in the treatment of scarlet fever. In proportion as we can accomplish this, so will our success in the treatment of the disease be satisfactory or otherwise.”

“I have never known convulsions to occur unless the most common premonitory symptom—namely, vomiting—had been absent; and I can also say that, when vomiting has been induced, the convulsions have ceased.

“In the ordinary run of cases the first symptom usually complained of is headache, next soreness and swelling of the throat, followed by vomiting, and we find that the afore-mentioned symptoms are relieved by the vomiting taking place. The healthy action of the liver is interfered with, and the bile, instead of taking its natural course, finds its way into the stom-

ach, and is invariably found in the matters ejected. Hence the importance of giving an emetic at the onset of the fever, if vomiting have not occurred. . . . There is more to be apprehended from the absence of vomiting than when it is in excess. The perverted course of the bile points to a defect existing in the liver, which defect is one of congestion. Here, again, we are called upon to assist nature in relieving this important organ; no medicine operates so beneficially as a dose of calomel and scammony. And if we take the appearance of the tongue as our guide throughout the whole period of the fever, and when it is otherwise than perfectly clean, administer gentle alterative medicines, to sustain the healthy action of the liver, we shall most effectually prevent dropsy from occurring, and avoid deafness and all the other sequelae attendant on this disease.

“When the stomach has been relieved by vomiting, either by the operation of nature or art, and the liver and bowels also, by the administration of an efficient dose of medicine, it is then the proper time to avail ourselves of the antiseptic property of quinine, which drug is, according to my experience, as powerful in destroying the scarlatinal germ as it is potent in the cure of ague. I do not hesitate to say that if the previous injunction as to the emetic and purgative are attended to, any medical man who has never before employed this medicine in the treatment of scarlet fever, will never employ any other when he witnesses the gratifying progress of a case only twenty-four hours after using it. He will find the pulse diminished in frequency, the soreness of throat and difficulty of swallowing scarcely complained of, obviating all necessity for the use of gargles, sponging, caustics, &c., the heat of the skin most sensibly decreased, and the restlessness, frequently so distressing a symptom, succeeded by a calm composure. In the worst forms of scarlet fever, in which the blood of the patient is in a dyscrastic state, indicated by virulent coryza, discharges from the mouth, eyes, and ears, owing to the disintegration of the mucous surfaces, it is imperative to administer iron with the quinine, and suitable doses of the tincture of sesqui-chloride of iron, or of the sulphate of iron, should be diligently persevered with; at the same time paying strict attention to procuring a daily alvine evacuation.”

It is no wonder that a physician, who intends to carry out such a course of treatment as indicated in the foregoing extracts, for a disease which in a large majority of cases

needs no "treatment," should wish to be called early; and certainly if his patient dies he cannot be said to lose him by scarlet fever. The wonder is that a "little girl" whose case is given as an example (we hope it will prove a warning also) could survive such management for "three weeks." It certainly was a marvellous recovery.

We see that Dr. Hood is not inclined to take Dr. Budd's dictum in the matter of disinfectants. It is a pity, for when two such positive authorities differ, science suffers. Hear him, and note the criticism on his colleague's way of putting things:—

"Before I finish this paper, I must refer to one other subject connected with the treatment of scarlet fever, which I regard almost as important as the use of quinine itself. This is the disinfection of the sick room by the employment of chlorine; and here I must differ from what Dr. Budd's experience has led him to say on this subject.

"Dr. Budd has not told us in what manner he has employed disinfecting agents, chlorine more especially, to enable us to judge whether his method of using them were likely to be efficient or not.

"My experience of the beneficial effects of a free use of chlorine is directly opposed to Dr. Budd's views, and I am able to state from my own observation that, if this gas be properly used in the sick room of the patient, *the contagion of scarlet fever will be confined to that room.* My method of using it is as follows: I direct large coarse towels to be saturated with a solution of chloride of lime" (strength not stated by the writer), "and hung over the backs of chairs, and a sheet to be hung in front of the bedroom door. We may judge of the quantity required for disinfecting the room, by smell and taste (!) on going into it. This process should be continued throughout the course of the fever."

Although the profession is usually quite ready to seize upon any measures promising to exterminate, or even to relieve disease, English physicians do not yet appear to practise according to "book," though published ten years ago, for Dr. Budd states that "every year scarlet fever slays from twenty to twenty-two thousand persons in England alone."

In short, the appearance of these two papers, with another (January 30th) announcing the discovery of the "*only possible source of tubercle*" and a method to bring its ravages "to an absolute and permanent close," in a journal of such high pretensions, indicates a state of medi-

cal science in the United Kingdom hardly to have been anticipated in benighted places on this side of the water. X. Y. Z.

We have a fellow-feeling for the afflictions of the *British Medical Journal*. It is like steering between Scylla and Charybdis for an editor to avoid, on the one hand, cramping the free expression of opinion, and on the other to keep his columns from being cumbered with chaff.—En.

---

## Medical and Surgical Journal.

---

BOSTON: THURSDAY, MARCH 11, 1869.

---

THE hope we ventured to express in the JOURNAL of Feb. 11th, that the valuable letter from Dr. Dalton which we published in that issue would not be the last communication of the kind we should be able to offer, is now realized. Our readers are now addressed by "the Professor," who speaks to them as the *Autocrat* of our to-day's Editor's table.

*The Dental Cosmos: A Monthly Record of Dental Science.* Edited by J. H. McQUILLEN, D.D.S., GEORGE ZIEGLER, M.D. Observe, compare, reflect, record. Philadelphia: Samuel S. White publisher. New York, 767 and 769 Broadway; Boston, 16 Tremont Row; Chicago, 100 and 102 Randolph Street.

THE formation of a Dental School in connection with the Medical Department of Harvard University, naturally draws the attention of those engaged in medical teaching to the branch which has sought and gained their alliance. It soon becomes apparent that Dentistry has assumed an importance as a specialty of the healing art, which challenges for it an honorable recognition. The dentist of to-day stands in the same relation to the tooth-puller of a past generation as the surgeon of our time to the well-remembered worthy of the razor and the lancet, who trimmed his customer's hair or breathed a vein for him with equal skill and science.

Two arts are absolutely necessary to make old age tolerable; that of the optician and that of the dentist. Take away the old man's spectacles and leave his jaws to be dismantled without repair, and what will life be worth to him? No wonder those very sensible people we call savages, not

having either of these helps, expect their children to see that they are not left to such a fate. When the eyes of the venerable warrior can no longer read the literature tattooed on his enemy's skin, when he has lost his teeth and can no longer do justice to the *pièce de résistance* furnished by the last skirmish of his tribe, his eldest son kindly dismisses him by a single blow of his war-club to that better region where the good cannibals go, and become vegetable feeders as we charitably trust.

What would the old age of civilized life be—even in *Boston*—without convex lenses to help the failing sight; jaunty eye-glasses for public occasions, honest old straddling spectacles for solitude? No "Advertiser"—no "Transcript"—no "Atlantic"—no "Every Saturday"—no "Boston Medical and Surgical Journal"—would not the wretched dweller by the Frog-pond be glad to introduce the popular institutions of the South-sea islanders?

Or take that other wrong of advancing years, the bitterest insult to the decaying bodily fabric which precedes the last "disgrace and ignominy of our natures," as death is spoken of by Sir Thomas Brown. To have the broad many jaws, once glittering with enamelled ivory, changed to the miserable likeness of a turtle's, by the gradual absorption and thinning of their edges; to meet one's friends with a face that shuts up like an accordion; to mumble inarticulate words with organs that once held the listener captive with speech or song; to come back of necessity to the pulpy food of childhood, without its innocent appetite and unquestioning digestion—what a fate to think of! and yet that is what nature has in store for the old and for many who are not old, save that art comes in and with infinite skill and almost miraculous success arrests the progress of destruction and repairs and restores the waste that Time has already made. That was a most impressive testimony to the need of these organs to make life tolerable which was reported a few years since, in one of our periodicals, of a celebrated personage. He had lost his mind, he said, but that he could do without; but he had lost his teeth and could not eat—this was the burden of his old age.

Those who have been led to take an interest in dental matters will be glad to know where they can learn of the condition and progress of an art which is every day coming nearer to a science.

The *Dental Cosmos*, a monthly journal, published at Philadelphia, is an organ of the dental profession which has so many

excellencies that it deserves to be known outside the immediate circle of those for whom it is more especially intended. The object of this communication is to direct attention to it as containing much information which will prove useful to any intelligent practitioner.

The first point about it that strikes the reader is the handsome form in which it presents itself, comparing very well for elegance with that of the leading literary journals. The eye is next attracted by the great number of illustrated advertisements, by looking over which one may get a very good idea of many of the mechanical novelties, the chairs, plastic as cataleptic patients and rigid as these are, when any position is once fixed for them; the noiseless lathes; the remorseless forceps; the searching excavators; the wicked nerve-extractors—most of which we have seen and some of which we have felt, the greater number of us, and the many other contrivances which recommend themselves to the great community of dentists.

To give some notice of the character of this Journal, let us examine a few of the last numbers, and glance at one here and there of older date. And first as to the way the Journal is made up. The number for January, 1869, for instance, begins with twenty-five pages of original communications. Then, follow the pages of the Proceedings of Dental Societies. Then four pages of Editorial Matter. Then a Legal Opinion in Rubber suits—cases in court, not waterproof garments. Then "Periscope of Medical and General Science in their relations to Dentistry," sixteen pages. With regard to this last department, it is only justice to say that it is an admirable selection, which cannot fail to interest every medical reader. Few of our medical journals get together so many valuable selections in so small a compass. Dr. Ziegler shows an extent of reading and a good judgment in his management of this department deserving of special commendation.

The original articles are of various degrees of merit, from the most valuable practical papers of men whose skill is known to the world to the modest essay of the young practitioner whose intellectual first molars, just emerging, show promise of a better furnished mental arch by and by.

In this January number, which is taken as a specimen only because it is the last, the first article is a practical one on *pivot teeth*, which we learn have been rapidly falling into disuse, notwithstanding their advantages. When it is remembered that a

fang has been known to support an artificial crown forty years, as a writer in another number of the "Cosmos" tells us, mentioning the gentleman who had carried it all this time, we may see what advantages this mode of repairing damages must present in certain cases.

Dr. Evans, of Paris, known everywhere, writes on the Physiological Action of Nitrous Oxide Gas, a subject which is of course interesting in his hands. Dr. R. Shelton Mackenzie contributes a very curious and very pleasant paper on the Disin-terment of the Remains of William Rufus, historical, archæological and dental in its character. A second instalment follows of "The Inhabitants of the Mouth and Teeth"—a microscopic examination of the fauna and flora—the forests, meadows, mushroom beds, menageries and breeding places of that well-stocked region of the human body which we call ours, as if it were not the paradise of an innumerable creation for which we are the purveyors. Dr. Crowe writes about "Soap as a Dentifrice" and quotes Dr. Francis of New York—not referring to the labors of Dr. Bowditch, of which he should be reminded. An article by Dr. Latimer, giving the results of experiments on staining the dental tissues, and a new case of third dentition complete the list of original contributions, which may be read from beginning to end with profit and pleasure. Among the "Proceedings of Dental Societies" the report of the meetings of the Odontographic Society of Philadelphia is particularly interesting, as it has generally proved in preceding numbers. The microscopic preparations of Mr. Walmsley and those of Mr. Starr, specimens of both of which were kindly forwarded to the writer of this article, excited just admiration. Three microscopic botanical specimens of the former gentleman's preparing, presented by him to the writer, delight all who see them by their singular beauty. The senior editor of the Journal confirms some of his former results, to be mentioned presently, as to the effects of narcosis produced by nitrous oxide, and refers to some new observations as to their effect on the blood corpuscles. Then follow the numerous valuable excerpts from the different journals which have been already commended for their excellence as a selection.

This is certainly a good list of contents for any monthly Journal, and there is nothing in it as a whole which distinguishes this number as of more than average excellence.

Running over our file of the *Cosmos* for the

last two years, a few articles which happen to attract our attention may be referred to.

A valuable table in the number for February, 1867, gives the location of decay in 694 cases. Following this is a brief article in which we find this very striking and suggestive statement. "I will merely mention one analogy which is well known, and has, I think, been before mentioned in this connection, that in the teeth of neat cattle, as they roam their native pastures, decay is never known, while in their "artificial mode of life," in the swill-milk stables, the teeth suffer the same phenomena of decay as do those of man."

Prominent among the original contributions are those of the Senior Editor, Prof. McQuillen, on the microscopic anatomy of the teeth. His preparations, illustrated by figures in the text of his articles, demonstrate in the most satisfactory manner the *interglobular spaces* described by Czermak, and reproduced in the American edition of Kölliker's Microscopic Anatomy. The writer is familiar with these specimens, some of which have been sent him by Professor McQuillen, showing just the aspect figured by Czermak, and are constantly used in demonstrations before the classes at the Medical College. There was some unwillingness to accept the "interglobular spaces" which these very successful preparations were quite sufficient to overcome. Not more interesting, perhaps, but of more immediate practical importance, are Prof. McQuillen's experiments performed before the members of the Odontographic Society and the Biological and Microscopical Department of the Academy of Natural Sciences, to test the statement of Dr. B. Ward Richardson, of London, as to the fatal effects of nitrous oxide on animals. These valuable experiments, showing that animals readily recover from complete narcosis produced by the gas in question, are to be found in the number for last October. Since those experiments Professor McQuillen has kept a rabbit completely narcotized by the same agent more than an hour without any permanent injury.

Dr. Thomas W. Evans, of Paris, suggests the use of nitrous oxide liquefied by pressure. Liable to blow up, says the timid practitioner. Of course it is, says Dr. Evans—so is a soda bottle.—Why not a stub-twig flask in one's pocket by and by, with a hundred gallons, more or less, of condensed gas in the volume of a pint, with no more fear of its blowing up than we have of a gun or a pistol?

A singular case of hemiplegia, accompa-

nied by the symptoms long known under the somewhat equivocal name "spinal irritation," apparently relieved by the extraction of decayed teeth, is reported by Dr. J. L. Suesserott in the number for November, 1868.

Dr. Flagg's four articles on "Arsenious Acid as a Revitalizer of the Dental Pulp," will be valued by all the working members of his profession.

And lastly, we may mention as of the first importance for the consideration of every dentist, an article by Dr. J. T. Codman, of Boston, on "Artistic or Expressional Dentistry." It is perfectly true, as Dr. Codman says, that the natural teeth are the best guide in replacing those which are gone; but if these are all lost, judgment and the eye of an artist are necessary to give or restore the normal expression.

How many pitiable instances does this very useful paper recall of friends whom we have known as public characters, whom we knew by their portraits, whose whole physiognomy has been utterly changed by their dentist! Perhaps the contour of Washington's majestic face could not have been preserved after he was forced to trust himself in the hands of the dentist, but one cannot help thinking that if some of our skilful practitioners of to-day had had the shaping of that immortal *ratelier* which lies behind the lips to which the statuary and the painter tried in vain to give expression, the Father of his Country would have looked upon us with a still nobler aspect. And with what a sad surprise do we greet our friend who has just come from the hands of some tasteless workman in dental porcelain, who has filled his mouth with a set of "dominoes," as the pugilists call them, staring and glaring and cheating him of all his natural expression, so that to talk with him is like making a new acquaintance, and we feel as if we were taking a liberty in speaking without an introduction!

The Dental Profession is doing itself great honor by the breadth of the studies which it encourages as well as by the vast amount of ingenuity which it calls into exercise. The debt of mankind to its labors is incalculable. Many a man, still more many a woman, would rather not live at all than live disgraced by the wrongs of nature—if we may lay the fault to nature and not to artificial habits—shut out from all the charms of social intercourse by imperfect articulation and the sense of deformity, and it may be condemned to invalidism by failure of the first process of reduction of the food. There is nothing the dental art does not attempt,

and hardly anything within the bounds of reasonable belief it does not accomplish. It fills the teeth that would have been gone in a year, and makes them last a lifetime. It builds up a new fabric on what seemed the most worthless foundations, until like a monarch, the ancient fang wears a crown of solid gold, and the miracle of the legend is made an every-day fact. It straightens the most perverse irregularities, weeds the over-crowded arches, fills the gaps which disenchant the smile of beauty, enameling the delicate substitute to the exact shade of the lost pearl, lulls the patient into a pleasing trance while it clears away the incumbrances that no longer serve him, and makes him once more comely and happy with a third dentition of gold and porcelain.

It is a pleasure to pay a tribute of respect to such an art, and to call the attention of all who love medical literature to a Journal like the *Dental Cosmos*. O. W. H.

Feb. 4, 1868.

#### NOTES FROM THE UNION MEDICALE.

*Poisonous Dye-stuff in certain English Hosiery—Coralline, or Peonine.*—Our readers are familiar with the accounts of the poisonous effects alleged to have resulted from the use of certain English stockings having a peculiar red color. There have been various theories of the chemical composition of the dye producing the noxious results described. Prof. Tardieu has been investigating the matter.

In May, 1868, M. Tardieu, before he was cognizant of the facts which have since become so widely known, was consulted by a young man, 23 years old, of admirable constitution, and exempt from all herpetic taint, who was affected with a vesicular eruption on both feet. The eruption, which was quite acute and very painful, might, at first sight, have been taken for eczema. It was limited with precision to the part of the foot covered by the shoe, involving both the upper surface and the sole, and not extending backwards beyond the "roots" of the toes. The skin was violently inflamed, swollen, of a uniform redness, and studded with innumerable little vesicles, which at certain points, especially on the sole, united to form large bullæ filled with a sero-purulent liquid. There was general *malaise*, fever, headache, and sickness at the stomach. Emollients and repose were enjoined. In two days the general symptoms had disappeared. But the feet did not get well under about three weeks. In another case, stockings striped with the color in question were used; and the inflammation of the skin was, here, limited to the parts in contact with the red lines. An American lady in Paris was similarly affected from

wearing silk stockings of the mischievous red color.

A skilful chemist, M. L. Roussin, assisted M. Tardieu in his experiments. They took the socks worn by the young man first mentioned, and soaked them in cold water, boiling water, acidulated water, and water rendered alkaline; but obtained nothing soluble. Alcohol, however, boiling at 85 degrees (centigrade, probably), rapidly dissolved the red coloring matter. By evaporation to dryness, an extract was obtained. This extract, re-dissolved in a little alcohol, was injected under the skin of a dog, of a rabbit, and of a frog. The three animals died—the frog in four hours, the dog in thirty-six hours, the rabbit in two days. The dog and rabbit had excessively abundant and almost incessant stools.

The coloring matter, M. Tardieu says, being called *coralline* or *peonine*, is derived from *acide rosolique*, which is in turn obtained by oxidation from phenic (carbolic) acid. Having obtained specimens of it from M. Persoz fils, who discovered it in 1860, M. Tardieu made further experiments with it on animals, which showed it to be a violent poison. *Post-mortem* examination revealed violent inflammation, with purulent infiltration of the cellular tissue at point of injection; stomach healthy; intestines distended with an enormous quantity of liquid fecal matter, and presenting manifest traces of acute inflammation of the mucous membrane; liver affected with fatty degeneration, demonstrated by the microscope. M. Tardieu lays great stress on the fact that the lungs were beautifully and uniformly tinted with the coloring matter. This substance, having been extracted from the lungs and livers of the animals poisoned with it, dyed a skein of silk with its own tint.

M. Tardieu compares the action of coralline to that of croton oil, both in its local and general effects; and asks if the symptoms produced in the human subject by the former—fever, headache, vertigo, nausea—were simply provoked by the local inflammation, or if they were not rather the consequence and the indication of absorption of the poison. He also calls attention to the fact that the coralline is not soluble in water, and yet in producing the lesion of the foot, had no other solvent than the secretions of the skin. This became the point of departure for a discussion (which was, as it were, adjourned without being decided), at the Imperial Academy, as to whether certain substances not capable, while in watery solution, of absorption by the skin, can be absorbed by the cutaneous surface, when they are in the form of powder, or mingled with oily matter.

In the course of the discussion, it was stated that M. Roussin, after having remained for five (5) hours in a bath containing five hundred (500)

grammes of iodide of potassium in solution, was unable to detect the slightest trace of that substance in the urine or the saliva. But, after having left the bath, he allowed the moisture to evaporate from the surface of the body, so as to leave a layer of iodide of potassium on the skin; and, in a little while, the salt was detected both in the urine and in the saliva.

#### *Chronic Albuminuria of a Benign Character.*—

M. Dumontpallier has been the medical adviser, for some years, of a young man, of gouty habit, whose general condition, says Dr. D., is so satisfactory that he would never be suspected of having albuminuria, but in whom the urine contains albumen. On the basis of this case, M. D. claims that there is such a thing as a chronic albuminuria of long standing, which is not necessarily the expression of a grave deviation from health. The reporter adds that Rayer, who had given much attention to the disease, and also Trousseau, with his vast clinical experience, had both said to him, in their latter years, that much investigation was still requisite to complete the prognosis of albuminuria.

MASSACHUSETTS MEDICAL COLLEGE.—The following are the names of the gentlemen who received their degrees on the 10th inst., with their residences and theses annexed:—

#### *Members of the Class graduating in Medicine.*

Bassett, Elton James, Taunton, Scarlatina.  
 Baylies, Alfred Wood, Taunton, Rubcola.  
 Bent, William Henry, Dighy, N. S., Pyæmia.  
 Bradford, Enoch Freeman, Turner, Me., Diseases of the Heart.  
 Brown, Henry Nelson, N. Scituate, R. I., Diabetes.  
 Burden, Frederick Lysander, Scituate, R. I., Hæmorrhage.  
 Buttrick, Abner Wheeler, Lowell, Tania Solium.  
 Campbell, Duncan, Inverness, N. S., Erysipelas.  
 Carter, William Gardner, Concord, N. H., Typhoid Fever.  
 Chisholm, Donald, Inverness, N. S., Absorption.  
 Cleaves, Royal Lewis, Bridgeton, Me., Generation.  
 Clough, Benjamin Franklin, Boston, Intermittent Fever.  
 Collie, James Ross, Pictou, N. S., Catharisis.  
 Daley, James, Lawrence, Endocardial Murmurs.  
 Davis, Sumner Danforth, Scranton, Pa., Diphtheria.  
 Dodge, William Lovell, Springfield, Vt., Dysentery.  
 Doe, Orlando Witherspoon, Boston, Lead Poisoning.  
 Dorsey, Thomas Graham, Philadelphia, Pa., Prolapsus of the Uterus.  
 Dow, William Wellman, Dover, N. H., Hæmoptysis.  
 Draper, Frank Winthrop, Wayland, Ergot of Rye.  
 Emery, Erastus, Binghamton, N. Y., Hydrærgyrum.  
 Fellows, Willis Mott, Lowell, Articular Rheumatism.  
 Fogg, Edmund Eastman, Limerick, Me., Opium.  
 Fulton, Jonathan Borden, Boston, Inflammation.  
 Gage, William Hathorne, Exeter, N. H., Inflammation.  
 Galligan, Francis Edward, Taunton, Amenorrhæa.  
 Goldsmith, Charles Almon, Auburn, N. H., Spermatorrhæa.  
 Goss, Francis Webster, Salem, Digitalis Purpurea.  
 Hahn, Ammi Ruhamah, East Boston, Surgical Hæmorrhage.  
 Ham, Edward Bartlett, Dover, N. H., Mechanism of Natural Labor.  
 Hibbard, William Warner, Worcester, Mind in Disease.  
 Hills, William Henry, Westminster, N. S., Nervous Diathesis.  
 Hodgson, Abner, Cumberland, N. S., Pneumonia.  
 Howard, Edwin Clarence, Boston, Puerperal Fever.

Johnson, Horatio Huntington, *Belfast, Me.*, Hernia.  
 Kent, John Bryden, *Nova Scotia*, Diptheria.  
 Knight, Benjamin Jr., *Providence, R. I.*, Hysteria.  
 Logan, William Henry, *East Boston*, Alcohol.  
 Mansfield, Henry Tucker, *Boston*, Acute Rheumatism.  
 Mangeson, Charles Inglis, *Wilmington, N. S.*, Cerebro-Spinal Meningitis.  
 McCollom, John Hildreth, *Medford*, Hip Disease.  
 McKay, John Graham, *Charlottetown, P. E. I.*, Life and Death.  
 Newhall, Edward George, *Galena, Ill.*, Asiatic Cholera.  
 Nichols, Algernon Sidney, *Haverhill*, Syphilis.  
 Okie, Howard, *Providence, R. I.*, Tubercular Meningitis.  
 Parker, Francis Fullam, *Springfield, Vt.*, Vis Medicatrix Nature.  
 Pedoin, Ferdinand Lorek, *Fredericton, N. B.*, Pneumonia.  
 Peirce, Warren, *Mendon*, Diptheria.  
 Pillsbury, Geo. Harlin, *Lowell*, Hypodermic Injections.  
 Reynolds, Henry, *E. Wotton, Me.*, Uterine Displacement.  
 Rose, Daniel Campbell, *Eastport, Me.*, Diptheria.  
 Sunders, Daniel Oliver, *Nova Scotia*, Spermatorrhœa.  
 Simpson, James Lund, *Glassville, N. B.*, Diaphoresis.  
 Smith, John Peter, *Pictou, N. S.*, Placenta.  
 Stevens, Andrew Jackson, *Haverhill*, Ovariectomy.  
 Vail, William Edwin, *Sussex Vale, N. B.*, Digestion.  
 Wilson, Charles Alonzo, *Gardner*, Scrofula.  
 Wood, Edward Addison, *Groton*, Variola.

*Members of the Class Graduating in Dental Medicine.*  
 Freeman, Robert Tanner, *Washington, D. C.*, Importance of Preserving the Teeth.

Fillebrown, Thomas, *Leviston, Me.*, Non-assimilation of Food as a Cause of Impaired Dentition.  
 Haley, Thomas, *Biddeford, Me.*, Dental Caries.  
 Page, Edward, *Charlestown, Mass.*, Nitrous Oxide.  
 Shaw, Samuel J., *Marlboro', Mass.*, Extracting Teeth.  
 Vincent, Joseph J., *Amherst, Mass.*, Dental Manipulations.

**CHOREA.** By SAMUEL WILKS, M.D., Physician to, and Lecturer on the Practice of Medicine at, Guy's Hospital.— . . . . . A more usual opinion, however, is that the order of sequence is rheumatism, cardiac affection, and chorea; and thus a theory is held, which was first propagated by Dr. Kirkes, that embolic particles are carried from the heart to the spine, and there set up the irritation which is productive of chorea. This of course is a mere opinion, and not proved to be correct either in fact or in theory. . . . .

I should very much doubt whether chorea is due to any special disease of the spinal cord or other part of the nervous system, but rather, like epilepsy, due to a disturbance of the whole of the centres. That the brain is affected is shown by the occasional maniacal excitement and the more frequent tendency to imbecility. Just as in epilepsy you may find a sudden disruption or discharge of nervous force exciting the ganglia below, and temporarily suspending the action of the cerebral hemisphere in which the explosion took place, so in chorea the irritation is more continuous, and the movements consequently constant. Hence, when any extra work is put on the cineritious matter of the hemispheres, as when volition comes into play, the movements are increased. The common cause of fright would also seem to show that the first shock was mental, or imposed on the cerebrum. It is a condition in which the nervous centres have become irritable, lost their power, and the will is incapable of directing their action. A strong voluntary effort is capable for a moment of restraining the movements, but time is necessary for the power to be regained. In those cases where the complaint remains chronic,

and more especially in those instances where the choreal movement is confined to one part of the body, it ceases to be a disease in the ordinary acceptance of the term; the movement is simply a bad habit. Just as the spinal cord is educated to perform ordinary routine movements, such as take place in walking or in playing a tune, when the mind is otherwise engaged, so the spinal cord may be badly educated, or have become habituated to produce certain strange movements, which require a great effort of the will or training to entirely overcome. In such chronic cases medicine is of little use.

*Treatment.*— . . . . Morphia, as far as I have seen, is useless. I can call to mind two cases where large doses were given, but the effect was only transitory. The same with chloroform; the vapor produces but a temporary tranquillizing effect, and our experience of it is not encouraging either in chorea or in the allied disorders, tetanus and hydrophobia. I have never seen strychnia of any use in the acute affection; and the same of belladonna and conia. In the less severe cases it is possible that one or two of these medicines may be useful, but I feel convinced that the class of medicines of which I speak—those which have a physiological action on the nervous system—are far less efficacious than the metallic tonics. It would seem that in order to produce a cure a bracing up or restoration of the original nerve power is necessary, and that the mere subdual of symptoms in no way tends to cure the complaint. When I say this I speak with some little hesitation of the effects of belladonna and conium, both of which remedies I have seen apparently useful. I remember when at Paris some years ago hearing Trousseau give a lecture on this disease and warmly recommend belladonna. On another occasion he was declaring that there was no drug in the Pharmacopœia equal to strong coffee, and on a third occasion he was vaunting the new gymnasium at the Hospital for Sick Children as the best therapeutic agent he knew. I mention this to show that there really is no specific treatment for the disease. I might say that we thought we saw some benefit in one case after the use of cannabis indica, but none whatever in four cases in which we tried the physostigma.

I believe I can tell you something very positive about the treatment of chorea, and I only wish I was enabled to make the same boast in reference to some other diseases. Many years ago, seeing that every medicine in the Pharmacopœia as well as several others out of it, were said to be equal to the cure of chorea, I determined to watch the disease untrammelled by medicines, and I found that in many cases a speedy recovery took place without the administration of any medicine whatever. . . . I should say that a weakened condition of the nervous centres being at the root of the malady, good nourishment and the tonic plan are necessary. . . . I believe Dr. Elliotson many years ago acquired great fame by his success in the treatment of chorea, his remedy, as you know, being the red oxide of iron. We still give it, and it is one of the best of remedies; our children very willingly take half-drachm doses in treacle. Probably an equally favorite remedy here is the zinc—in fact, it is the medicine most commonly given, beginning with grain doses, and increasing to any

amount, as a scruple three times daily. A favorite remedy of my late colleague Dr. Hughes was rhubarb steeped in port wine; the children were thus well kept up at the same time that the stomach and bowels were improved in condition. . . .  
—*London Medical Times and Gazette.*

DR. BATEMAN's paper on Aphasia, read at the last meeting of the Medical Society of London, aimed another blow, if one were necessary, at Broca's defunct theory of localization of speech in the third left frontal convolution. Dr. Bateman gave a good *résumé* of opinions on the subject, and stated, in conclusion, that he doubted the existence of any centre of speech. He believed that aphasia might depend on want of co-ordinate action as well as upon appreciable lesions of the nervous system.—*Ibid.*

SUTURE OF THE TENDO-ACHILLIS.—M. Delore, of the Charité Hospital, Lyons, relates the case of a boy, 9 years of age, who was brought to that Hospital twelve days after his tendo-Achillis had been cleft by a small hatchet. A separation of four centimetres existed between the two parts of the tendon. These were cut down to, and after some adhesions had been separated, and the edges of the tendon pared, these were brought into contact by four points of metallic suture. The leg was so fixed that no traction was exerted on the sutures. In from ten to fourteen days all the sutures were removed without union having taken place. There was, however, no separation, and the limb was kept in the same position, the starch bandage not being removed until the fifty-second day. Six weeks were required to restore the complete mobility of the limb after being so long fixed, but at the end of that time the boy had recovered complete use of the extremity. No separation between the ends of the tendon now existed, some adhesion having, however, taken place between it and the skin covering it.—*Ibid.* from *Bull. de Thérap.*, September 15.

FORCED AND PROLONGED FLEXION OF THE LIMBS IN TRAUMATIC HÆMORRHAGE.—M. von Adelmann, of Dorpat, in a paper laid before the Belgian Academy of Medicine, and founded upon ten cases occurring in his practice, arrives at the following conclusions:—1. Forced flexion is a valuable means of arresting traumatic hæmorrhage. 2. It should be employed before having recourse to other hæmostatic agents. 3. It may be resorted to even in cases in which ligation of the artery has failed. 4. A knowledge of its mode of application should be properly diffused, so as to allow of its being at once adopted while awaiting the arrival of the Surgeon. 5. Such knowledge may also be very useful in armies. 6. It is very desirable that manuals of Surgery should bring the subject into prominent notice.—*Ibid.* from *Presse Belge.*

NEURALGIA OF THE INTERNAL SAPHENOUS NERVE.—M. Bousseau related two cases to the *Société Médicale d'Observation*, which he believes may be thus correctly denominated. He says: 1. This form of neuralgia manifests all the characters observed in the neuralgias of the principal nerves of the trunk and limbs. 2. It is sometimes directed

towards the termination of the nerve, and at others mounts up from these towards its main trunk. 3. It may exist alone or concurrently with neuralgia of other branches of the crural nerve, and with that of the sciatic nerve. 4. It is a very rare affection, and is promptly ameliorated by injections of sulphate of atropia.—*Ibid.* from *Gazette des Hôp.*

LABARRAQUE'S WINE OF QUINUM. By WM. PROCTER, JR.—A correspondent desires to be informed, through the columns of this Journal, of an easy method of preparing Labarraque's *Vin de Quinum*.

"Quinum" is a name given by M. Labarraque to the crude quinine or alcoholic extract of cinchona by lime. According to M. Dorvault (*Ollivier* p. 520, edit. 1858), it is prepared as follows: Take such a mixture of cinchona bark as shall contain about 2 per cent. of quinia and one of cinchonia, bruise it finely and add to it half its weight of hydrated lime in powder. Treat the mixture with boiling alcohol till exhausted, and distil off the alcohol from the resulting tincture by aid of a water or steam bath to dryness. The residue is *quinum*, which contains 33 per cent. of its weight in cinchona alkaloids. It is therefore very much richer in alkaloids than the best extracts of cinchona, and the preparations made from it are of course easily made more active, and as it is graduated in strength, more uniform.

*Wine of quinum* is prepared by dissolving 44 parts of quinum in 1000 parts of white wine, such as sherry and madeira; this is about equal to 35 grains to the pint. M. Dorvault says the dose is from three to six fluidounces in 24 hours as an antiperiodic in fevers, and from an ounce and a half to three ounces per day as a tonic.

We do not know the precise solubility of quinum, but may hazard the opinion that a stronger solution with a less dose would be preferable when the stimulating effects of the alcohol are not needed.—*American Journal of Pharmacy.*

THE COMMUNICABILITY OF PHTHISIS.—In a letter to the editor of the *Medical Times and Gazette*, R. P. Cotton, M.D., Senior Physician to the Hospital for Consumption, Brompton, says:—"My attention has but just now been directed to an abstract of a paper by Dr. Elliott upon the communicability of phthisis, in the last number of last year's *Medical Times and Gazette*. Dr. Elliott appears to be a firm believer in Dr. Budd's theory of the zymotic character of consumption, and supports his views by asserting 'the frequency of phthisis amongst the nurses of the Brompton Hospital.' As such a statement (given, I would observe, without any authority) is quite opposed to fact, and the question is of grave importance, I hope you will allow me, although somewhat late in doing so, to refer Dr. Elliott and those of your readers interested in the subject to a detailed report of mine on this very matter published in the *Lancet* of Nov. 2, 1867, as a reply to Dr. Budd's views. It will there be seen that the nurses and other resident and non-resident officials connected with the Hospital for Consumption at Brompton have been always remarkably free from phthisis, affording in this respect very evident and strong testimony in favor of the non-communicability of the disease."

## Medical Miscellany.

THE "Dearborn Branch" of the Boston Dispensary, thus named in honor of the late Benjamin Dearborn, the greatest benefactor of the institution, will be opened for the treatment of the sick poor on Monday next, the 15th inst.

The three rooms awarded by the City to the Dispensary are situated in the basement story of the new Charity Bureau on Chardon Street. The central room is to be devoted to the reception of patients, and the others respectively to the treatment of medical and surgical cases. The hours of service are the same as at the central office, viz., from 9 to 11, A.M., except on Sundays and legal holidays. This branch is intended for the benefit of the poor in the north and northwestern parts of the city. Provision has been made by which prescriptions can be purchased of a neighboring druggist at a very low cost by those who can afford it; others can be served as heretofore at the central office.

We trust the day is not far distant when the funds of the Dispensary will allow the establishment of similar branches in East and South Boston, as well as in the Highland District.

At a meeting of the Executive Committee of the Dispensary, the following gentlemen were elected to compose the staff at the new branch of the Dispensary:—As Physicians, F. E. Oliver, M.D., T. W. Fisher, M.D., Robert Amory, M.D., Thomas Waterman, M.D. As Surgeons, A. Coolidge, M.D., G. G. Tarbell, M.D., A. H. Nichols, M.D., H. H. A. Beach, M.D.

WE regret to see that the Legislature of the State of Maine has indefinitely postponed the bill for the legalization of anatomy. It is obvious, we think, that either there can be no proper study of medicine in that State, or else anatomy will be studied with the aid of dissections, *legal or illegal*.

WE tender our thanks to Messrs. Codman & Shurtleff for one of their "atomizing apparatus, No. 5." The instrument is worked by the hand, and is all that could be desired. Messrs. C. & S. furnish tubes which can be adapted to the air-driving part of the apparatus, for the purpose of producing local anæsthesia.

The same manufacturers have also sent us one of their improved steam atomizers. We have seen one of these in use by a patient, and it operates to the entire satisfaction of all parties concerned.

GRISOLLE died on the 10th of February last, in the 58th year of his age. He had been withdrawn from the world of science for three years previously, by a stroke of apoplexy. At the funeral, which recently took place in Paris, the pall-bearers were the Dean of the Faculty of Medicine; M. Blache, President of the Academy of Medicine; M. Husson, Director of *l'Assistance Publique*; and a member of the *Société Médicale des Hôpitaux*. Addresses were pronounced at the tomb by M. Belier, M. Chauffard, and M. Millard.

At the annual meeting of the Boston Academy of Homœopathic Medicine, January, 1869, Dr. Gregg said:—

"The discussion naturally leads to the consideration of the prophylactic properties of *belladonna* in scarlatina. In many instances he had administered this remedy with a view to prophylaxis. In some cases the disease did not occur in those to whom it was given, but in the majority of cases it was otherwise, the disease spreading to other members of the family with the same facility as if they had not taken the *belladonna*.

"He had seen an equal number of isolated cases of the disease in families where the *belladonna* had not been given as in those where it had. He therefore regarded the prophylactic powers of *belladonna* in scarlatina as wholly theoretical and unreliable."

DR. POULET, of Plancher-les-Mines (Haute-Saône), France, has sent in a paper to the Academy of Sciences, to show that alcohol, taken in large doses, is a sure specific in cases of poisoning by mushrooms, especially by those of the amanita genus.

LARYNGOSCOPY was discovered in 1854, by Garcia, a London music teacher. Czermak, of Prague, first made the art available.

## MEDICAL DIARY OF THE WEEK.

MONDAY, 9, A.M., Massachusetts General Hospital, Med. Clinic. 9, A.M., City Hospital, Ophthalmic Clinic.

TUESDAY, 9, A.M., City Hospital, Medical Clinic; 10, A.M., Surgical Lecture. 9 to 11, A.M., Boston Dispensary. 10-11, A.M., Massachusetts Eye and Ear Infirmary.

THURSDAY, 10 A.M., Massachusetts General Hospital, Surgical Visit. 11 A.M., OPERATIONS.

FRIDAY, 9, A.M., City Hospital, Ophthalmic Clinic; 10, A.M., Surgical Visit; 11, A.M., OPERATIONS. 9 to 11, A.M., Boston Dispensary.

SATURDAY, 10, A.M., Massachusetts General Hospital Surgical Visit; 11, A.M., OPERATIONS.

ERRATA.—The line in the second parenthesis on page 94 should read simply (Gubler), without the remaining words.—In the article on "Cerebral Amaurosis," in last week's JOURNAL, for "optic tracks" read *optic tracts*.

TO CORRESPONDENTS.—The following communication has been received:—Neurasthenia, or Nervous Exhaustion. The paper on Disease of the Supra-renal Capsules will appear early in April.

DEATHS IN BOSTON for the week ending Saturday noon, March 6th, 119. Males, 59—Females, 60.—Accident, 1—apoplexy, 2— inflammation of the bowels, 1—congestion of the brain, 2—disease of the brain, 3— inflammation of the brain, 3—bronchitis, 3—cancer, 1—consumption, 15—convulsions, 1—croup, 4—cystitis, 2—dropsy, 1—dropsy of the brain, 5—dysentery, 1—erysipelas, 3—scarlet fever, 14—typhoid fever, 3—hemorrhage, 1—disease of the heart, 6—hernia, 1—infantile disease, 4—intemperance, 1—jaundice, 1—disease of the kidneys, 1—disease of the liver, 2—congestion of the lungs, 3— inflammation of the lungs, 8—marasmus, 1—old age, 4—paralysis, 1—enlargement of the prostate, 1—puerperal disease, 6—unknown, 11—organic disease of the uterus, 1—whooping-cough, 2.

TREATMENT OF DISEASES OF THE LACHRYMAL SAC.

From an Article by Professor ARLT.\*

[Translated for the Journal by HASKET DERRY, M.D.]

[This important subject seems in our community to be very generally misapprehended. The ophthalmic surgeon receives constant applications, from sufferers with such affections, for the insertion of the style or the passage of the probe from below into the nasal duct. And occasionally practitioners are found to be unaware that these methods are now happily obsolete. In the face of this it has seemed to the translator that the following selections from the able article just published by Professor Arlt, the occupant of the chair of Ophthalmology at Vienna, and one of the most eminent authorities of the day, might profitably be transferred to the columns of the JOURNAL.]

The anatomy of the parts is first elaborately discussed and illustrated by various drawings from nature, sections of frozen heads being employed. From this the proper rules for the passage of the probe are deduced. It is shown that though, after the method of Bowman, the canaliculus be thoroughly divided, it can never be kept open through more than half its length, a fact that has an important practical bearing. Denuded bone and entire occlusion of the sac are declared to be of comparatively infrequent occurrence. And a guarded prognosis is advised in cases where there is much dilatation of the anterior wall of the sac; the flow of tears often continuing after the largest probes have passed, owing to the inability of the stretched fibres of the orbicularis to produce the compression necessary to expel the contents of the sac.]

I have for nearly ten years practised the dilatation of the natural passage exclusively on the plan of Bowman, with but slight

modifications; the idea, however, on which I have proceeded, or rather to which the course of my observations has conducted me, is different from that which appears to have floated through the mind of the great reformer in the treatment of diseases of the lachrymal duct. I am of opinion that *so great a dilatation as is sought to be effected by the use of probes No. 5 and No. 6 of the Bowman series, is neither necessary to the restoration of the normal functions, nor devoid of danger.*

It is unnecessary; for during the last three or four years I have seldom used No. 5 and never No. 6, and have still effected many lasting cures. All this time, too, I have hardly had a case of obliteration of the canaliculus or nasal duct, following the probe treatment. It is the larger probes, in my opinion, which are apt to cause laceration and consequent closure of either of these places, even when properly introduced.

Let us consider what takes place *when the probe is passed through the lower canaliculus.* About 3" of it cannot be slit up, at any rate cannot be converted into a permanent open channel. The aperture of this portion is smaller than the diameter of No. 5. Granted that by the gradual passage from small to large probes we may even get in No. 6 without danger of disturbing the epithelial layer, we are by no means sure of not rupturing or lacerating the canaliculus. The line of direction of the lower canaliculus is set at an acute angle to the line of direction of the lachrymal duct. When the probe is raised, the end of the unslit portion must be dislocated and stretched in proportion to its length and the tenacity with which it encloses the probe which has been introduced. Neither the outer nor the inner end of the unslit portion admits of more than a moderate change of position, the inner end especially being a part where rupture cannot always be avoided, no matter how slowly the probe is raised. It is this rupture which I believe lies at the bottom of the subsequent closure. Take a case where No. 6 has been easily introduced, and where the intervals

[Whole No. 2142.]

\* Archiv für Ophthalmologie. Bd. 14. Abth. 3. S. 267.  
Vol. III.—No. 7

between the treatment are gradually allowed to grow longer, suddenly it will be discovered that no probe, or at most only a very small one, can be introduced. In this connection I should say that, in some cases where even No. 1 could not be passed, I have succeeded in introducing the conical probe, carefully observing the proper line of direction, and have then gradually been enabled to resume the use of the larger probes. I cannot, however, state whether entire occlusion did not in time ensue, it happening unfortunately that the patients absented themselves as soon as they ceased to be annoyed by lachrymation. If I could not succeed in this way, I slit up the upper canaliculus and probed through this.

I am not sure, but am fearful that the large probes may cause mischief in the nasal portion of the canal, the capacity of which is known—in the majority of cases—to be hardly above No. 4. When, after the removal of the probe, the patient has bled at the nose, I consider that there is a tendency to cicatricial contraction or obliteration, and I omit probing for several days. If the bleeding takes place at the first visit, I can only account for it by supposing the probe to have been improperly introduced or removed. And I may here say that I accomplish the latter manœuvre after fixing the head, and nearly as slowly as the former. If at a subsequent visit, and after the use of a larger probe, I get bleeding, I am apt to suspect that the size of the probe has given rise to a loss of epithelium or to rupture. If I have begun to use a larger probe, and get on withdrawal a feeling as though it were held fast by the passage, I interrupt the treatment for several days, and take next time a smaller probe. I sometimes use Nos. 3 and 4 and a rather slight No. 5, slightly bent and made of hardened caoutchouc, and these effect a passage in many cases where silver ones of the same size could not be introduced without danger of injury.

*Probing through the upper canaliculus* I have only employed in cases where the lower had grown up, after treatment by me or by others. Both the slitting up and the proper introduction of the probe into the sac present here, I think, extra difficulty, particularly when the brows are unusually prominent. In such cases it is not always easy to put the canaliculus on the stretch in the proper direction, that it may be correctly slit up; still less to keep it stretched and pass the end of the sound downwards and inwards along its anterior lower wall. But raising the probe is not only

easier but less dangerous, inasmuch as the unslit portion of the canaliculus lies at a very obtuse angle to the line of direction of the lachrymal sac. Here, too, should the relative size of the probe be too large, we incur the danger of disturbing the continuity of the epithelial layer and rupturing the canaliculus. If we turn the probe without being certain that its end has reached the extremity of the canaliculus, we may pierce its walls and thus endanger the integrity of the lower canaliculus. The difference between this method and that of Anel consists in the slitting up of (the outer half of) the canaliculus; it allows the introduction of larger probes with much less violence, and consequently much less danger of catching the probe in the inner wall of the sac. The larger probes are more readily guided, more easily handled, and run less risk of penetrating the tissues than the fine ones which Anel was obliged to employ.

I have never practised the *method of Weber*.<sup>\*</sup> When he published it I was trying that of Bowman, and in the course of this trial I became gradually convinced that the thing to be gained is not so much the smoothing out of the sides as the restoration and maintenance of a canal large enough to interpose no invincible obstacle to the fluid sent down by the action of the orbicularis. Is it to be supposed that Anel never wrought a cure with his thin probes? A reliable old practitioner, Dr. Schmalz of Pirna, assured me that he got his best results by the simple insertion of a thread (the method of Ad. Schmidt). Too much stress is not to be laid on the analogy with the urethra; for there we so often have an opportunity, by subsequent autopsy, of testing and confirming the correctness of our theories as to the position and consistency of the stricture, as to accumulate a certain amount of sound theoretical knowledge, bearing upon subsequent soundings and their significance. But in the case before us we rarely have a chance of gaining anything by dissection, while a knowledge of the relation of such results to our previous observations of the case, and to the action of caustics and probes, will

<sup>\*</sup> A. f. O. Ed. viii. Alth. I. S. 94. [Instead of Bowman's probes, Weber proposed the employment of elastic urethral bougies of small size, stiffened with a central wire. In tight callous strictures to which this treatment was inapplicable, he employed conical metallic probes, the thin portion of which was constructed of hard, the thick of soft silver, and thus prepared the way for the introduction of the bougies. He moreover slit up the canaliculus as far as its entrance into the lachrymal sac, and the entrance to the sac itself, dividing the ligamentum incisale subcutaneously. He made his approach through the upper canaliculus.—H. D.]

long be a consummation devoutly to be wished for. The urethra is surrounded by soft, more or less elastic tissues; the nasal duct by bone. What becomes of the circulation in the mucous membrane imprisoned between the bone and the probe or bougie? What state of things supervenes directly on such imprisonment? May it not happen, during the passage or withdrawal of probes that enlarge after introduction, that the union between the mucous membrane and the bone gives way more readily than the adhesion between the probe (bougie) and the mucous membrane? The diseases of the urethra generally result from local irritation; the mucous lining of the lachrymal sac is hardly accessible to aught else than the tears. It is a well-known fact that even in conjunctival blennorrhœa (acute, chronic, of the new-born, or of adults) it is seldom we see an invasion of the mucous membrane of the lachrymal sac. Nearly all diseases of the lachrymal sac are to be traced to a chronic catarrhal inflammation of its mucous lining, and this in the majority of cases is doubtless connected with extended disease of the mucous membrane of the nose or throat, with scrofula, an injudicious course of life, and unfavorable external circumstances. In relapses of chronic catarrhal inflammation, are we to consider insufficient local treatment the invariable, or at least immediate cause? May not new inflammation and new stricture arise in a lachrymal sac that has undergone general dilatation? I regard probes (and bougies) as a single and not the only remedy in chronic catarrhal affections of the mucous lining of the lachrymal sac. I have made but slight trial of the injection of medicinal agents, such as moderately strong solutions of sulphate of zinc or nitrate of silver; intend, however, in future to apply them more frequently with the probe-syringe recommended by Wecker (*Maladies des Yeux*, Paris, 1868, T. i., p. 890). I expect but little from them.

From the preceding the reader will readily conclude that I have been unable to give in my adhesion to *incising the strictured portion*, and subsequently dilating. The instrument designed to accomplish this can hardly be introduced and manipulated without simultaneously injuring parts which it was not intended to touch. In reply to authors who claim to have thus succeeded, I can only state that I have every reason to be satisfied with the treatment proposed by Bowman—with the exclusion of the larger probes. The results, however, which have induced Warlemont (*Ann. d' Ocul.*, T. ix.)

to eulogize the method of Stilling\* (Casel, 1868) should lead to its farther trial.

In *fistulæ of the lachrymal sac*, I never introduce the probe through them, but through the slit-up canaliculus. It is well known that fistulæ which have been used a long time for the introduction of probes, pieces of catgut, &c., are the more difficult to close. The earlier such an opening is closed, the pleasanter and the better it is for the patient.

My recent experience enables me to again recommend in the most emphatic manner, in cases of *inflammation of the lachrymal sac*, a closely fitting pressure bandage, either alone or after slitting up the canaliculus, should that still be possible. It is true success is not constant, that is where the inflammation is advanced, but in such cases it does no harm, and saves the other patients much pain and the inconvenience of the spontaneous or artificial opening of the anterior wall. During the past year I have exhibited three cases of brilliant success among out-patients at the clinique, and had, too, only one failure.

In closing these remarks, I will take occasion to once more allude to the advantages which the plan of Bowman, employed as I have indicated, possesses over other methods. With proper patience and perseverance it surely attains its ends, provided the carrying off of the tears is impeded by no other obstacle, such as swelling of the mucous membrane of the lachrymal sac, with or without stricture; and we shall hardly ever harm the patient by inducing obliteration of the canaliculus or of the nasal duct. We promise him that he will have but little pain, and keep our word. But we need to secure ourselves from unexpected movements of the head, and make the patient sit with his head supported from behind. And, with hardly an exception, patients consent to this plan of treatment, as soon as circumstances admit of their visiting the surgeon daily for a few weeks. Hardly enough stress can be laid on this, when we consider that it is in our power to conduct a rational and safe course of treatment, at a time when the cicatrization of the mucous membrane has but slightly advanced. Even when a fistula has already formed, we can predict its clo-

[\* Stilling incises the strictured portion by passing a knife of suitable form through it, and on withdrawal cuts in three or four directions, so as to make the division more complete. No after-treatment is used. He says:—"As soon as the bleeding ceases, the eye, which a few minutes before swam in tears, becomes bright and clear; to the great joy and astonishment of the patients, who often at once state their vision to be considerably improved."—H. D.]

sure, and with it the removal of the facial deformity, in the simplest manner and in a short time. But the greatest advantage lies in the fact that, in case of a relapse, which may occur after every method, not excepting the obliteration of the lachrymal sac (a thing not always quickly accomplished), we have the way open for the introduction of the probe, and that patients living at a distance can be taught, or have their friends taught, how to introduce the probe, thus enabling us to prosecute the cure at our convenience.

#### MEDICINAL PLANTS INDIGENOUS AT PARÁ, USEFUL IN DYSENTERY AND DIARRHŒA.

By J. F. DA SILVA LIMA, M.D.\*

I WAS quite flattered recently by receiving from an eminent physician of Pará, Dr. Francisco da Silva Castro, a valuable donation of three remedial agents of that Province, which have proved efficacious, in the practice of that learned colleague and diligent observer, against the bloody-flux that prevailed in the city of Belem (Pará) the past year.

Learning that an epidemic dysentery prevailed in Bahia, Dr. Silva Castro with laudable generosity hastened to furnish us with these remedies, in order to give to our many sick the advantages derived from his own experience, and to afford us an opportunity of submitting to clinical tests the virtues of these agents in the treatment of this formidable disease. The occasion, however, had passed, by the subsidence of the epidemic, when Dr. Silva Castro's offering came to hand. I hope, nevertheless, to avail myself of it in sporadic cases of this disease, not infrequent amongst us, and in due time to publish the results of the trial, should they appear likely to become useful to the profession.

But as no opportunity has yet arisen, I deem it not improper to state what these agents are, with the information received from our distinguished colleague of their effects, and his modes of administration.

I. *Marupá* or *Marupá-miri*.—On this plant Dr. Silva Castro has favored me with the following extract from his unpublished work:

"Common name—*Marupá* or *marupá-miri* (Pará, Amazons).

"Scientific name—*Simaruba amara* Pa-raensis—belongs to the family of Rutaceæ. A small shrub.

"Part employed—Bark of the root.

"Action, or virtues—Tonic; and, in larger doses, emetic.

"Dose and formula—Internally; one or two drachms in decoction with a pound or more of water.

"Remarks.—Very useful in diarrhœa and dysentery; and to be recommended."

According to our colleague, the *marupá* is not only efficacious but quite infallible in the treatment of diarrhœa and dysentery; and was the therapeutic agent relied on when these diseases raged in Pará in the beginning of the year 1868, as may be seen by the following extract from his Report as Inspector of Public Health to the President of the Province. "It should be stated that the remedy most constantly used to combat this disease (dysentery), and which gave the best results, was the bark of the root of the *marupá-miri* (*simaruba amara*), one drachm to a pound of decoction, of which an ounce every two hours was given until the disease yielded—a result generally obtained in four or five days from the first administration. A diet of warm simples from chicken, fresh meat, or rice alone, materially aided recovery.

II. *Pajurá*.—Concerning this Dr. Silva Castro writes:—The *Pajurá* is the nut or seed of that name. It is derived from a large tree, which grows in low or wet lands on the borders of rivers, lakes, &c.; but I have never seen it, and therefore do not know to what family it belongs. The fruit is large and has a delicious flavor. The nut is given in powder, in scruple doses, three or four times a day in any vehicle, and is decidedly efficacious. The Indians and the people of the interior use it with great benefit. I tried it in two refractory cases, and obtained good results."

III. *Pereiorá*, or *precious bark*.—In relation to this plant Dr. Silva Castro sent me a copy of the following passages from Martius (*Systema Materiæ Medicæ Vegetabilis Brazilianensis*);—"Laurineæ. *Pereiorá*," or *precious bark*, Rio-Negro (*Mespilodaphne pretiosa*). The bark of this equally great forest tree, celebrated by the name of *canelilla* among the inhabitants of Orinoco, aromatic in flavor, warming and sweetish, corresponds to true canella. Its odor is that of sassafras, a mixture of canella and roses. It contains, principally in the inner bark, a yellowish ethereal oil, heavier than water, and comparable to the oil of canella. Medicinal value is accorded to it principally with the bark of sassafras; and its use has been skilfully adjusted in decoctions, infusions, and baths, for many diseases, as, for

\* Gazeta Medica da Bahia, Jan. 15, 1869.

instance, nervous debility, œdema of the feet, chronic catarrh, dropsy, gout, &c.

Although Dr. Silva Castro has not full confidence in all the vaunted virtues of *Pereiorá*, he nevertheless affirms that a tea-like infusion of the scraped bark, in the proportion of one ounce to a pound of water, is useful in diarrhoea and dysentery; and that the Indians of Rio-Negro give preference to the fruit, dried and given in powder. Our colleague made some trials of the infusion with beneficial results.

Having shown to my friend, Dr. Bomfim, Professor of Botany in our Medical Faculty, the three specimens sent from Pará by Dr. Silva Castro, and his letter, the Professor had the goodness to send me the following note which, for the elucidation of this point in our National *Materia Medica*, I now transcribe:

*"Marupá-miri.*—This is the *Simaruba Paraensis*, mentioned in eighth edition of the Formulary of Dr. Chernoviz, and in the *Materia Medica* of Dr. Beirao, as possessing the same medicinal properties as *Simaruba Officinalis*.

"Both plants belong to the family of *Simarubaceæ*, established in 1808 by Richard Pae, reduced by Adr. de Jussieu in 1825 to a simple species of *Rutaceæ*, and lately elevated to the rank of a botanic family by Lindley and the principal botanists of the day.

"The *Simaruba Officinalis* was introduced into Europe in 1813, having been accounted for by the inhabitants of Cayenne and Guyana as a *specific* in dysenteric affections. Its valuable powers, against such diseases, were confirmed by the celebrated botanist Antonio de Jussieu during the epidemic which prevailed in Paris in 1809. Since that time it has been proclaimed, and received, as an anti-dysenteric of the first class.

"To its more active tonic properties are due these remarkable results, as well as those obtained in cases of debility of the system. It is fit, however, to state that its use ought to be advised in dysentery, only after satisfying certain general rules—after, for instance, subduing the gravel when it exists; else the perils of the disease may be augmented by exciting intense local inflammations.

"'Useful in advanced stages of dysentery and diarrhoea,' say Drs. Royle and Headland in their *Materia Medica*, fourth edition, 1865, page 356.

"As to the therapeutic uses of *Pereiorá*, the specimen sent by Dr. Silva Castro, and the clause in his letter commencing 'the

tea-like infusion of the bark,' &c., appear to me to give a sufficient idea of the plant and its properties against dysentery. An examination of the leaves proves it to belong to the variety *longifolia* or *angustifolia*.

"The fruit of the *Pajurá* shows it to be of the family of *Lauraceæ* or *Laurineæ*. It is dry, but drupelike, and within the nucleus is enclosed an embryo destitute of endosperm, similar to the embryo of the *Persea gratissima* (abacate). This embryo, reduced to powder, is that experimented on by Dr. Silva Castro, as well as that referred to in his letter.

"The *Pajurá* and the *Pereiorá* owe their good effects in dysentery and diarrhoea to an aromatic principle, that is, to an essential oil which generally exists in plants of this family."

I give publicity to the preceding statements concerning these three important remedies indigenous on the shores of the Amazons, not only in consideration of the eminent colleague who honored me with this valuable consignment, and to whom science already owes numerous interesting contributions to our National *Materia Medica*, but equally to enable other practitioners, hitherto unacquainted with these agents, to make a trial of them in dysentery and diarrhoea, and thus, by adding the results of their experience to those obtained by Dr. Silva Castro, to establish definitely the therapeutic value of these remedies in such diseases, and thence to spread abroad their adoption from a limited locality where their usefulness has rendered them a necessity.

## Reports of Medical Societies.

OBSTETRICAL SOCIETY OF BOSTON. SECRETARY,  
HOWARD F. DAMON, M.D.

DECEMBER 5th, 1868.—The society met at the house of the President, Dr. Putnam, at 8, P.M.; the President in the chair.

CASE I.—*Puerperal Convulsions.*—Dr. Abbot reported the case.

The patient was a young, healthy, robust lady, pregnant for the second time, having aborted at an early period in her first pregnancy. She had been remarkably well during her second pregnancy, with the exception of being badly poisoned with ivy, two or three weeks previous to confinement. She awoke early in the morning and complained of intense headache, labor not having commenced, and had several convul-

sions. Labor came on during the forenoon and lasted three or four hours. The patient was seen by Dr. Abbot in consultation two or three hours after confinement, which was premature, at the seventh month. She had three or four convulsions during his stay of three hours, but was conscious enough in the interval to recognize her husband. The patient was bled to the extent of a pint with marked relief, as she was observed previous to a convulsion to put her hand to her head as if in pain. Subsequently, slept for a time, but the convulsions returned and were kept in check by the constant administration of ether through the night. No urine could be obtained for examination. The patient made a good recovery.

CASE II.—*Puerperal Convulsions*.—*Albuminuria*. Dr. Abbot reported the case. Parturition took place in this case, Nov. 30th,

TABLE.					
Time.	Reaction.	Sp. Gr.	Albumen.	Pus.	Casts.
Dec. 6th. Unknown.	Acid.	1011	Large Quantity.	Present.	None.
" 7th. Evening.	"	1019	Diminishing.	"	A few hyaline.
" 8th. A.M.	"	1016	"	"	None.
" 9th.	"	1021	"	"	"
" 10th.	"	1016	"	"	"
" 12th.	"	1011	Scanty.	"	None. Some blood.
" 14th.	"	1016	Nearly as much as at out set.	Increased.	None.
" 17th.	"	1026	Very much less than at any time previous.	Very little.	Very heavy deposit of amorphous urates.
" 18th.	"	1017	No albumen.	None.	No casts. No blood.
Albumen steadily decreased from 6th to 14th, then suddenly increased. Pus " " " " " "					

between 12 and 1 in the morning. The patient had been unusually excited, tossing about the bed with great violence during the labor; and ether was given freely. There were no convulsions before the birth of the child, and the ether did not check the expulsive action of the uterus. The next morning there was intense headache, and a

convulsion at 10, A.M. The pain was in the left temple. Thirty grains of the bromide of potassium were given; and the patient came quickly under its influence, and slept six hours. She was said to have had oedema of the ankles, which commenced in July; the urine was found to contain a large quantity of albumen—about a third of the bulk of the liquid. Specific gravity 1016; it contained urates, and a considerable amount of triple phosphates, pus, and casts. The convulsion was not repeated. Milk has been secreted freely; and the oedema has disappeared. Dr. Abbot believed that if ether had not been administered, convulsions would have occurred during labor. The preceding table of examinations of the urine, made by Mr. E. N. Whittier, Medical House-pupil at the Massachusetts General Hospital, is interesting, as showing how rapidly the albuminuria may disappear in such cases.

Dr. Reynolds asked if such a patient is not liable to have more grave renal symptoms in subsequent labors.

Dr. Putman remarked that puerperal convulsions did not always depend on albuminuria; but were sometimes of an hysterical, epileptic, or apoplectic character.

CASE III.—*Albuminuria, Puerperal Mania*, &c.

Dr. Reynolds thinks it desirable to learn the character of the urine whenever a pregnant woman appears debilitated or anæmic, or when her nervous system is in an unusually excitable condition—especially if the patient gets but little sleep. He has repeatedly used in the case of such women, with most satisfactory results, the preparatory treatment upon which Mr. Clay of Manchester and Dr. Horatio Storer of this city have so much insisted before surgical operations within the abdominal cavity, the administration of full doses of muriate of iron for a month or more in advance, to which Dr. Reynolds commonly adds every evening, five grains of the extract of ox-gall, both as a mild laxative and a nervous calmant.

Dr. Lyman thought the ox-gall a most effective and admirable remedy, in from five to ten grain doses. He said it produces very soluble discharges, not unlike those obtained from the administration of sulphur.

Dr. Buckingham stated that he also used the ox-gall some years ago. He had seen many patients with convulsions. They were generally during their first labors, and many times they were hysterical convulsions.

CASE IV.—*Albuminuria during Pregnancy, Convulsion during Labor*. Dr. Buckingham

gave the following history of a patient whom he had attended several times in labor. At her previous labors, there was severe hæmorrhage after the birth of the child. On the present occasion she had passed over her expected time. Her feet and legs were œdematous, and her face was swollen; but she was in no pain, although she had hard work to get about. It was feared that she might have convulsions.

Large quantities of albumen and granular casts were found in her urine, two weeks previous to her labor. Her urine was very scanty, not more than an ounce being passed during twenty-four hours, on several days. The bowels were thoroughly cleared out, and gallic acid prescribed. She had intense headache subsequently, and supposed from the gallic acid. Dr. B. was called to the patient between one and two o'clock in the afternoon, and remained until after delivery. She then had pain in the abdomen, but the os uteri was rigid. At 5, P.M., she asked for ether, on account of headache. After it was given, she had pain in the loins, but fell asleep for five or ten minutes, when suddenly she started up and cried "Doctor!" and went into a state of perfect opisthotonos. There was severe convulsion. Since the labor one of her eyes is so affected that she could see but half an object. The magneto-electric battery was used, on this occasion, to cause uterine contractions; one pole being placed on the fundus, and the other over the umbilicus.

**CASE V.—Albuminuria; Convulsions after Delivery; Death.**—Dr. Cotting gave the history of a woman who had been the mother of a number of children, but was now again confined after eight years' interval; and whom he had seen in consultation. She was reported to him to have been confined at 2, A.M., after a perfectly natural labor. Her physician left her at 4, A.M.; suddenly and without premonition of any kind, she was seized with convulsions at 5, A.M. On examining the urine, it was found to contain large quantities of albumen and also casts. The convulsions continued almost without interruption, even when the patient was fully etherized. Ether had little or no effect upon their severity. She died early the next morning.

The subject of the administration of ether in labor was then discussed.

Dr. Abbot said he was opposed to the early use of ether, as it seemed to him in that stage to retard labor, as it sometimes did, in fact, in the advanced stages. He seldom gave it unless the patient asked for

it, and then not usually before the second stage, and in moderate quantity.

Dr. Parks asked the President if he was in favor of giving ether in natural labor.

Dr. Putnam said the objection most commonly made is that the labor is retarded. This is true—sometimes most remarkably—but on the other hand the labor is often indirectly facilitated and accelerated by its influence in quieting nervous irritation and promoting the secretions and dilatation of the soft parts.

A more serious objection, if well founded, is the alleged liability to be followed by hæmorrhage. In his experience this had not been confirmed.

In reply to a question Dr. Putnam stated that he had sometimes employed ether in the very first stages of labor advantageously and agreeably.

Dr. Reynolds is of the opinion that in not a few instances the removal of the acute suffering enables the patient to give increased aids by her own exertions, while there are now and then women of fine muscular development, with whom the moderate use of anæsthetics relieves the distress without lessening the expulsive efforts.

Dr. Buckingham thought that, in hysterical cases, ether interfered with the progress of labor. Dr. Lyman gave a very graphic account of a case, in which two quarts of ether were given to a hysterical young woman during labor, without quieting her turbulence.

Dr. Cotting reported a recent case in which turbulence increased, but labor ceased during three hours of administering the ether. Discontinuing the ether, labor went on; and the patient declared that the labor itself was more tolerable than the effects of the ether. This was not a solitary case of the kind in his experience. Ether was followed by other inconveniences besides hæmorrhage; retention of the urine was one. Still, he not unfrequently allowed ether in labor, though the advantages were less than originally anticipated.

Dr. Reynolds said that in certain cases of undilated os he believed the full administration of ether for a short time a most excellent plan. When not given expressly for this end, he prefers to use very moderate doses. There is a class of hysterical patients whom it is very difficult to tranquilize with ether.

Dr. Read thought that there were two classes of women who are met with in labor. One selfish, unwilling to suffer the pangs of child-birth, and with no thoughts of their

expected offspring, seeking only to be made unconscious of suffering at any risk. The other true mothers, who, while probably as ready to be relieved of pain, and desirous of obtaining as much relief as possible, still desire that relief in the safest and best way for both themselves and the child yet unborn. The first claim ether from the outset and clamor for it, the latter accept it as a boon, when it is the most proper time for its administration. He thought that when ether was administered from the outset, it had the effect to weaken the expulsive power of the pains, so that at last they do not force the child down at all, and resort must be had to instruments in cases when otherwise the labor must have been natural. He thought it was best to delay the administration of ether till so late a period in the labor that this effect could not happen. As, for instance, till the time when the head rests on the perineum.

Dr. Minot thought that most women wanted ether; he always gave it when asked so to do. He did not think it retarded labor.

Dr. Putnam then asked the opinion of the society in regard to the production of uterine hæmorrhage, in consequence of the use of ether.

Dr. Minot did not think hæmorrhage more frequent with ether. He said that the only patient lost by him, from uterine hæmorrhage, took no ether.

Dr. Lyman said that his faith had been shaken, during the past year, in regard to the use of ether in labor. He never lets his patients lose consciousness, and delays its use as long as the patient can be pacified without it. Dr. Abbot said that he had not seen any alarming hæmorrhage after the use of ether; but, nevertheless, he usually gave, where he had administered it, a dose of fluid extract of ergot, after the labor was completed.

Dr. Putnam then asked Dr. Sinclair to state his experience in regard to the production of uterine hæmorrhage, in cases where he had given ether.

Dr. Sinclair said that he always dreads the giving of ether, on account of the greater liability, in his experience, to hæmorrhage after its use.

Dr. Buckingham said that, on this point, he agreed perfectly with Dr. Sinclair; and had often been obliged to wait two or three hours with his patient for pains to return, which had been stopped by ether.

Dr. Parks asked Dr. Buckingham if he still retained his views in regard to the use of opium in labor.

Dr. Buckingham said that he did, and spoke of its use as advised by Dr. Murphy in the treatment of hæmorrhage. He gave a full dose at the outset, if he wished to stimulate. The dose, which would stop pain under ordinary circumstances, was only a stimulant in hæmorrhage, and if the prostration was great the dose must be large.

Dr. Ayer then spoke of the use of ergot. He uses Thayer's fluid extract; and thinks it is better, and more reliable, than the powder.

Dr. Abbot remarked that it is the general impression that it is important to have the powder freshly prepared. He had been informed, however, that most of the powdered ergot sold is ground in large quantities, and supplied to apothecaries who keep it on hand for an indefinite length of time, as its extemporaneous preparation is extremely difficult.

Dr. Cotting thought that the active properties of the ergot reside in the outer portions, or covering, of the fungous growth.

Dr. Ayer then reverted to the use of ether. He said that he seldom gives ether in the first stages of labor; but uses an enema of three grains of tartarized antimony. He had seen more secretion of mucus from the vagina, in consequence of this, than from the use of ether. It also hastens the first stage more than ether. He is satisfied that it produces a great deal of benefit. He uses the valerianate of morphia; since it is less exciting than some of the other forms in which opiates are given during labor. He always fears hæmorrhage where he uses ether in labor; and remains longer with his patient, where it has been given.

Dr. Sinclair then reported the following case, to which he had been called in consultation.

CASE VI.—Mrs. —, aged 21, primipara, strong and healthy in appearance; in labor over twenty-four hours, during which period she had three or four severe convulsions, for which ether was given. Dr. S. did not witness a convulsive paroxysm. The pains continued moderately efficient and the os uteri sufficiently dilated. Although the labor might have terminated safely, as to the mother, without artificial interference, he advised delivery by the forceps, for the reason that the fetal heart pulse had fallen to 105 in the minute. Instrumental delivery was easily effected, but considerable difficulty was experienced in the resuscitation of the infant. Mother and child did well.

Adjourned at 10, P.M.

Subsequent to the regular business of the

meeting, Dr. Sinclair exhibited Dr. Charles's cephalotribe and the *Retroceps* or *asymmetrical forceps* of Dr. Hamon, de Fresnay (sur Sarthe), which Dr. Sinclair believed to be, perhaps, the most handy and effective cephalotribe hitherto made.

Dr. Thierry-Mieg, a distinguished obstetrician of Paris, first directed the attention of Dr. Sinclair to the retroceps. Dr. S. has translated the following description of the instrument from an article by that gentleman in the *Journal des Connaissances Médicales Pratiques et de Pharmacologie, du 10 Mars, 1868*.

"The retroceps is an asymmetrical forceps; one of the blades is introduced on the left side, almost like the original forceps, and the other on the right, but the two branches, united, embrace generally over a quarter or a third of the posterior circumference of the head.

"From this arrangement, it results that the two blades of the retroceps are much more easily applied than those of the common forceps; and the branches are articulated without any difficulty, thanks to the ingenious mechanism with which the handle of the instrument is provided.

"The blades once placed and articulated, extremely moderate tractions are sufficient to cause the head of the fœtus to advance; and for this purpose, only one hand is needed, or even two or three fingers of the hand, when the head is retained on the floor of the perinæum, the most frequent indication for the application of the forceps.

"The secret of the remarkable facility with which the fetal head is made to advance by means of the retroceps, is explained, in my opinion, by the combination of the two following conditions:

"The first consists in this, that the pressure of the instrument, during traction, is exerted upon the part of the head situated in the posterior portion of the pelvis; this pressure tends, consequently, to cause the head to rotate under the symphysis pubis. Indeed, it is this rotation which constitutes by itself alone nearly the whole movement of the head after it has descended into the hollow of the sacrum.

"The second favorable condition is the possibility which the head preserves of turning a little in the blades, without ceasing to be firmly seized—a condition which allows it constantly to adapt its diameters most conveniently to those of the axis of the strait it is obliged to traverse.

"These two conditions are not so well answered by the symmetrical forceps. It is necessary that the branches of the latter

should grasp the head very strongly, and make with it a very solid union, so as not to slip upon it rather than cause it to advance.

"And on account, moreover, of this immobility of the head grasped in the instrument, it is necessary for the accoucheur to make tractions with the greatest care, in the curvilinear direction of the axis, so as not to draw uselessly, notwithstanding all the force he is able to exert.

"Supposing that he should succeed in following the direction of the axis perfectly, he will not, for all that, know how to impress on the head of the fœtus all the little movements in a lateral direction, of flexion and of deflexion, which alone permit it to accommodate successively its diameters in the best manner possible to the more or less oblique and narrow diameters of the canal that it is forced to traverse.

"Hence the resistance that the ordinary forceps is obliged to overcome by force, and that the new instrument spares to the accoucheur.

"Another advantage of the retroceps, and a valuable one, is that it may be introduced, articulated and the necessary tractions made, without changing the position of the patient in the bed. How often is the physician embarrassed, considering himself justified, according to the rules of practice, in applying the forceps, but hesitating, to avoid if possible, for the sake of the poor woman and the interested attendants, the formidable preparations which this application demands. It becomes necessary, in fact, to place the patient across the bed, to have some one hold the head and shoulders, two assistants who will evince sufficient courage to withstand the sight of blood and the operation, each one to hold the flexed legs of the patient; recollecting the fearful length of the classic forceps, the difficulties which one sometimes encounters in articulating them, the force which may be necessary to exert in the tractions; are these not sufficient circumstances to cause the physician to hesitate before revealing to the family the necessity for the application of the instrument?

"With the retroceps, matters are much more simple; the head, let us suppose, is retained on the floor of the perinæum, the resistances are too great or the expulsive force is insufficient, the accoucheur waits the wished-for time, an hour, an hour and a half, &c. He arrives at the conviction that the application of the forceps is necessary. Silently he makes ready. No assistant, no change in the position of the

woman are necessary. The introduction of the blades, for which it is not indispensable to know the exact position of the foetal head, is made with great ease, the articulation equally so. To do this, it is not necessary to remove the bedclothes. Then slight tractions with one hand or one or two fingers of the hand, as already said, suffice to make the head advance, and if before the head is born the operator wishes to disarticulate the blades, he can do so without the least trouble, for it is necessary only to raise a little hinge adapted to the handle of the instrument.

"The retroceps can, moreover, be applied equally well in women confined on their left side *à l'anglaise*. Furthermore, backward and forward tractions, while the head is yet high up, are at the same time favored by that position.

"Finally, it may be added, that the retroceps is an instrument light and small, scarcely weighing 500 grammes, hinged so that it may be doubled up, placed in a little leather bag and easily put in the pocket. This is an advantage not to be lightly regarded by the practitioner."

## Bibliographical Notices.

*Recovery from the Passage of an Iron Bar through the Head.* By JOHN M. HARLOW, M.D., of Woburn. With a plate.\* Read before the Massachusetts Medical Society, June 3, 1868. Boston: David Clapp & Son, 331 Washington Street.

This paper, which is included among the Publications of the Massachusetts Medical Society, has been re-published in pamphlet form, and is for sale at this office.†

For a couple of years during the last decade, the attention of visitors to the Museum of the Medical College, in Boston, was attracted to an iron bar about three and a half (3½) feet long, and about as large round as a crow-bar. This object had an inscription carved upon it, from which inscription, and from the verbal statements which were given to satisfy the curiosity aroused, it was learned that the bar had been driven through the head of a man, by the accidental explosion of a charge of blasting powder, and, that this man, so far from being instantly killed by the injury, had recovered from its effects, and was actually walking on this planet, attending

to the ordinary affairs of life. Such was the outline of a case which has become of classic celebrity.

The physician who attended the patient whose cerebral organism had been comparatively so little disturbed by its abrupt and intrusive visitor, was Dr. J. M. Harlow, the writer of the pamphlet we are noticing, and who reported the case in the Boston Medical and Surgical Journal, Vol. 39, No. 20. In a foot note to the present pamphlet Dr. Harlow says:

"Soon after the publication of this case in the Boston Medical and Surgical Journal, in November, 1848, I received a letter from Dr. Henry J. Bigelow, Professor of Surgery in the Medical Department of Harvard University, requesting me to send Gage to Boston, generously proposing to defray his expenses and compensate him for loss of time. Gage being quite well, and the hole in the top of his head entirely closed, accepted this proposition, and remained in Boston, under the observation of Prof. Bigelow, eight or nine weeks, where he was examined by many medical men, Prof. Bigelow being thoroughly convinced, at a time when the accident had very few believers either in the medical profession or out of it, that the lesion was as represented—that the iron had traversed the brain and cranium as stated. With my concurrence he reported the case, with illustrations, in the American Journal of the Medical Sciences for July, 1850."

Dr. Bigelow having thoroughly investigated the case, and satisfied himself of its genuineness, finally succeeded in forcing its authenticity upon the credence of the profession in this city, as could hardly have been done by any one in whose sagacity and surgical knowledge his *confrères* had any less confidence. But for his persistent efforts, we may assume, with no disrespect to Dr. Harlow,\* the first report of the case might have slumbered unnoticed in an old volume of this Journal, and never have secured its rightful place in the annals of surgery—never have been accepted by the medical public, as a record of important facts, to be relied upon by the physiologist and the metaphysician. It was Dr. Bigelow, also, who had the inscription made on the tamping-iron,† and who persuaded the patient to allow it to be deposited in the Museum of the Medical College. As we learn from Dr. Harlow's pamphlet, the ac-

\* Reproduced as a frontispiece to the present number of this Journal.

† See advertisement.

\* The accident happened, it should be remembered, more than twenty years ago, when Dr. Harlow did not reside in this State.

† An implement used in blasting. It was subsequently reclaimed by the patient.

cident occurred in Cavendish, Vermont, on the 13th of September, 1848. The subject of it was residing in California when he died, which was on the 18th of May, 1861; between twelve and thirteen years having thus intervened between the date of the injury and his decease. During a short period before his death he had several severe convulsions.

Dr. Harlow had the enterprise to obtain the cranium and the iron-bar; and having exhibited them at the last annual meeting of the Massachusetts Medical Society, has most generously presented them to the Museum of the Medical Department of Harvard University. He also gives his obliging assent to our using the blocks which furnished the delineations in his paper, as it appeared in the Publications of the Massachusetts Medical Society, and as it is now published in pamphlet form. It is thus that we have come by the woodcuts in the frontispiece of our present number. The pamphlet describes the original accident, and the wounded parts from the outset; also the course of the case, and the treatment till recovery. It further gives a sketch of the subsequent history of the patient; and concludes with a description of the external and internal *post-mortem* appearances of the cranium.—Ed.

## Medical and Surgical Journal.

BOSTON: THURSDAY, MARCH 18, 1869.

In *The American Journal of the Medical Sciences* for January the leading article is by Dr. Samuel Jackson, Professor Emeritus, &c. &c., on cases of "Double Consciousness."

The most marked of the four cases described was that of a young man who had had violent convulsions, of what precise nature we are not told. For two days after his worst attack he remained in a state of great prostration, with occasional delirium. "About the third day his attendants remarked that his mind was engaged, as it were, in the recital or narrative of imaginary scenes taking place in New York,\* where he supposed himself to be in company and holding conversation with, and finally paying particular attentions to a young lady. He imagined he had a rival for her favors, and entered into a quarrel, which ended in a challenge and a duel. This was the outline of a complete novelette, with various adventures that are omitted, composed at periods of about half an

hour each during three days, and it was observed that when the story was resumed it was in immediate connection with the part where it had ceased. . . . During this period his eyes were open, and to all appearances he was awake and conscious; but when he would suddenly cease, and was asked what he had been doing, he insisted that he had been fast asleep. He was utterly unconscious of anything that had occurred." He ultimately recovered.

We follow Dr. Jackson when he says that the name of double consciousness as applied to such cases as the above is a misnomer; and when he remarks that the main fact is the introduction of a new set of ideas and trains of thought, which ceased at once after different intervals. He, however, goes on to say that through consciousness we have a knowledge of our own existence, and of the world without; that consciousness reveals the operations of the intellectual faculties. Here we must discriminate a little. We subscribe to the ideas of Bishop Berkeley so far as to assume that we are cognizant of the external world by inference—intuitive, of course—derived from our perceptions, and those in turn developed by our sensations; though the inference may be "short, sharp and decisive," as in the experiment suggested by Dr. Johnson of violent contact with a stone. We define consciousness, therefore, as the faculty which gives us, or rather, perhaps, which *is*, the knowledge of our existence and of our mental operations, but which does not of itself alone reveal to us the external world. The consciousness of our mental operations is also—we take it—limited to those of the present instant. But, we have the memory of an act or state of consciousness at the instant preceding the present one; as we have the memory of an act or state of consciousness twenty years previous.

With these brief propositions as to the nature and office of consciousness before us, we glance again at the case of the young man mentioned by Dr. Jackson. He was conscious of mental operations which for the most part corresponded with the facts of his external life as observed by those around him. At periods of about half an hour each, during three days, he was conscious of certain mental operations which did not correspond with the facts of his external existence. It was manifest that those mental operations—of the diseased as well as of the comparatively healthy intervals—actually took place. His consciousness of them, therefore, we have no reason to suppose to have been perverted; though the memory failed to report the statements of consciousness from the diseased to the comparatively healthy condition, and *vice versa*. Where, then, was the lesion?

We have at the periphery, so to speak, sensation. Further within the enclosure we place

\* He was in reality in a distant place.  
VOL. III.—No. 7B

perception. No less central, at least, are thought and memory. But, in the very citadel of the mind, we must at all events locate consciousness. The cerebral disorder, in the case before us, may have made itself felt, perhaps somewhere in the region occupied by memory, perception and sensation. The mental operations, in the abnormal intervals, seem to have been logical enough in their sequence, so far as we are informed; but would appear to have been somehow supplied, from moment to moment, with wrong premises to start from. This is as far as we can get. But, as we have said, we agree with Dr. Jackson that the term double consciousness, as applied to the phenomena in question, is a misnomer. We should conjecture that the condition of mind indicated by them was allied to somnambulism—was something like somnambulism developed out of the waking state, instead of occurring as an episode of sleep.

Curiously enough, we had just finished writing the few words above, and had laid aside the manuscript, supposing we had done with the question of so-called double consciousness, when we took up *Little's Living Age* for February 20, 1869, which was lying with leaves uncut on our table. Glancing at the "Contents," we saw the caption "Disconnected Memories." Turning to the article indicated (which was from the *Spectator*), we found in it an account of a case somewhat analogous to the one described by Dr. Jackson, and which is spoken of by the writer (who signs himself B. K. R.) as a sort of *somnambulism*.

The case, however, we have been considering differs from the one related by B. K. R. in one respect. In the latter, the notions of place and the perceptions of surrounding objects were correct; while in the former the true perceptions of situation and external objects were in abeyance, and were replaced by imaginary ones. There is similarity between the two cases in the phenomena of disconnected memory, and of departure from the ordinary *morale*.

The particular case to which we have alluded, as among those mentioned by B. K. R., is thus described:

"The instance of what might be called 'two lives in one' occurred in a French lady of middle age, the wife of a lawyer in Normandy. In appearance she was robust, but had a heavy look about the eyes, and was of a highly nervous temperament. For about a year before the time I met with her she had been subject to what the physicians (who regarded her as a psychological curiosity) called fits of somnambulism. She would close her eyes at any hour of the day or night, and open them shortly after in a totally different state of consciousness. On one occasion, when her husband did not return from a journey at the expected hour, she became anxious, and sent a servant to the town to inquire if there were letters from him. Soon after she fell into the abnormal state which was easily brought on by excitement or

anxiety. During its continuance her husband arrived at the chateau. She welcomed him joyfully, inquired about his journey, ordered refreshments for him, &c., but after he had quitted the room she soon awoke as from a dream, and eagerly inquired if the servant had returned and what tidings he had brought about her husband, entirely unconscious of having just seen and conversed with the latter—indeed, she could hardly be convinced of the fact. In each state she always went back immediately to the moment at which she had quitted that state, whichever it might be, taking up the thread of her life there and recollecting what had passed during its continuance, while the intermediate period seemed blotted out of her memory for the time.

In her dream state, if it may be so called, she would talk in the *patois* of her native village (which she carefully avoided at other times), and would sing very sweetly provincial ballads, which in her normal state she could rarely be induced to do by her friends, being excessively timid and nervous. Her senses while in the dream-state were quite alive to all the objects around her; she could even use her needle, and on one occasion she noticed a rent in the soutane of the priest and mended it very neatly—though when she awoke she would scarcely believe that it was her work, not having the slightest recollection of the circumstances. In many respects she seemed to return almost to the character of childhood, doing many incongruous things; for instance, she would want to walk out, or order the carriage in the middle of the night without due cause—was wayward and petulant if contradicted, and so little under the control of reason that it was considered unsafe to leave her with servants only. To her husband or the priest she would submit immediately.

When under the influence of this sort of somnambulism, her state appears to have somewhat resembled that which I have since heard may be induced by mesmerism. Its peculiarity consisted in the accuracy of the impressions made on her by outward objects, whilst all that happened, after vanishing like a dream, was distinctly remembered the next time she fell into this waking sleep; thus she lived two lives, each with a memory of its own, but linked together by recognition of the same persons and objects.

It should, however, be observed that these two lives were not simultaneous, but alternated with each other."

The "*Spectator*," in reviewing the case of B. K. R., makes the following remarks:

"It is, as we understand it, the case of a lady with what we may call a *forked* memory—i.e., two distinct states of memory, each of them grafted on to a common stock dating more than a year previously, but growing separately since that time. This, we say, is the construction we put on B. K. R.'s account of the Norman lady's case; though he describes it as two quite distinct and alternating states of memory, 'but linked together by recognition of the same persons and objects.' She tells us indeed that each memory, both the 'normal' and the 'abnormal,' went back straight to the last moment when it was interrupted by the transition to the other state. But this seems to us to imply that *both* went back to the time before the frac-

ture took place. If she recognized her husband, and servants, and house, and furniture, and remembered how to sew and sing, &c., in the 'abnormal' state, as she did, she clearly had a good stock of experience at her service, gathered from the time before her disease began. She could not have known her husband without remembering her marriage, nor her songs, probably, without remembering something of the time when she learned them, &c. . . . We suspect that both states were really abnormal, although only one of them seemed to change the lady's character and to impress upon it a more childish and less self-conscious aspect—that there had been, when she was first seized, some virtual untwisting of the thread of her life, one of the untwisted fibres connecting it with the condition in which she seemed most like herself, and another with the trance-like condition described by our correspondent, in which she lost her usual self-conscious timidity, her consideration for others (excepting her husband and the priest), and became wayward and wilful."

These suggestions seem to us sound, except that we do not like the term "forked memory." That expression implies two lives of recollection running synchronously back to a common point of departure. The specific term—alternate memories—would perhaps aptly designate the two cases we have been considering; while the general denomination—disconnected memories—would classify them with some other instances of aberration of the faculty of recollection.

We have reason to believe that some of our readers are disturbed by the discussion of the day on cerebral physiology and pathology; they seem to fear that we shall be led into the vagaries of materialism. We see no ground for apprehension on this head. All so-called knowledge is more or less a matter of inference, and is liable to error, except that which comes from consciousness. Even a mathematical demonstration, as being liable to inaccuracy, is less certain than the declarations of consciousness.

Your consciousness of your personal identity and of your mental operations are pure knowledge which can never err so long as you have the *mens sana in corpore sano*. Though disease distort the mental vision, nothing can take from the sound man the knowledge that the *ego* is one and indivisible. No matter how many modes of manifestation—under the names of reason, memory, perception, and so forth—are ascribed to the mind, the *ego* in which they inhere remains the one indivisible self; and it is at least probable that what we call the mind, acts as a whole in the employment of each and all its so-called faculties. In like manner, therefore, it matters nothing if the mind use the entire brain in the performance of each and all its functions, or if one faculty is manifested and developed by the use of one portion of the cerebral nerve mass, and another faculty by the use of another portion. And, conversely, it signifies not

at all, if it be proved that a lesion of a certain portion of the brain impairs or destroys one mental faculty without injuring other faculties. The statement that this or that mental power or function resides in this or that part of the brain, is not necessarily more than a figure of speech. In our opinion, the encephalon is only the centre of a telegraphic system, as it were, by means of which the mind communicates with the rest of the body, and with the external world. Even if Phrenology had proved its claim to be a science, and had shown that the brain was divided into special districts, for each faculty, sentiment, appetite, the statement that the latter were merely attributes of the one central being, would have been by no means invalidated, and the well-established principles we have re-stated would have remained intact. Let the scalpel, then, dissect the nervous fibres; the microscope search out their intimate structure; the chemical re-agent analyze their composition; and let such explorations tell us if they will that every act of thought involves a cell growth and a cell decomposition, with the expenditure of a certain amount of phosphorus. What then? Every inference, founded on these or other investigations, which comes in collision with the revelations of consciousness, falls to the ground. For, we repeat it, that is the only mental faculty which is the source of unerring knowledge.

#### CONSUMPTION IN MASSACHUSETTS.

We have obtained from Dr. George Derby advance sheets from the 26th Registration Report, which he is preparing for publication. We bespeak attention to the following extracts:

"Consumption caused the death of 4,362 persons in 1867; of which number 1,974 (45.2 per cent.) were males, and 2,388 (54.8 per cent.) were females. This number is 233 less than in 1866, and absolutely less than in any year of the past fifteen, with one exception.

The deaths by quarters of the year were as follows:—

First quarter,	1,129 or 25.88 per cent. of the whole.
Second "	1,102 or 25.26 " " "
Third "	1,083 or 24.83 " " "
Fourth "	1,048 or 24.03 " " "

Divided by seasons as follows:—

Spring,	1,179 or 27.03 per cent. of the whole.
Summer,	1,027 or 25.54 " " "
Autumn,	1,102 or 25.26 " " "
Winter,	1,054 or 24.17 " " "

Deaths from Consumption in the Counties, 1867.  
—Percentages.

[Dr. Derby's table is here omitted.]

Taking the last column as the measure of healthfulness with regard to this disease alone, the counties stand as follows: Franklin, Berkshire, Hampshire, Dukes and Nantucket, Barnstable, Norfolk, Hampden, Plymouth, Worcester, Bristol, Essex, Middlesex, Suffolk.

When the annual mortality from consumption in Massachusetts is regarded by itself, or compared with the deaths from all causes, or with the mortality from this cause in other countries, and in other parts of the United States, the impression left is liable to be an erroneous one. The figures are of a certain magnitude, and the conclusion may be hastily drawn that where a scourge prevails which causes nearly one death in every five of all ages, long life cannot be expected. We have seen that this is far from being the case, when considering our death-rate in comparison with that of other countries, in this and former reports. In point of fact the very largeness of the proportion of deaths from consumption to deaths from all causes, shows how great is our immunity from other fatal diseases. The malarial fevers which under various names are so destructive in our Southern and Western States, are almost completely unknown on our soil. Calculous diseases are exceedingly rare, affections of the liver infrequent. Our climate, although severe, does not induce that feeble condition of the body which renders it incapable of resisting the morbid influences by which all communities are surrounded. But even as regards diseases of the lungs in their various forms, we are not so afflicted as might at first appear, since, although consumption is a very common and fatal disease in Massachusetts, there are other affections of the lungs almost equally destructive of life in other countries from which we are singularly free.

*Number of Persons dying annually from Diseases of the Respiratory Organs (Consumption included) to each 100,000 living, in Massachusetts and in England.*

## MASSACHUSETTS.

	1863	1864	1865	1866
Consumption, . . . . .	372	376	368	361
Bronchitis, . . . . .	16	15	14	16
Pneumonia, . . . . .	137	143	118	128
Pleurisy, . . . . .	10	11	7	7
Laryngitis, . . . . .	1	1	1	1
Asthma, . . . . .	4	4	4	3

Totals, . . . . .	545	555	516	520

## ENGLAND.

	251	258	259	265
Consumption, . . . . .	157	189	175	197
Bronchitis, . . . . .	119	119	108	120
Pneumonia, . . . . .	4	5	4	4
Pleurisy, . . . . .	7	8	6	6
Laryngitis, . . . . .	18	20	19	17
Asthma, . . . . .	24	25	23	23
Diseases of the lungs not otherwise described, . .				
Totals, . . . . .	580	624	594	632

The preceding table presents evidence on this point drawn from the Registration Reports of Massachusetts and England for the four years ending with 1866.

The points of difference which seem most important to observe are, first and chiefly, the small mortality from bronchitis in Massachusetts as compared with England; the proportions are eight to ninety-two, or nearly one to twelve. This more than compensates for our greater mortality from consumption. The proportions for this disease are 58.8 in Massachusetts and 41.2 in England. From the two diseases combined there are 46.7 deaths in Massachusetts to 53.3 in England.

The mortality from pneumonia and pleurisy is seen to be a little greater in Massachusetts; but less from laryngitis, and from asthma. It is probable that the dyspnoea resulting from enlarged bronchi in chronic bronchitis is frequently called asthma.

Of diseases of the lungs not classified or particularly described, there are more in the English reports; but the aggregate of deaths from affections of the respiratory organs (including consumption), in a given number of the people of all ages, is greater in England than in Massachusetts.

*The liability to death from such cause is as 53.2 in England to 46.8 in Massachusetts.*

*Diminishing Mortality from Consumption in Massachusetts.*—The following table will make evident a fact to which reference was made in the Registration Report of 1865, and which well illustrates the value of vital statistics, since without their aid it could not be proved:—

*Mortality from Consumption in Massachusetts in each of the past fifteen Years.*

YEARS.	Population.	No. of Deaths from Consumption.	Deaths from Consumption to each 100,000 living.
1853, . . . . .	1,075,007	4,593	427
1854, . . . . .	1,103,351	4,611	418
1855, . . . . .	1,132,364	4,750	419
1856, . . . . .	1,151,455	4,701	408
1857, . . . . .	1,170,862	4,625	395
1858, . . . . .	1,190,592	4,574	384
1859, . . . . .	1,210,656	4,704	388
1860, . . . . .	1,231,066	4,557	370
1861, . . . . .	1,238,110	4,522	365
1862, . . . . .	1,245,310	4,269	343
1863, . . . . .	1,252,500	4,667	372
1864, . . . . .	1,259,710	4,733	376
1865, . . . . .	1,267,031	4,661	368
1866, . . . . .	1,274,310	4,600	361
1867, . . . . .	1,281,700	4,362	340

A comparison of the first two columns shows at a glance that the number of deaths does not increase with the population, and

in the third column, representing the mortality to a fixed number of the people, the constant improvement is plainly seen; not always from one year to the next, but perfectly evident when two or three years are taken together.

Comparing the first group of five years with the last group of five years, it is seen that the annual gain in each 100,000 of the population is 51 lives; this gives as the actual saving of life in the last five years 3,220 persons, or 644 in each year. From some cause, or combination of causes, deaths from consumption in Massachusetts have diminished by that amount, and the improvement seems to be still going on. It is of the utmost importance to discover what these causes are; but here statistics fail us, and we are left to conjecture. Our own belief is that they are to be found in the advance of medical science, which has given to physicians a better knowledge of the nature of the disease, derived from pathology; a better mode of treatment, derived from the careful observation of cases, and from modern discoveries in chemistry and physiology; and a greatly improved acquaintance with the means by which consumption may be avoided by those predisposed to it by inheritance, derived from all these sources combined.

This knowledge is becoming diffused among the people, so that all intelligent persons now know more about the prevention of consumption than the wisest physicians knew fifty years ago.

Fresh air by day and by night, strong and nourishing food, dry soil on which to live, sunlight, and warm clothing, are the means of saving many lives which would have been hopelessly lost in the preceding generation. If our conjectures are correct this improvement may be expected to continue, and everybody can help to make it greater. Ventilate the school-rooms, and the workshops, and the stores, and the houses; in cold weather let the air, comfortably and equally warmed, be generously supplied from without in a constantly flowing current. Let those who can provide it in their homes remember that an open fire, which sends two-thirds of the heat up the chimney, furnishes the best ventilation for a room of moderate size which the ingenuity of man has yet devised, and that the heat escaping by the flue is the price to be paid for it. Let in the sunlight, and never mind the carpets; better they should fade than the health of the family. When a man proposes to build a dwelling in a swamp, warn him of his danger.

HARVARD UNIVERSITY.—The following was the order of exercises at the Medical Commencement at the Massachusetts Medical College, Wednesday, March 10, 1869:—

Prayer, by Rev. Professor Andrew P. Peabody, D.D., LL.D. Dissertations selected for public reading:—1. *Hæmorrhage*. Frederick Lysander Burden, Scituate, R. I. 2. *Ergot of Rye*. Frank Winthrop Draper, Wayland, Mass. 3. *Digitalis Purpurea*. Francis Webster Goss, Salem, Mass. 4. *Cerebro-spinal Meningitis*. Charles Inglis Margeson, Wilmot, N. S. 5. *Hip Disease*. John Hildreth McCollom, Medford, Mass. 6. *Hypodermic Injections*. George Harlin Pillsbury, Lowell, Mass. Conferring of the Medical Degree, by Prof. Henry J. Bigelow, M.D., Dean. Conferring of the Degree of Dental Medicine, also by the Dean. Address by Prof. Edward H. Clarke, M.D. Benediction.

The dissertations were highly creditable to their authors.

The Address by Prof. Clarke was learned, far-reaching and suggestive. After saying that knowledge was increasing in a geometrical ratio, and that none but a seer or a fool would venture to cast the scientific horoscope of the next twenty years, he took the ground that the question of the present position of medicine offered itself under two aspects—1st, that of its relation to other sciences (this topic was waived as too vast for the occasion); 2d, of the relation of medicine, or rather of medical men, to the community—not as practitioners, but in more occult affinities. He then proceeded to discourse upon the attitude of our profession toward education in its broadest sense—inclusive of the school, the college, the press, and public opinion—toward law, and toward religion.

Female physic, if we may be allowed the term, was alluded to by Dr. Clarke. Throw no obstacles, he said, in the way of the experiment; but, he conjectured, it would be found that “a woman could not develop into a man, or a man into a woman.”

#### NOTES FROM THE UNION MEDICALE.

At the Académie des Sciences there has been a discussion on the nature of *solar light*, between MM. Faye, Chasles, Sainte-Claire Deville and Le Verrier. From the tenor of this discussion, it would appear

that the light of the sun is not attributable to the combustion of hydrogen; but that it proceeds from a mass of solid matter surrounded by hydrogen.

At the Mauritius, Dr. Jessier claims to have cured intermittent fever by phenic (carbolic) acid, in a patient with whom quinine had failed. Three fourths ( $\frac{3}{4}$ ) of a grain of the pure acid dissolved in twenty (20) drops of water were injected beneath the skin. MM. Barrant and Jessier consider that intermittent fever is due to the presence in the blood of a microscopical ferment—vegetable or animal.

#### BIRTH OF AN EXTRAORDINARILY LARGE CHILD.

—Dr. Brotherston, of Alloa, communicated to the Edinburgh Obstetrical Society, the following record of the birth of a gigantic fœtus:—I was called upon, Wednesday morning last, about half past five, to attend on Mrs. F., Alloa, who was in labor with her seventh child. Matters went on as usual till the head was expelled, and I expected that the next pain or so would terminate the delivery; but, on the contrary, though the pains were severe, and I applied a moderate degree of traction to the head, during nearly twenty minutes, I could not deliver the body of the child; the shoulders appeared to be the obstacle, and the right arm-pit could be reached by the finger without much difficulty. I sent for Dr. Duncanson, who came immediately, and he brought my instruments with him; we then applied the blunt hook to the right axilla, and, by traction of no ordinary kind, extracted a dead male child of the following dimensions:—Weight, 17 lbs.; length, 23½ inches; circumference round the head over the occipital and frontal prominences, 15 inches; circumference around shoulders, 20 inches; circumference around chest, 15½ inches; circumference around stomach, 17 inches; from funis to sole of foot, 10½ inches; from funis to head, 13 inches; circumference of thigh, 9 inches; length of leg from trochanter to heel, 10½ inches; length of arm, 10 inches. The measurements were taken in my presence by Dr. Duncanson and Mr. F., the father of the child. Mrs. F. is making a very favorable recovery. The father is six feet high—a very proportionate man, and rather good-looking, aged 44; weight 13 stone. The mother is 5 feet—rather stout, aged 40—was never weighed, but looks about 11½ stone. The child was perfectly formed in every way—no signs of hydrocephalus what-

ever. This will be seen by the measurement of the head, which was 15 inches and well formed. The child was living when the head was expelled from the pelvis and vulva, as it gave a convulsive effort, as if trying to pull back the head occasionally. This lasted about ten minutes. When these efforts went off, I believe the child died. I suppose the cause of death was pressure of the cord, the body of the child being of such a size as to effect this most readily. When the child was extracted, it was quite dead; its right humerus gave way near the neck, from the pressure of the blunt hook. There was no hemorrhage afterwards worth mentioning—just what is usual. Dr. Keiler thought this was about the heaviest child he had ever heard of. He had shown a fœtus some time ago, which had been delivered by craniotomy, and whose shoulders were so large that great difficulty had been caused in extraction. Even now, although preserved in spirit for such a length of time, this child still looked a giant, but he did not think it would weigh more than 14 lbs. He had heard of an American baby which weighed 19½ lbs. at birth. Dr. Pattison said there was a child in Dr. Thatcher's museum which weighed 16 lbs.—*Dublin Medical Press and Circular.*

In a case of labor we attended March 3d, 1869, we had a similar difficulty with the shoulders of the fœtus (weight 10½ pounds). We had used much force in delivering the head with the forceps; but with all the traction we dared to apply with both hands grasping it, we could not start the shoulders until we had engaged the index finger of the right hand in the left axilla of the fœtus. Then seizing the chin with the remaining fingers of the same hand, while the left hand was applied to the back part of the vertex, we with some difficulty extracted. The child was partially asphyxiated, but was resuscitated.

**VERTICAL DISLOCATION OF THE PATELLA.**—George M. Sternberg, M.D., Ass't Surg. and Brevet Major, U.S.A., in a letter to the *Philadelphia Medical and Surgical Reporter*, dated Camp Supply, Ind. Ter., Jan. 18th, 1869, says:—

“In the *Reporter* for December 19th is an account of a case of vertical dislocation of the patella, by Dr. Samuel Rittenhouse. I had a similar case about three months since. A colored cavalry soldier while riding his horse came in violent collision with another

mounted man. He dismounted, and finding that he was unable to walk, was carried by some comrades to his tent, and I was sent for. Upon examination I found his left leg extended and all motion of the knee-joint prevented by the patella, which was tilted upon its outer edge, the anterior surface looking outward. The patient was suffering severe pain in the joint.

"I immediately brought him under the influence of chloroform, and flexing the thigh upon the pelvis I grasped the patella in my right hand, and the ankle with my left. Then at the same moment I flexed the leg upon the thigh with my left hand and tilted the patella over to its place with the right.

"The reduction was accomplished very easily, the bone coming to its place with a loud snap. An hour after, the man was walking around without pain or inconvenience, and continued to perform all his military duties as usual."

**THE SIAMESE TWINS.**—A surgeon who would not hesitate to attempt the separation of two weakly and delicate children would hesitate to interfere with two aged men. In the case of Chang and Eng there is evidently a hollow proceeding for some distance along the band of union, and connected with either peritoneum. The question is whether the one cavity is continuous with the other, and, if so, what are their contents? We have given above good reasons for dreading the presence of a portion of either liver. This organ is so very plastic that it might easily enough be united in the two and yet give rise to no discomfort in the uniting band. That the one does not feel what is done to the other, is of no consequence; that the union is close between the two is clearly shown by their liability to simultaneous attack by constitutional maladies, as ague and measles. In the case of the former disease the periodicity was identical in both.

The prospect which now faces these unfortunates is no doubt a hideous one, but the immediate dissolution of both is more appalling, and we are thoroughly convinced that our Surgeons have acted wisely. Sound advice, and an almost womanish regard for human life, are the grand characteristics of English Surgery, and we are prouder of men who can dispassionately and skilfully consider the chances for and against the success of an operation, and finally decline to perform it, than we should be of one who, with a reckless disregard for consequences, would adopt a course which might end unfortunately both for the patient and himself.—*Lond. Med. T. & Gaz.*

**DEATH FROM CARBOLIC ACID.**—We lately noticed the report of a death from the injection of carbolic acid into the bowel which occurred in the Worcester Infirmary. It seems, from a correspondence which has lately been published in the *Times*, that the mistake arose from the use of the word "injection." The Surgeon, Mr. Budd, directed the use of a solution of carbolic acid, which was to be injected, a tea-spoonful at a time, with a glass syringe in the case of a patient suffering from urinary fistula. The dispenser mislaid the direction, and sent the solution to another patient, who was also in the Hospital with urinary fistula, to whom the nurse administered it as an enema. The man died within a few minutes. Mr. Budd promises the publication of an accurate account of all the circumstances of the case after it has been investigated at a special meeting of the governors of the Hospital.—*Ibid.*

**TREATMENT OF EPILEPSY.**—Dr. H. Beigel, speaking of epilepsy, says:—

Concerning treatment, we are all aware that amongst the large number of remedies, such only have any visible effect as belong to the class of nervines. According to my experience, which extends over several hundred cases, there are only two remedies which render good, and even very good service, in the treatment of epilepsy—namely, large doses of bromide of potassium and morphia if used hypodermically. I have tried nearly all drugs recommended by the authors on epilepsy, but failed to see any result worthy of notice. But bromide of potassium has doubtless the power of delaying the attacks, so that a patient who has previously had perhaps several fits in one week, has one every few months—a delay which remains stationary in many cases, even after the remedy has been left off, provided it has been taken for a sufficiently long period. The same result is obtained by hypodermic injection of morphia, which acts much more rapidly and intensely. I use the bromide of potassium in children and in such adults as are ill-nourished, and employ hypodermic injections if no other complication exists with true idiopathic epilepsy.—*Ibid.*

At a meeting of the Medical Society of London, Jan. 4, 1869, a communication was read from Dr. B. Foster on Etherized Cod-liver Oil—that is, the addition of 10, 15, or 20 minims of pure ether to every 2 drachms of the oil, which he has found less nauseous, and more easily digested than the oil alone.

## Medical Miscellany.

At the meeting of the Boylston Medical Society, held Friday, Feb. 19th, a first prize was awarded to Mr. F. W. Draper for an essay on the Physical and Therapeutical Relations of Ergot of Rye, and a second prize to Mr. J. J. Putnam for an essay on the Physical Principles which govern the application of Counter-irritants.

THE Dental Faculty of Harvard University entertained and were entertained at Prof. Keep's on Wednesday evening of last week. In the course of the evening there was a lively discussion of the process of filling. At the same time, our types had just ranged themselves under the magic spell of "the Professor" to show how well the dentists have developed their wisdom teeth.

DURING the term of service, March, April and May, the undersigned will be happy to have practitioners and third-year students visit the Massachusetts Charitable Eye and Ear Infirmary any day from 9 to 11, A.M. Operations generally take place at 9½ to 10, A.M.

HASKET DERBY,  
F. P. SPRAGUE,  
B. JOY JEFFRIES,  
ROBERT WILLARD.

**CORRECTION.**—In the list of graduates of the Massachusetts Medical College, printed in our last issue, is the name of Dr. Erastus Emery. His residence should be given, we are requested to say, as Chatham, Mass., instead of Binghamton, N. Y.

We do not vouch for the following item, which has been sent us. A surgeon in a distant place is said to have removed a tumor weighing 63 lbs., and thinks of presenting it to General Grant.

**A PROFESSIONAL CONUNDRUM.**—Why is a convalescent like the U. S. Treasury Department? Because he has got about well!

**ON LUMBAR COLOMOTY.** By C. F. MAUNDER, F.R.C.S.—There are several diseases or states of bowel in which this operation is practised.

1. For irremediable obstruction in order to prevent speedy death.

2. For obstinate stricture, malignant or benign, situated either high up or low down in the rectum, for which relief to distressing and exhausting symptoms cannot be obtained, after a judicious trial, by more simple measures.

3. For painful cancer of the rectum (non-obstructive), in which the patient's life is rendered miserable, and would soon be closed by exhaustion—consequent partly on excruciating pain caused by the passage of feces over the diseased and exquisitely sensitive bowel, and depriving him both of appetite and of sleep; and partly on profuse discharges, purulent, sloughy, and sometimes dangerously hemorrhagic. In this instance, the disease, though incurable, progresses more slowly when the morbid structures are no longer irritated, and a vast amount of pain is prevented.

4. For irremovable tumor of the rectum.—*London Med. Times and Gazette.*

**DEATH IN THE VAT.**—A sad accident, causing the deaths of two men, at Trowbridge, during the past week, by suffocation from carbonic acid in a beer vat, reminds us of having, some years ago, seen a suggestion made in a Calcutta newspaper that there should be attached to all such vats a light elastic tube, with wire coiled on the inside to prevent constriction, and a mask, with a valve to permit the escape of expired air, to be applied, in all cases, over the face of a person descending for the purpose of cleaning out the vat. Had such an apparatus been in use in the instance under notice, two lives would have been saved. When a vat contains refuse hops and grains above the level of the outflow tap, it is, of course, impossible for poisonous gases to escape through that channel, so that opening the tap for some hours will not necessarily evacuate the gaseous contents, and, time being valuable in these go-ahead days, it seems to us that it would be extremely desirable that a simple apparatus, such as that above described, should be introduced for trial at least in some of our large breweries.—*Ibid.*

## MEDICAL DIARY OF THE WEEK.

MONDAY, 9, A.M., Massachusetts General Hospital, Medical Clinic. 9, A.M., City Hospital, Ophthalmic Clinic.

TUESDAY, 9, A.M., City Hospital, Medical Clinic; 10, A.M., Surgical Lecture. 9 to 11, A.M., Boston Dispensary. 10-11, A.M., Massachusetts Eye and Ear Infirmary.

WEDNESDAY, 10, A.M., Massachusetts General Hospital, Surgical Visit. 11 A.M., OPERATIONS.

THURSDAY, 9 A.M., Massachusetts General Hospital, Medical Clinic. 10, A.M., Surgical Lecture.

FRIDAY, 9, A.M., City Hospital, Ophthalmic Clinic; 10, A.M., Surgical Visit; 11, A.M., OPERATIONS. 9 to 11, A.M., Boston Dispensary.

SATURDAY, 10, A.M., Massachusetts General Hospital, Surgical Visit; 11, A.M., OPERATIONS.

**TO CORRESPONDENTS.**—The following communication has been received:—Galvanism as an Antidote for Poisoning by Gelsemium Sempervirens.  
Dr. O'G.'s remittance received from abroad.

**PAMPHLETS RECEIVED.**—The Life of the Trichina, By Rudolph Virchow, M.D., Ph.D., Prof. University of Berlin. Translated by Rufus King Brown.—Fifty-fifth Annual Report of the Trustees of the Massachusetts General Hospital, 1868.—Addresses delivered at the Twentieth Annual Commencement of the Medical Department of Georgetown College, D. C., with a Catalogue of the Faculty and Students.

**DEATHS IN BOSTON** for the week ending Saturday noon, March 13th, 107. Males, 54—Females, 53.—Accident, 3—aneurism, 1—apoplexy, 1—disease of the brain, 2—inflammation of the brain, 2—bronchitis, 1—burns, 1—cancer, 1—canker, 2—cholera infantum, 1—consumption, 18—convulsions, 7—croup, 3—cyanosis, 1—debility, 1—dropsy of the brain, 1—erysipelas, 2—scarlet fever, 10—typhoid fever, 1—hemorrhage, 1—disease of the heart, 4—infantile disease, 4—insanity, 2—disease of the kidneys, 4—congestion of the lungs, 2—inflammation of the lungs, 9—marasmus, 1—old age, 1—paralysis, 1—peritonitis, 1—premature birth, 3—puerperal disease, 1—scrofula, 1—teething, 1—tumor, 1—unknown, 10—whooping cough, 1.

Under 5 years of age, 51—between 5 and 20 years, 8—between 20 and 40 years, 17—between 40 and 60 years, 16—above 60 years, 15. Born in the United States, 76—Ireland, 23—other places, 8.

### HAY FEVER OR ROSE COLD.

Clinical Lectures upon Spasmodic Coryza, or Periodical Asthma, with Naso-bronchial Congestion, delivered at the Hôtel-Dieu by Prof. Noël Gueneau de Mussy.

Translated for the Journal from the Gazette des Hôpitaux, by W. F. MERRILL, M.D.

B—, aged 42 years, born in Holland. The only pathological family history which can be elicited is that his mother was subject to sore throats. Health perfect during childhood. In 1845, when in the army, he was taken, after exposure, with fever and a pain in the side, which confined him to the hospital thirty-six days. He affirms that he uses spirit to excess but rarely, his daily allowance consisting of a litre of light wine and two glasses of brandy.

For the last nine years he has occupied a dark and damp lodging in Paris; nevertheless his general health has been good with the exception of occasional gastric pains and sore throats, which have occurred at two different periods, and have resulted in abscesses of the tonsil. He is also very subject to coryza during the winter. In 1845, he was affected for the first time, *during the winter*, with a serous discharge from the nose, accompanied by sneezing, itching and watering of the eyes. At the end of a month these symptoms disappeared. The following winter, for the first time, he experienced a well characterized attack of spasmodic coryza, which lasted about a month, and recurred in the succeeding year, in June, following an attack of tonsillitis, with the symptoms which we find to-day with the third attack.

The trouble has commenced this year at the same epoch as that of last year, i.e., in the early part of June.

The patient felt, in the first place, a sensation of painful fulness and weight in the head; his eyes watered; soon he began to sneeze and his nose to discharge; then the throat became painful. Later the pain spread to the left ear, accompanied by an uncomfortable blowing sensation. The patient

coughed a little, suffered from dyspnoea, and was prevented from sleeping by headache and the respiratory troubles. He is now dejected, exhausted and pale, and has a puffy look about the eyes. Upon the face and the back are quite numerous cicatrices and pustules of acne. There are patches of pityriasis upon the chest, and of intertrigo in the genito-crural fold. By everting the lower lids we find them much injected, velvety, and covered by fine granulations; the pharynx is red and very vascular, and numerous red granulations can be detected through the layer of transparent mucus which covers it like a varnish. Others can be seen upon the pillars. On the left posterior pillar is one yellow at the centre, and resembling a pustule of acne. The uvula is large, red, swollen, lengthened and twisted at its lower extremity, which sweeps the base of the tongue, behind which it conceals itself. The posterior part of the roof of the mouth is sown with small, whitish, semi-transparent granulations, resembling insects' eggs, the ordinary appearance of granulations in that region. Over the chest, including even the præcordial region, the sonority is slightly exaggerated, while the respiratory sounds are feeble, especially at the bases. In front, the expiration is sibilant. There is slight emphysema. The arteries are a little hard, sinuous, and at the apex of the heart a slight prolongation is noticed.

The patient complains of an habitual state of discomfort, consisting of a general malaise, headache, ear-ache, and a sensation of tightness in the nose, throat, and chest. In addition to this he is subject to paroxysms, occurring several times a day, the first usually in the morning about four hours after rising, and the others at intervals of about two hours. Ordinarily they grow feebler and disappear by evening. Sometimes, however, they recur during the night, and are accompanied by such difficulty in respiration as to force the patient to sit up. The phenomena accompanying these paroxysms succeed one another in the following order:—

They commence by the appearance or aggravation of the headache, the principal

[WHOLE No. 2143.]

location of which is in the frontal and occipital regions. At the same time there is a sensation of weight in the head; soon he has a pricking feeling in the nose, repeated sneezing, and an abundant secretion of viscous serum from the nostrils; the eyes itch and water. To these symptoms must be added a slight cough, followed by a frothy, viscous expectoration, mixed with small pearly masses. The painful sense of constriction in the throat often appears to the patient the cause of the dyspnoea.

After four days of unsuccessful expectant treatment gr. x. of sulphate of quinine were prescribed, and the pharynx and uvula touched with a solution of perchloride of iron. An immediate amelioration was the result. The paroxysms diminished in frequency and severity, and the nasal secretion became much less abundant. The patient slept, recovered his spirits, and thinking him on the way to recovery, I discontinued the local application; but three days later, the weather having become considerably colder, the coryza returned as severe as ever. The uvula and pharynx, which had been somewhat modified by the astringent applications, were as congested as on the first day. Should the suspension of the local treatment or the moist coolness of the weather be blamed for this relapse? I am now going to employ local treatment alone for several days, and if the result is not satisfactory, shall excise the uvula, which must be one of the principal causes of the oppression and constriction in the throat.

These complications and the rôle which I attribute to them do not affect my diagnosis of spasmodic asthma. In several of the cases which I have seen the granular condition has existed; it may act as a predisposing cause of the coryza, as it has appeared to me to act in the laryngismus stridulus of children. A more exceptional fact is the occurrence of the two first attacks in winter; but if, as I believe, the emanations from hay and other causes assigned for the disease intervene only as exciting causes, it can be understood that certain idiosyncrasies or circumstances in the life of the patient may modify the influence of the season.

Certainly, in four consecutive years this man has had a coryza, lasting longer than ordinary coryzas, preventing him from work and sleep, and accompanied by dyspnoea and nervous symptoms, with irregularly periodical exacerbations.

Twice in succession this affection ap-

peared in June; the two preceding years it appeared in the winter. If it be not the disease in its most marked and classic form, still I think that no other name can be applied to it. There is no law without exceptions for the periodicity of diseases.

This patient presents a form of the disease which I shall call spasmodic coryza, periodical asthma, or naso-bronchial congestion, which has also been designated as hay asthma, hay fever, summer asthma, or catarrhal summer asthma. My house physician and friend, M. Allan Herbert, has called my attention to an interesting article upon the subject by Elliotson, which eminent pathologist considers the affection as a mixture of asthma and catarrh. These are in reality the two essential elements of the disease.

Following the localization of the morbid action, we recognize two forms which may succeed or combine with each other.

The first is a coryza which generally returns in the late spring or early summer, lasting five or six weeks, sometimes even two or three months, with an obstinacy, an abundant discharge from the nose, and a sneezing which render it a veritable infirmity.

Sometimes the commencement is marked by febrile symptoms, after which the coryza sets in with paroxysms, at times periodical, at times brought on by outside causes, such as the heat or the weight of the atmosphere, the emanations from hay or exposure to the rays of the sun.

During these paroxysms the eyes, which become red and watery, are the seat of an insupportable pricking and itching, to which the rubbing and scratching, from which the patients cannot restrain themselves, give momentary relief; the lids are red and cedematous. These morbid sensations spread to the nasal fossæ, and then commences an almost continuous sneezing, an abundant serous discharge from the nostrils; the head becomes painful from the congestion of the nasal cavities and the violence of the shocks. The pain, most severe in the frontal region, sometimes extends to the occipital region, and may persist in the intervals of the paroxysms with severity enough to trouble the sleep.

Often, among the phenomena of the coryza, the spasmodic element shows itself, as in our patient, by a slight dyspnoea which may contribute to the insomnia. This is preceded by a sense of heat, pricking and tickling in the throat. At times the congestion may extend to the ears by the Eus-

tachian tubes, as in this case, in which the patient complains of disagreeable sensations and a blowing sound in the left ear.

The coryza may be the second part of the disease, being preceded several days by a catarrhal conjunctivitis with redness, swelling, and an insupportable tickling and itching. The action of the lachrymal and meibomian glands is exaggerated, and each sneeze causes, as it were, a spurt of the liquid which they secrete. In some cases we find an abnormal development of the carunculæ of the lids, necessitating removal.

Dr. Bostock, in Vol. viii. *Med. Chirurg. Transactions*, gives a very interesting example in his own case of this conjunctival catarrh which occasionally precedes the coryza.

This physician, who was forty-eight years of age when he wrote the account of his case, had been subject to the disease for forty years. At the beginning or the middle of June each year, he experienced in the eyes a sensation of heat and fulness, more pronounced along the ciliary edges, and especially toward the internal angles. In the beginning the only objective phenomenon was a slight injection and watering. This condition gradually increased, until he experienced an insupportable itching and pricking, as though small points were being driven into or pressed against the globe of the eye. There was an abundant secretion of thick mucus by the inflamed conjunctivæ.

These morbid phenomena continued in paroxysms from the second week in June until the middle of July, during which time the eyes were very rarely in a normal condition. The more violent paroxysms, however, occurred two or three times a day, and were generally provoked by some outside cause, such as the heat of the sun's rays, dust, or heat with dampness. After a longer or shorter duration the inflammation and hyper-secretion of mucus gradually decreased, but, even in the intervals, the sense of constriction and stiffness in the eyes continued.

Eight or ten days after the first appearance of the trouble the patient complained of a heavy feeling in the head, more marked in the frontal region. To these symptoms succeeded violent crises of sneezing, which recurred at irregular intervals.

Eight years later, when about 16 years old, Dr. Bostock began to experience, after these symptoms, a sense of tension in chest, and dyspnoea, accompanied by irritation of the throat and trachea. The chest was not exactly painful, but seemed to refuse en-

trance to the air. The voice was hoarse, and prolonged conversation could not be indulged in. Limited in its earlier phases to the eyes and nostrils, the morbid process had extended in a slight degree to the respiratory organs.

When the phenomena above indicated had lasted for some time, the patient began to suffer from a general malaise, muscular weakness, exhaustion, anorexia, insomnia, night sweats, and a loss of flesh. The pulse rose from 80, its ordinary frequency, to 100 and even to 120. All these symptoms disappeared toward the end of July, but the weakness and languor persisted for a month or six weeks. Fresh air and repose at times, prevented the return of the paroxysms.

The disease may appear in a less marked but not less obstinate form, in which the catarrhal element is more conspicuous than the nervous. In this form we find the nasal flux and obstruction which, at times, interfere with respiration, and less frequent and also less convulsive sneezing. I have observed this form in middle-aged people who have appeared to me under the mixed influence of the arthritic and lymphatic temperament, with predominance of the latter.

As a type of the form in which the coryza predominates, I will cite the case of a lawyer, belonging to a gouty family, whose father and mother had both suffered from hepatic colics. He himself has been tormented with nervous troubles ever since his early youth; at times by an extremely violent and obstinate facial neuralgia, commencing on the right side, and extending to the left, and accompanied by a twitching, which continued during several years, even in the interval of the neuralgic attacks. At other times the lumbo-abdominal, or the sciatic and crural nerves have been the seat of pain; when the latter, there have been twitching in the feet, cramps and cutaneous anæsthesia of several toes. In one attack of the lumbo-abdominal neuralgia, a transient paralysis of the bladder supervened, and had to be treated by electricity. These attacks, some of which lasted eight or ten months, resisted the whole arsenal of therapeutics, and yielded only to sulphureous mineral waters. The patient presented the additional peculiarity which I have remarked in some other cases, i. e., an eczematous eruption of several weeks' duration was produced by the local application of opiates. Alcohol and camphorated alcohol were perfectly well supported.

I have dwelt at length upon the constitutional condition in order to show in what

diabetic conditions the spasmodic coryza was developed. Before, as well as since the appearance of these nervous affections, the patient is attacked every spring, when he goes to the country, by a coryza, lasting five or six weeks, and tormenting him by its violence and the abundance of the nasolachrymal discharge by which it is accompanied.

I have lately seen two sisters belonging to an arthritic family, the elder of whom, aged about 35, consulted me a year ago for a chronic urticaria of five or six years' standing. This I treated very successfully by small doses of arsenic and alkaline baths very slightly impregnated with sulphur. She returned to me this time on account of a coryza which commenced about the first of May, and gave her the more anxiety inasmuch as her mother had suffered during the past thirty years from the same affection. In the mother's case, this returns regularly in May and continues until the last of August. Her grandfather is exempt, but his brother and his brother's son are both subject to the same disease. There is a history of gout in the family, and the patient herself is subject to sick head-aches, and has loaded urine. Her pharynx is studded with large bright red granulations, which extend even into the posterior nasal fossæ.

[To be continued.]

### CLINIQUE IN AURAL SURGERY

Of Dr. ADAM POLITZER, University Lecturer in the General Hospital, Vienna.

Observed and reported by C. J. BLAKE, M.D.

THE following cases are worthy of notice, the first from the fact of the patient's retaining an almost normal degree of hearing notwithstanding the existence of a serious lesion, and the second from the success of a new method of treatment, employed to preserve the artificial perforation of the tympanum.

I.—Woman, æt. 20, a patient with tuberculosis, in Oppolzer's ward, Vienna General Hospital. The aural examination was made in this case, not from any symptoms of disease of the ear, but in accordance with the general custom in this clinique. With both ears, the watch was heard at a distance of one foot, and the voice, in a whisper, the length of the ward (about 90 feet). Examination of the tympana showed in each a perforation about  $2\frac{1}{2}$ " in length, and situated behind the manubrium mallei; the remainder of the tympanum, with the exception

of a small rim at the periphery, was infiltrated with calcareous deposit. When a child, the patient had severe pain in both ears, followed by a discharge, but no deafness.

Death occurred a few days after this examination, and an autopsy confirmed the observations above described. In the fresh state, the calcareous mass was so firm as to be immovable under a strong pressure, and the deposit had not only impregnated all the layers of the tympanum, but extended above the surface of the mucous membrane into the tympanic cavity, and the malleus was so firmly embedded that no vibration could have been transmitted by it to the other ossicles. The patient was able to bear, and had heard since childhood, inasmuch as the perforation permitted vibrations to pass into the tympanic cavity, and fall directly on the stapes, which was freely movable. The labyrinth was perfectly normal. Had the opening been closed by cicatricial tissue, it would have been necessary to make an artificial perforation in order to permit the passage of vibrations and to give to the patient the degree of hearing, which, as the case stood, she did possess up to the time of her death. The importance of retaining or reproducing a perforation of the tympanum in some, and by no means infrequent diseases of the ear, is illustrated by this as well as by the following case.

II.—On the 22d of October, 1868, Anna P., æt. 48, a native of Vienna, first presented herself at Politzer's clinique. Two years before, according to her account, she was suddenly seized with severe pain in the left ear; the pain lasted for eight days, and was followed by a copious secretion. This also ceased in a few days, but deafness, and the passage of air through the meatus on blowing the nose, continued for some weeks. An application to the meatus, ordered by a physician, did much to diminish the secretion and decidedly improved the hearing; this improvement lasted but about two months, and at the end of that time she began to experience troublesome sensations in the ear, such as loud ringing and rushing sounds.

A marked degree of deafness was observed at the date of admission; this had lasted for a year.

The trouble in the right ear dated from three months before admission; it commenced in the same manner as in the left ear; the pain continued, notwithstanding the appearance of a purulent secretion on the first day, for a period of three weeks.

The secretion and the sensation of a hissing sound in the ear were still present upon admission.

On examination, the left tympanum appeared of a dull-grey color, the short process of the malleus and the folds running outward from it were very sharply marked, and the manubrium mallei drawn inwards and less clearly defined than usual; below the manubrium was a dark and depressed spot of an oval form and about 1" long by  $\frac{3}{4}$ " wide, which was recognized as the cicatrix of a previously existing perforation. The ticking of a watch could be heard only when the watch was brought in contact with the ear, or when it was pressed upon the side of the head; and the voice at no greater distance than 3'. After the injection of air into the Eustachian tube by Politzer's method, the cicatrix was seen to have been forced outwards, and the distance at which the voice was heard was increased by one foot, but it was still necessary to bring the watch in contact with the ear. In the right tympanum, situated below and anteriorly to the manubrium mallei, was a circular perforation of the size of a pin's head, through which a drop of thick pus and a few air-bubbles were forced by the employment of Valsalva's method. After removal of the pus, the watch was heard at a distance of 2", and when pressed upon the head in front of the ear, the voice at a distance of 5 feet. The tuning-fork, placed over the sagittal suture, was most clearly heard in the left ear, because the obstructions to the passage of vibrations from without retained those which were communicated to the tympanic cavity through the medium of the bones of the head. The results of the examination showed the existence of purulent catarrh of the tympanic cavity of the right ear, with perforation of the tympanum. The same process had existed in the left ear, but the purulent secretion from the mucous membrane of the tympanic cavity had ceased more than a year previously, and the perforation in the tympanum had been closed by cicatricial tissue. The fact that a decided improvement in hearing followed the injection of air, favored the supposition that the deafness resulted neither from closure of the Eustachian tube nor from a collection of mucus in the tympanic cavity, but from (old) adhesions between the ossicles and the tympanic walls.

The previous history showed that as long as the patient was able to force air outwards through the meatus, that is to say, as long as the perforation existed, the loss

of hearing on this side was but slight, whereas the closure of the opening was followed by decided deafness. These facts justified the conclusion that either the malleus or incus was attached to the wall of the tympanic cavity by firm bands of connective tissue. So long as the perforation in the tympanum existed, the vibrations could pass through it, and, striking upon the base of the stapes, be communicated to the labyrinth. After the closure of the opening, the vibrations impinging upon the tympanum were no longer communicated to the stapes, because of the resistance of the malleus and incus. The indication for treatment in this case was the removal of the thin cicatrix in the tympanum, in order that vibrations might be admitted to the tympanic cavity through the perforation.

The excision of a portion of the tympanum in certain cases of disease of the ear, was first recommended by Riolan in the 17th century, but from the doubtful results of the operation very little regard was paid to it by the more celebrated surgeons of the time. The first and most important scientific communications concerning the artificial perforation of the tympanum, date from the beginning of the present century; when Astley Cooper and Himly, simultaneously and independently of each other, re-introduced, and, encouraged by the favorable results at first obtained, strongly recommended it. They became convinced, after long trial, of the difficulty of making the artificial opening a permanent one, and finally abandoned the attempt; but in the meantime their favorable reports having reached the continent, the operation was performed in both France and Germany on hundreds of cases, in almost every one of which, however, the first gain proved to be but temporary, for, sooner or later, the opening became closed by cicatricial tissue.\* Pieces of catgut cord, splinters of whalebone, &c., were introduced, and the edges of the perforation touched with caustics, but without favorable result. Bonnafont† in one case introduced a silver canula and allowed it to remain forty-five days, but the closure of the perforation followed its removal. Many instruments have been devised for the purpose of removing a portion of the tympanum. Among the latest are those of Wilde, Toynbee and Gruber, but none of them has succeeded in gaining a

\* Schwartz. Studien und Beobachtungen über die Künstl. Perforation des Trommelfells. Archiv für Ohrenheilkunde. 2 Bd.

† Traité théorique et pratique des Maladies de l'oreille. Paris. 1860.

decidedly favorable result. The operation proposed by Menière, of perforating the tympanum by means of caustics, seems to have been equally unsuccessful, and concerning Sphierotomie we have as yet no definite reports of success. The indications for the operation in the present case induced Dr. Politzer to make the attempt of establishing a permanent artificial perforation by means of a new method, and on Oct. 26th he operated, as follows: A large sized aural speculum having been introduced, and the tympanum illuminated by means of a reflector, an incision was made with a paracentesis knife, through the cicatrix parallel to its long diameter, and a "laminaria-stübchen"\* introduced and allowed to remain for two or three hours, by which time it had sufficiently expanded. Its removal showed a circular opening in the tympanum, through which a hard rubber eyelet (öse), having several rims, was pushed into the tympanic cavity to the depth of  $\frac{1}{2}$ ". The pain resulting from the operation was very slight. Through the opening of the eyelet the mucous membrane covering the promontorium, of a light reddish yellow color, could be plainly seen, and the patient voluntarily declared, not only that she heard better, but that the sensation of noises in the ear had very much diminished. It having been ascertained that the eyelet was firmly fixed, the edges of the perforation having slipped into one of the grooves between the rims, the hearing power was carefully tested. The watch which it had been necessary before the operation to bring in contact with the ear, was now heard at a distance of 9", and the voice at a distance of 40 feet instead of 3 feet.

On the 10th of February I had opportunity of examining the case above described. The eyelet, which is about the diameter of a common steel knitting-needle, projects two lines or more from the tympanum and rests upon the posterior inferior wall of the meatus; it is closely encircled and firmly held in place by the edges of the perforation. The patient does not notice its presence in the least, and is entirely relieved from the previous unpleasant sensations in the ear. The ticking of a watch is heard at the distance of 14", and words spoken in the ordinary tone of voice throughout the length of Oppolzer's ward, a distance of about 90 feet.

The right ear having been treated with intonation, Politzer's method, and the appli-

cation of pulv. aluminis, the purulent exudation ceased, and the perforation became closed by cicatricial tissue about four weeks since. On examination the cicatrix, 2" in diameter, is readily seen, and the hearing power is normal. In this ear the disease having been treated in season, the ossicles retain their normal relations to each other and to the walls of the tympanic cavity.

FIG. 1.

FIG. 2.

The eyelets (made by Leiter of Vienna) are of hard rubber and from 1" to 1 $\frac{1}{2}$ " in length; the longitudinal opening is oval in form and about  $\frac{1}{2}$ " in its longest diameter. On the outer surface are either one (Fig. 1), or two (Fig. 2) grooves. In the outer end is a small transverse opening for the passage of a silk thread, by which the eyelet can be withdrawn in case of its slipping from the pincette during the operation.

The pincette used in introducing the eyelet terminates in two sharp points, which being inserted in the longitudinal opening and then expanded, give a much firmer hold than if the eyelet were grasped from the outside.

#### SINGULAR OBSTETRICAL CASE.

By THOMAS W. PERRY, M.D., Providence, R. I.

THE following case occurred in my practice, Sunday, Dec. 13, 1868. At 1, P.M., was called to an Irish woman in labor with her first child. Moderate pains commenced soon after midnight, but became severe by 7 or 8, A.M. These continued increasing in severity until the termination of the labor. The child was born as I entered the room. I separated the cord, and gave the child into the hands of an attendant. There was a laceration of the scalp, extending from near the top of the right ear across the parietal bone and suture to the opposite parietal bone, making a wound four inches in length; there was a fracture of the right parietal bone in a straight line across, one inch in length; the bone was denuded of its periosteum to the extent of about one half the size of a silver half dollar—the whole making a frightful-looking wound. There was also a laceration of the perineum of the mother, extending down to and back of anus, not rupturing the sphincter ani, but going around and back of the anus, like the half of the letter S. I brought the parts in apposition with four lead sutures, put in deep, tied the knees together, and got a good union.

\* Laminaria, a species of Alga, possessing the expansive properties of pressed sponge, and employed for the same purpose.

Regarding this as a case of great interest, I called Dr. Caswell, who kindly assisted in dressing the wounds. Both mother and child are doing well. The patient was attended by an old woman with whom I have been well acquainted for years, and who is, in my opinion, incapable of malice. She was also surrounded by half a dozen other women, among them the mother of the patient; apparently, there was no possible way for the child to have received this wound from any of the attendants. Neither Dr. Caswell nor myself could discover any spicula of bone from the bones of the pelvis. Suppose this child had been dead born and no person present except the mother, and this wound had been on the head of the child, the question would be, who or what killed the child.

A few nights since, I was called to attend a servant-girl, alone in an attic, and the child was stillborn. Suppose the wound had existed on this child's head; what ought to have been my testimony? Could such a wound be produced by natural process of labor? I have been in the practice of medicine twenty-four years, and during the past twelve years have seen a great deal of midwifery, but have never seen a case resembling this; neither has my partner, Dr. Capron.

March 1, 1869.—I examined the child's head this day. The wound healed by granulation. Several small pieces of bone have exfoliated, leaving a portion of the brain, about the size of a silver half dollar, unprotected by bony covering.

The laceration of the perinæum healed satisfactorily.

of his profession, his diligence in the pursuit of knowledge, his strict attention to duty, and his straightforward and truthful character, gave promise of an honorable and successful career in the practice of medicine, and endeared him to his brother practitioners with whom he was brought in contact.

*Resolved*, That the community have lost a man who had already attained an enviable position in the hearts of his fellow-men, and who by his activity in every good work, his intelligent and generous course in all the movements of the day—political, benevolent, educational and religious—gave assurance of a large influence for good, and of conferring lasting benefits upon the community in which he lived.

*Resolved*, That these resolutions be placed upon the records of this Society, and that a copy be sent with the proceedings of this meeting for publication in the Boston Medical and Surgical Journal; and also that the Secretary furnish a copy to the friends of the deceased.

*A Case of Pericarditis; Abscess between the Heart and Pericardium in a Child.* Dr. Morris Spofford reported the case.

C. B. was a very bright, active boy of two years and three months; so active that he kept the household and the neighborhood in terror lest he should kill or drown himself.

I was called to see him, Dec. 8th. Insensible; in convulsions; eyes rolled up, fixed. Had been thus an hour. Had vomited some hours before, and had thrown up, among other ingesta, some large, unmasterated pieces of fat pork.

I administered submur. hyd. gr. v., with ol. tigllii gtt. i. In half an hour he was sensible, and the next morning was much as usual.

He had a slight return of the convulsions the second day after, which passed off with the application of mustard poultices to his feet and a warm bath.

For a week after, he presented most of the symptoms of remittent fever; being comfortable in the morning, feverish and distressed in the afternoon and evening, showing signs of uneasiness about the head, with a teasing cough and a pulse of about 140.

Suspecting that worms might be at the bottom of the disturbance, I gave him ol. chenopodii gtt. xii. in divided doses, and was gratified next day to see eight large lumbrici as the result. To my disappointment, their evacuation produced no amendment, and after three days the dose was

## Reports of Medical Societies.

ESSEX NORTH DISTRICT MEDICAL SOCIETY.  
G. W. GARLAND, M.D., SECRETARY.

The meeting was held at the house of Dr. Whittemore, of Haverhill, who furnished a sumptuous entertainment.

The following preamble and resolutions were passed:—

Whereas an All-wise Providence has removed from us, by death, Dr. Albert Field Scruton, the following resolutions are adopted by this Society.

*Resolved*, That by the death of Dr. Scruton, almost at the commencement of his professional career, this Society and the medical profession have lost a member who by his thorough preparation for the duties

repeated, but no more worms were discharged.

For a fortnight longer the pulse kept at 140 to 170. The cough became more distressing, the countenance anxious, the eyes wild, with twitchings resembling those of eclampsia about the face (though he retained his senses most of the time to the last, putting out his tongue for m inspection as soon as I entered the room). A large abscess collected just below the patella; the left arm became paralyzed and remained so until his death, which occurred twenty-eight days from the first attack.

Dr. Root very kindly gave me his assistance at the autopsy.

The lungs were generally pale, collapsed, occupying less than half the cavity of the thorax. There was slight pleuritic adhesion in the scapular region of the left side, and to the diaphragm on the right. The right lung was curiously marked with engorged patches in front, extending to the depth of half to three quarters of an inch, out of which issued, on pressure, bloody serum mixed with pus. The cavity of the thorax contained half a pint of bloody serum.

The pericardium was adherent to the heart through its whole extent. At the lower third it could be peeled off with the fingers, as you would peel an orange, leaving a rough, tripe-like surface. In the upper portion the scalpel was required; and, in dissection, an abscess was revealed, enclosing about a fluidrachm of laudable pus. The interior of the heart appeared perfectly healthy, though the whole organ seemed to me somewhat hypertrophied.

Having thus found abundant cause of death, we made no examination of the other organs.

The heart sounds, so far as my ear could distinguish, had been natural throughout, though he was so impatient of the slightest pressure about the thorax that auscultation was not quite satisfactory.

*Retained Placenta.*—Dr. O. S. Lovejoy reported the case.

June 12th, 1864.—Was called to see Mrs. W. Found her in bed, and was informed she had the day previous been delivered (after a six months' pregnancy) of a dead fetus. On inquiry, found the child had not been disposed of, and on examination and from the mother's statements concluded the time was nearly correct. The child had evidently been dead several days, as portions of it had sloughed away. There were no traces of any cord, and the womb had contracted so firmly as to prevent the

entrance of more than two fingers. I could distinctly feel the edge of the placenta within the womb.

I advised with one or two of my professional brethren, and with their opinion came to the conclusion that it would come away if left to itself. The patient recovered health and strength, and in a few days was about her household duties as usual. I was called to see her about once in six weeks during five months and eighteen days (for severe flowing), at the end of which time the placenta passed away. It was enveloped in a well-organized membrane, and was well preserved.

The patient never suffered any inconvenience save at the time of flowing.

## Hospital Reports.

### BOSTON CITY HOSPITAL.

Reported by DAVID W. CHEEVER, M.D.

#### REPRODUCTION OF THE TIBIA.

CASE I.—*Excision of the entire Diaphysis and the lower Epiphysis of the Tibia from a girl of 13 years, for Suppurative Periostitis, followed by Regeneration of the Bone, and a useful Limb.* (Service of Dr. CHEEVER.)

July, 1868.—M. F. M., aged 13 years, after passing successively through scarlet fever and measles, was left reduced and feeble, and in April last, three and a half months ago, she began to experience constant and excessive pain in the right leg. Soon, a spontaneous opening occurred, giving exit to thin pus. The disease went on, other openings formed, and the child became much exhausted. On her admission to the Hospital the entire length of the tibia was riddled with sinuses, seven or eight in number, and all leading to denuded bone.

Under ether, an incision was made over the crest of the tibia, from the tubercle of the ligamentum patellæ to the ankle-joint. The entire shaft of the bone was found bare of periosteum, smooth, white and dead. A red and thick periosteal membrane lay on either side, and was attached only to a ridge on the posterior surface of the tibia. Even from this it was separated by the handle of the scalpel. A chain saw was passed under the upper part of the tibia, and the bone sawed just below the junction of the upper epiphysis and the shaft. On raising the shaft from its periosteal bed it was now found that the lowest sinus penetrated the

ankle-joint, and that the lower articular surface of the tibia was seriously eroded and diseased. The internal lateral ligament was divided, the capsular ligament cut across subcutaneously, and the bone dissected out from its attachments to the fibula and the astragalus. Both the latter bones were found healthy. The ankle-joint was thus freely opened. No vessels required ligation, the hæmorrhage being checked with ice-water. The thickened periosteum lined the entire wound, which was left open to granulate.

The leg was laid on its outer side, in a tin splint; and the wound kept wet with liq. sodæ chlorinatæ, diluted with five parts of water.

The entire length of tibia removed was nine inches.

On the second day, suppuration began, and healthy granulation soon followed. The patient's condition was eminently satisfactory, the shock from the operation being trivial, and the relief from the removal of the diseased bone, marked.

On the seventh day the granulations were becoming so exuberant that the sides of the wound were approximated by adhesive strips.

On the eighteenth day, new bone could be traced beneath the whole line of granulations, feeling, under the finger, as thin ice does when we put the foot on it to test its thickness. The new growth of bone kept pace with the healing process, so that when, after eight weeks, the wound had entirely closed over, the new shaft had acquired considerable firmness; and there was also mobility in the ankle-joint.

It was not until five months after the operation that the patient was allowed to put the foot to the ground, and then an apparatus was applied. This had a two-fold object; to lengthen the limb, and to evert the foot.

The leg was three-fourths of an inch shorter than its fellow on the inside, and one-half an inch on the outside, and the ankle and foot inclined to the position of talipes varus. A curious change had taken place in the fibula, one which Ollier says always follows excision of the diaphysis of the tibia.

The fibula was dislocated from its articulation with the upper epiphysis of the tibia, and drawn upwards, so that the head and styloid process of the fibula were one-half inch nearer the anterior superior spine of the ilium, than on the other leg. This change was due to the contraction of both the flexor and extensor muscles, without any resistance from the shaft of the tibia,

Vol. III.—No. 8a

the main column of support. The oblique articulation of the upper end of the fibula also favors dislocation upwards.

It is now eight months since the operation, and improvement has been uninterrupted. An apparatus, made by Dr. Nathaniel Greene, 2 Tremont Temple, Boston, combines the long Sayre's splint with Scarpa's shoe. This is kept firmly applied, and with it, the patient now begins to walk. The new bone is as wide as the old one, above, for a space of four inches, and about as firm. Below, it tapers down, and becomes more flexible. There is a fair mobility in the ankle-joint. The sole comes squarely to the ground, and the foot is turning out.

There seems to be no reason to doubt that a perfect restoration will be effected, and a most useful limb result. There never has been any trouble from the ankle-joint. The patient is growing tall and strong, and moves about continually.

CASE II.—(Service of Dr. BUCKINGHAM.) The patient, a girl of eight years, had suppurative periostitis, and denudation of the diaphysis of the tibia. About five inches of the shaft were dissected out, and the extremities cut through with the chain-saw. Recovery was excellent and continuous. A good limb resulted.

That removals of the diaphysis, and especially both diaphysis and lower epiphysis of the tibia are rare, is proved by the small number of cases, five in all, collected by Ollier, of Lyons, in his great work on the "Regeneration of Bone."\*

These cases are so interesting, that we extract from them at some length.

"We find the most remarkable and most complete reproduction of bone in the tibia. Without recurring to older observers, we shall confine ourselves to the cases in which sub-periosteal operations have been done methodically and designedly. We find various examples of affections of different kinds, which have required operation. Larghi, and Crens-y-Manzo, have operated for chronic ostitis; Langenbeck and Neudörfer for compound fractures; Jambon and Aubert, Holmes and Leutenneur for acute periostitis.

"OBSERVATION XXX.—Sub-periosteal resection of four inches of the lower end of the tibia for suppurative ostitis, with separation of the epiphysis and invasion of the ankle-joint, by Jambon and Aubert, of Mâ-

\* *Traité Experimentale et Clinique de la Régénération des Os, et de la production artificielle du Tissue Osseux.* Par L. Ollier, Chirurgien en Chef de l'Hôtel-Dieu de Lyon. Tome Second. Partie Clinique. Paris: Victor Masson et Fils. 1867.

con. Excellent reproduction of bone; and perfect restoration of the functions of the limb.

"Michael Duvert, 21 years old, had numerous fistulous openings on either side of the leg, giving exit to an abundant suppuration, with severe pain, fever and vigilance. Having been chloroformed, a primary incision along the fibula assured the operator that this bone could be saved. The diseased portion of the tibia was freely uncovered, and the bone divided by a chain-saw four inches above the ankle-joint.

"The inflamed and thickened periosteum was easily detached throughout. The bone, carious in its entire diameter, broke into two fragments, of which the lower, representing the epiphysis, was detached with some difficulty from the bones of the tarsus, which were found quite healthy. The consequences of the operation were very fortunate.

"After a free suppuration, the edges of the wound united by granulations, starting from the bottom. In less than two months the sinuses were closed, and a firm resistance, under pressure, was felt. Under the use of tonics and a full diet the bony repair proceeded rapidly. In less than six months he walked with the aid of one cane; and in ten months he was discharged.

"Four years having passed, the young man has worked constantly at his trade of shoemaking; his gait is easy, and he often walks twenty miles a day. Although there is shortening, there is no deformity. The portion of tibia removed has been entirely reproduced; a slight projection corresponds to the malleolus.

"This operation cannot be classed among removals of a sequestrum. There was no movable bony fragment. The diaphysis had to be sawn, and the epiphysis held to the fibrous tissues which are inserted into it in the normal state.

"OBSERVATION XXXI.—Suppurative periostitis of the whole diaphysis of the tibia, with grave constitutional symptoms. Extraction of the diaphysis before the reossification of the periosteal sheath; by T. Holmes, of London. Recovery—renewal of bone—shortening of the limb.

"The patient was 10 years old. Under chloroform it was found that the tibia was denuded above, below and behind, at every point that the finger could reach. A long incision having been made over the tibia, separation of the periosteum from the posterior border was easily accomplished by a sound guided by the finger. The chain-saw passed under the tibia divided it near

its upper extremity; the section, seized with strong forceps, was detached from the upper epiphysis. The same manœuvre was repeated for the lower end. Thus the entire diaphysis was removed, measuring seven and one-third inches. The limb was placed in a fracture-box. Six weeks later, when consolidation was already advanced, shortening was observed. It was then seen that the head of the fibula was unusually prominent. Efforts to lengthen the limb were made without avail. After six months he was exhibited to the Medical Society, in perfect health, with the limb solid and inflexible. The tibia was replaced by a bony mass of the same form, though thicker, and less regular. There was an inch and a half of shortening. He walked well with a cane.

"OBSERVATION XXXII.—Suppurative periostitis of the diaphysis of the tibia, with severe constitutional symptoms. Removal of the whole diaphysis by Lentenneur. Recovery.

"The patient was 12 years old. Denudation of the tibia the whole length of the shaft. Articulations healthy. Operation the 8th of August. Incisions above and below, the middle third of the skin being left untouched. By a to-and-fro movement the whole diaphysis was extracted. The periosteum was thickened. By the end of September there was ossification under the edges of the incisions above and below; no repair in the middle, where the skin was uncut. Marked shortening of the limb, and partial dislocation of the head of the fibula. In the month of March following, the upper and lower cicatrices were united by an incision, and the periosteum found reduced to a little fibrous cord. This was incised, and gouged, and a seton inserted. Having been retained three weeks, this restored the osteogenic properties of the periosteum, and the upper and lower spurs of bone lengthened, and approached each other. At this time the child left the Hospital.

"OBSERVATION XXXIII.—Sub-periosteal resection of the diaphysis of the tibia for chronic ostitis, to an extent of eight inches, by Larghi. Regeneration of the entire fragment removed.

"John S., 12 years of age, from Refran-core, operated upon Dec 4th, 1853, discharged April 30th, 1854.

"Operation.—The numerous openings from the bone to the skin are clear indications of the extent of the evil which affects this bone; it is actually riddled. Below, the sinuses were very near the joint. However, it was found that the disease did not penetrate into the tibio-tarsal joint. The

tibia is affected throughout its entire length; the disease appeared to stop at the apophyses, which often have a separate vitality from the rest of the bone. The mode of operation was very simple, a straight incision being made over the tibia, from one end to the other, and down to the bone. Two transverse incisions, through the skin only, were made above and below.

"On examining the lower part of the tibia it appeared entirely eroded. Experiencing some difficulty in introducing the chain-saw, I cut away the bone with bone-forceps. The upper part was quite isolated, and removed with the chain-saw. Before commencing the resection I pushed back the periosteum below the ligaments of the ankle, and preserved it entire, without wounding either tendon or nerve. The periosteum was thickened and red.

"Four months and a half after the operation the condition was as follows: the patient was up and moving on the diseased limb. The new tibia was quite hard in its upper three-fourths. The lower fourth, at first soft and flexible, had become firm and unyielding. The new tibia was regular in form, and larger above, than the old one. The patient left the Hospital two weeks later.

"OBSERVATION XXXIV.—Ulcerative osteitis of the tibia. Sub-periosteal resection of the entire diaphysis by Creus y Manso, of Grenada. Complete regeneration of the part removed. Slow recovery, with restoration of the functions of the limb.

"The patient, a boy of fifteen years, entered the Hospital on the 10th of April, 1861, for an acute inflammation of the tibia, with numerous sinuses. Operation on the 10th of June. A long incision was made, parallel to the crest of the tibia, from the tuberosity to within an inch and a half of the ankle-joint—a transverse incision, through the skin, at each extremity. The dissection between the bone and the periosteum was made with the handle of the scalpel. Having reached the posterior edge of the bone, a curved director was passed beneath it, and the chain-saw used. The entire diaphysis was removed. The epiphyses were sound. The wound was bordered by periosteum. There was no hæmorrhage. The portion removed measured seven and a half inches.

"On the 20th, the limb was somewhat stiffened, and examination showed that the work of regeneration had begun.

"The 2d of September, the lower wound was completely cicatrized, and at this point the union of the new bone with the old was

complete. It was not so with the upper part, where a sequestrum of old bone was removed, at this date. It was two years before restoration was perfect.

"Since the final results of these extensive suppurations beneath the periosteum is the necrosis of the bone, the operation done in such cases may resemble the simple extraction of a sequestrum; everything will depend upon the time of interference. If we operate early, while the bone is yet alive and vascular, while the periosteum is still adherent to a portion of the surface, we make, in truth, a resection; but if we wait until the diaphysis is isolated on every side, and holds only by weak medullary adhesions, near its extremities; we do nothing but remove a sequestrum.

"It might be asked whether it were not better to wait until the periosteal ossifications were advanced. We have already recommended expectation for the diaphyses, as long as the joints are not invaded. It is to arrest suppuration, and dépôts of pus, and prevent pyæmia, that it appears reasonable to interfere.

"On consulting statistics we find that resections of the diaphysis of the tibia give a smaller mortality than amputations of the leg. Heyfelder gives the following table:

Cause of Resection.	No. of Cases.	Lived.	Successful.	Partially Successful.	Died.
Fractures . . . .	65	47	43	4	18
False joints . . .	11	11	10	1	0
Deformities . . .	16	15	14	1	1
Curvatures . . .	11	11	11	0	0
Organic Diseases .	22	20	19	1	2
Total . . . .	125	104	97	7	21

"Resection of the bones of the leg, with solution of continuity, gave three-fourths of complete success, and one-fourth of partial results. Five-sixths of those operated on lived. These resections give better results than amputations of the leg, of which one-third die; and in primary amputations, one-half are fatal."

THE DEPTHS OF THE OCEAN.—At a recent meeting of the Academy of Sciences, M. Henri Deville invited the members to visit his laboratory at the Ecole Normal, in order that they might inspect the apparatus erected by M. Cailletet, in which fishes are living under a pressure of 400 atmospheres, proving that the greatest depths of the ocean may be habitable.—*Med. T. & Gaz.*

## Bibliographical Notices.

*Treatise on the Diseases of the Ear, including the Anatomy of the Organ.* By ANTON VON TRÖLTSCHE, M.D., Professor in the University of Würzburg, Bavaria. Translated and Edited by D. B. SR. JOHN ROOSA, A.M., M.D., Clinical Professor, &c. &c. Second American, from the Fourth German Edition. New York: William Wood & Co. 1869. 8vo. Pp. 565.

YEARS ago—how many we do not care to reckon up, but long enough ago to change some of us from youngsters into middle-aged men—Dr. E. H. Clarke read a certain paper before the Boston Society for Medical Observation on Diseases of the Ear. In that paper Dr. Clarke took the ground that much of the diagnosis and treatment of affections of the ear might be mastered by the general practitioner. Thinking that what was true then might possibly be true now, we did not send Dr. von Tröltsch's book to an aurist to test by the illumination of his special knowledge, but scanned it for what information we might obtain from it ourselves. We have been rewarded for our pains, and think we have a good manual for our guidance. If serviceable to us, we think the work must be more so to the physician who does not reside in a city where he can send patients to a skilled aurist in the next street. The descriptions and directions are clear, concise and practical. The translator tells us that although this volume is nominally a revised edition of the former one, it is in fact a new work; and that the original has been greatly improved by a thorough revision, while in many parts it has been entirely re-written. *It has an index*, excellent paper, and fair type.—Ed.

*A Hand-book of Uterine Therapeutics, and of Diseases of Women.* By EDWARD JOHN TILLY, M.D., Member of the Royal College of Physicians, &c. Second American edition, thoroughly revised and amended. New York: D. Appleton & Co. 1869. 8vo. Pp. 345.

In perusing this work, we have been struck with the author's candor and impartiality, and his freedom from extravagance of statement. His work is valuable, not simply as giving a list of surgical and pharmaceutical remedies, but as containing a very clear statement of the hygienic and the moral treatment of women's diseases. Bathing, diet, rest, exercise, travelling,

gymnastics, are spoken of in a way that evinces rare common sense. A very good chapter is added, upon the influence of climates, especially hot climates, in relation to uterine complaints.

We notice one statement which is so clearly an oversight that it hardly detracts from the merit of the book. While due credit is given to Dr. Hodge for inventing "one of the best instruments for maintaining the flexed womb in a right position," the author says that "the instrument should apply gentle pressure as high up as possible against, and *in front of*, the ante-flexed or anteverted womb."

We think the book cannot fail of giving great pleasure to its readers, apart from the satisfaction which a complete work of reference naturally gives. D. F. L.

BOSTON: THURSDAY, MARCH 25, 1869.

### CRITICAL REMARKS ON A CLINICAL LECTURE OF PROF. OPOLZER.

WE take great pleasure in placing before our readers the following criticism:—

MR. EDITOR,—At your request, I send you a sketch of the critical remarks that I made at a meeting of the Society for Medical Improvement upon the lecture of Prof. Oppolzer, which appeared in the *JOURNAL* for March 4th—those remarks being founded upon the general impressions I have received from the cases that have occurred here.

The subject of the lecture is one with which we are all quite familiar; numerous specimens of the disease having been shown to the Society at different times, and many of them having been preserved in the College Museum and in our own.

And, in the first place, I would object to the high-sounding term "*Ulcus Rotundum Ventriculi*," as the ulcer is by no means always round, though it is sometimes remarkably so, and always tends more or less to that form. The term "*perforating ulcer*," which appears once in O.'s lecture, and is applied to ulcers that do not perforate as well as to those that do, if I am not mistaken, is also objectionable, as death is sometimes caused by hæmorrhage. The ulcer-

also, may cicatrize, or it may be found in patients who have died of some other disease, and in whom it may never have been suspected. The term "chronic ulcer" is simple and very expressive; and, as it is sufficiently common, it would be well if it were generally adopted.

A large portion of the lecture is taken up with the symptoms of the disease; and epigastric pain, heart-burn and cardialgia, with other symptoms, are well described. It is to be hoped, however, that most cases of cardialgia are not to be referred to it, as Oppolzer seems to think may be the case. "The nutrition," he says, "is often but slightly affected, provided there is no hæmorrhage, and cardialgia does not set in during the night." This last remark certainly requires some explanation.

In two different places he speaks of the "continuous" character of the pain in case of perforation; but this would be a very mild term to apply to most of the cases that have been observed here. On the other hand, the distention of the abdomen, as he has seen the disease when this accident occurs, is much greater, I think, than it has been in our cases. In connection with this remark, however, I would mention a case that happened to be reported to me on the day after I made these remarks to the Society, by Dr. Chas. E. Hosmer, of Waltham. Dr. H. brought to me a fine specimen of chronic ulcer of the stomach that he had recently removed from one of his patients who died of perforation, and who lived for the very unusual period of nineteen days after the accident occurred. In this case, of which a report will be published, the distention after the ninth day was very great, though before that time it was only moderate. To the symptoms of collapse in these cases, Oppolzer makes no reference.

In regard to the size of the stomach, he remarks that it varies; but that, when the ulcer is close to the pylorus, this last contracts, and may cause a dilatation of that organ. I once found the dilatation perfectly enormous when the ulcer was situated upon the pylorus; but, excepting that case, I have never, I think, met with one in

which the size of the organ was in any way remarkable. And, neither, have I seen the slightest appearance of an hour-glass contraction, to which Oppolzer refers, when the ulcer is in the middle of the small curvature. He speaks of the continual contraction of the organ as the ulcer extends; but in ulcers of the largest size, I have seen nothing of the kind. As to a relaxation of the muscular fibres and consequent dilatation of the organ, which is due, as he says, to "catarrh," I should say that the mucous membrane was very generally quite healthy, however we might expect it to be otherwise.

Oppolzer remarks that "most cases of *ulcus rotundum ventriculi*, like chronic maladies of the stomach in general, are combined with tuberculosis pulmonum and phthisis." I should always very much prefer to have my observations agree with and help to strengthen those of others, rather than the contrary; but, with one exception, this statement is certainly utterly at variance with what has been observed here.

Healing by cicatrization is spoken of, and is generally remarked upon by authors as sufficiently common; but I have never happened to see more than two or three times a cicatrix that I thought might be caused by the healing of a chronic ulcer.

In case of perforation, Oppolzer states that the liver is pressed back by the air in the peritoneal cavity, and that there is consequently a resonance on percussion in the region of that organ. In Dr. H.'s case, above referred to, the liver was pushed very far upward and backward; but I do not remember to have seen such a displacement in any dissection, nor have I heard any such reported here. The distention was very great in Dr. H.'s case, as already stated; but how much of it was due to the air in the peritoneal cavity, and how much to a large effusion of pus and to the distention of the intestine may be a question. The peritoneum is not distended by rupture of the stomach, as the pleura is by rupture of the lungs.

When an ulcer forms it seems now to be supposed that the particles of the affected tissue lose their vitality and are cast off;

but it is certainly a great misapplication of an old and well established term to call this process "necrosis."\*

The treatment prescribed for the disease is certainly remarkable. "Sour milk is the chief point; for the cardialgia, give magistery of bismuth (sub-nitrate), with acetate of morphia, or, if the patient is inclined to be constipated, with belladonna." This last is probably given with a view to relax the muscular coat of the intestine, but we should hardly like to give enough of the drug to produce such a marked constitutional effect, when we have so many perfectly safe laxatives at our command. If the "magistery of bismuth" is nothing more than the sub-nitrate, with which the Germans as well as ourselves are probably so familiar, why should not he have used that term, in his own language, instead of one that savors so strongly of the old days of alchemy? The brackets are from the original, and not the translator's. In regard to the term "pills" of ice, which, as Dr. L. tells me, is translated literally from the German, it certainly is no improvement upon the "small bits of ice" which we are in the habit of giving, as well as Oppolzer, in cases of vomiting.

When peritonitis occurs (from perforation, of course), local bleeding and cold applications to the epigastrium should be resorted to without delay. If Oppolzer imagines that there is the slightest chance for his patient under such circumstances, let him by all means use active treatment; but, here, I believe, it is considered as so nearly certain that the patient will die, that any curative measures that in any way tend to his discomfort, are looked upon as nothing less than cruel. We give opiates, in some form, as our principal active means of treatment; and it is particularly to be remarked that Oppolzer does not allude to the use of them when the distressing accident occurs.

"For heart-burn, bicarbonate of soda, chalk, magnesia, and conchæ præparatæ; when the last is used, the patients often

have disagreeable sensations in the stomach, as the article is entirely composed of minute pointed fragments;" and well they may, when he uses so coarse a remedy. He then goes on to say "(Dog's dung has been employed for the same purpose)." The parentheses are from the German; but what they signify does not appear, unless they may serve as a partial cover for the indecency of the idea. It is well known that dogs are in the habit of chewing up bones, and discharging the fragments after the nutrient matter has been extracted; but what particular advantage the phosphate and carb. of lime can have after having been squeezed through a dog's intestines, over the delicately prepared sub-acids of modern pharmacy, is not to be conceived. No one, who had a proper sense of decency in his nature, could prescribe for a fellow-creature so filthy an article as the one referred to; and it is to be hoped that when he does order it for his patients he throws over it the mantle of a foreign language, in which throughout his lecture he indulges so freely.

It was remarked at the meeting of the society that these lectures are probably reported by some attendant upon them, and that Oppolzer ought not to be held responsible. But the editor of so respectable a Journal as the *Allg. Med. Zeitung* must know who he employs, and we cannot suppose that he would accept a report from any but a competent person. It seems as if it could not be very far out of the way; and, in conclusion, I would say that if the present is a fair specimen of the lectures of this very distinguished Professor in what I believe is considered as the very best school for clinical instruction in Europe, I think that, so far as clinical medicine goes, the young men who go to Vienna might as well stay at home and save their money.

Yours very truly,

J. B. S. JACKSON.

March 10, 1869.

NOTES FROM THE GAZETTE HEBDOMADAIRE DE MEDECINE ET DE CHIRURGIE.

SINCE 1862, says this journal, the attention of Dr. Bowditch, of Boston, has been directed to soil-moisture as a cause of phthi-

\* *Necrosing*, we are informed by the translator, is the German word used by Oppolzer. To translate it literally we should have to found a verb, as we understand the matter, on the term *necrosis*. The participle of that verb would be *necrosing*.—Ed.

sis; a close relation being established between the meteorological condition and the disease. At the same time, says the *Gazette*, Dr. Buchanan arrived at the same conclusions in England, without being cognizant of the labors of his American cotemporary. We have already claimed for Boston the priority in this matter.

The English Government have just sent two commissioners to India—Drs. Cunningham and Lewis—to study the causes of cholera at its very source.

*A Pathological Survey of Mexico.*—Inflammations of the respiratory apparatus cause a little more than a tenth part of the deaths. M. Poindet (in his book entitled *Le Mexique au point de vue médico-chirurgical*) thinks the rarefaction of the air is a predisposing cause. Abscess of the liver is common. Marsh miasmata produce a considerable number of deaths; but mortality is obviously not a reliable indication of the frequency of the malady. Deaths by dysentery are in the proportion of about 69 to 1000 deaths from all causes. Congestion and hæmorrhagic flux are frequent, principally in autumn. Typhoid fever presents the same characteristics as in France. Finally, the yellow fever does not show itself on the elevated table lands.

*Académie des Sciences. Experiments in Inoculation, demonstrating that Malignant Pustule and the Blood of an Animal affected with Anthrax do not lose by Desiccation their virulent Property.* By M. RAIMBERT.—In a communication by M. Bouley to the Academy the 18th of February, upon the *mal des montagnes*, which he identifies with anthrax, I read, says M. R., the following conclusion:—That the blood of a subject affected with anthrax, which contains bacterids in great quantity, loses its virulent property by desiccation, and does not recover it by dilution in water, although the bacterids remain quite visible. This conclusion, M. Raimbert goes on to say, is entirely opposed to the results he has obtained by inoculation performed with fragments of malignant pustule and with dried blood from an animal having anthrax. The cases and experiments referred to by their reporter, prove, in his opinion, that a fragment of malignant pustule, dried, at least upon the surface,

inoculated into a rabbit; and also the blood of an animal tainted with anthrax, and containing bacterids, inoculated into a rabbit or a guinea-pig (the blood having been evaporated to dryness, or first dried and then diluted with water), are fatal to these animals.

Langerhaus has been experimenting on the nerves of the skin, with reference to their terminations, and has arrived at results analogous to those of Cohnheim as to the nerves of the cornea. Like Cohnheim, Langerhaus has made use of chloride of gold, which gives a reddish color to the nerves. The white nervous filaments, according to him, pass through the cutis, and terminate in a special corpuscle situated in the epithelium, which corpuscle gives rise to slender filaments. The ultimate termination is thus in the midst of the epidermis. Langerhaus insists on the accuracy of his investigations, declaring that the corpuscles cannot be corpuscles of connective tissue, nor epithelial elements; but are formations of nerve structure. In the new-born child, he adds, these terminal corpuscles form a sort of regular layer, the elements of which are separated by two, three or six epithelial cells. In a millimetre square, five hundred (500) could be counted. At the extremity of a papilla there were found as many as ten. Such richness of distribution he thought indicated an important physiological function, which should perhaps be referred to the domain of the common sensibility.

Prof. Krause explains the *cause of the pain in anal fissure*, by the anatomical distribution of the nerves in that region. He has found that a great number of nervous filaments with terminal corpuscles are distributed to the long papillæ of the columns of Morgagni.

In the *Archives de Physiologie* we find an account of experiments on the *Influence of Irritation of the Cutaneous Nerves upon the Temperature of the Limbs*; by Drs. Brown-Séquard and J. S. Lombard.

One of the experimenters being seated and keeping perfectly quiet, in a chamber the temperature of which remained constantly the same, subjected first one limb and then another to the irritation of pinching, while

the temperature of the limb experimented on, or of that on the opposite side, was observed by means of the thermo-electric pile.

The results of the experiments are thus summed up :

1. The irritation of the skin of a limb by pinching is soon followed by elevation of temperature. 2. This irritation produces in the corresponding limb on the opposite side a diminution of temperature. 3. The pinching of the skin of one of the inferior extremities often produces a change of temperature in both upper extremities—diminution in that of the limb on the opposite side, elevation in that of the corresponding side. 4. All these phenomena of diminution or of exaltation of temperature are in all probability effects of vascular contraction or dilatation, brought about by reflex action.

#### NOTES FROM THE UNION MEDICALE.

*Tardieu on Poisonous Coloring Matters of Textile Fabrics.*—M. Tardieu, in a note supplementary to his memoir on poisoning by coralline, says that without mentioning the mineral reds, vermilion, and other dyes which are not in question, the principal organic colors which may be fixed upon textile fabrics are six in number, viz., madder, cochineal, murexide (derived from murex), saffron (*carthamus*), aniline red, coralline. The three first can be fixed on cloth only by means of metallic oxides called mordants. Thus the madder red is grounded upon alum, or alum and tin; cochineal red upon tin; murexide red upon oxide of mercury or lead, often dangerous to the workmen who handle it. The three last of the list of six coloring agents are fixed upon tissues without any mordant. But it is important to remark, he says, that the red of aniline is now prepared exclusively by means of arsenious acids; and that the commercial aniline reds contain always a certain quantity of arsenic. It is to this poison, he adds, that are to be attributed the symptoms presented by certain workmen employed in the manufacture of aniline red. M. Tardieu was informed by M. Bidard, of Rouen, that coralline had been employed in dyeing calico, the agent having been rendered soluble in water. The fabric, however, not

being worn next the skin, there was no danger from it.

At the Société Médicale des Hôpitaux, Dr. Desnos read a case of hæmorrhagic effusion into the medulla oblongata, attended with albuminuria and with the symptoms of uræmia. At the autopsy, a collection of blood was found in the medulla oblongata of the size of a hazle-nut. Besides the fluid blood, there was a clot of the size of a pea. The kidneys and all the other organs were sound, except that the lungs were congested.

M. Mattei points out a cause of retention of urine in females after delivery, which he thinks consists in a wrinkling of the urethra. That canal being put upon the stretch during parturition, is relaxed after delivery, and easily becomes folded upon itself. Catheterism performed once or twice is all that is necessary to remove the difficulty. If that operation be required for a long time, it shows that there is not merely a wrinkling of the urethra, nor a contusion of it, nor inertia of the bladder, but paralysis of the latter organ.

Among the authorities who have spoken favorably of bromide of potassium in large doses for epilepsy, the *Bulletin Générale de Thérapeutique* mentions Sir Charles Locock, Dr. Radcliffe, Dr. Williams (of the Northampton Asylum), Dr. Robert McDonnell; MM. Brown-Séquard, Blache, Bazin, J. Besnier, A. Voisin and Fabret. M. A. Voisin gives from 4 to 11.50 grammes per day, the last figure being reached by gradual increase. He says the drug is of no use in epilepsy connected with cerebral lesion.

**ORIGIN OF THE ROUND ULCER OF THE STOMACH.**—This is commonly attributed to the occlusion of an artery of the stomach, and the perishing of a certain portion of tissue in consequence. M. Roth (in *Virchow's Archiv*, 45 B. 2 H. 68) describes numerous experiments, made chiefly upon rabbits, in which arterial branches in the walls of the stomach were tied. The mucous membrane was found normal, two or three days after the operation, in every instance except where a portion of it had accidentally been included within the suture. In other cases fragments of nitrate of silver (some as large

as 0.3 grammes) were administered in pills; and in every one of this series of experiments ulcerations were found, situated on the lesser curve and the posterior wall, mostly round, sometimes oblong, and very variable in size. Many superficial erosions also were found. The author infers that the round ulcer, in man, may have a similar origin.—*Allg. Med. Central Ztg.*

D. F. L.

The following paragraph is from among the "notes and queries" of the *London Medical Times and Gazette* for Feb. 20th, 1869. The extract referred to as in our issue of Jan. 7th, is credited to the *Dental Cosmos*. Will that Journal furnish the information desired? We suppose the querist may wish to know how many drops of the mixture are to be applied at each session.

**IODINE AND ACONITE IN PERIODONTITIS.**—Professor Abbott writes:—The best remedy, and the one that works the most conveniently for periodontitis, I have ever used, is a mixture of equal parts of official tincture of iodine and tincture of aconite root applied to the gum around the roots of the tooth with a camel's hair brush, or a portion of cotton-wool at the end of a stick. I have been using it for a year, and have not found it fail. I apply it, in the early stages of the inflammation, once in the twenty-four hours, and in very severe cases twice.—*Boston Journal*, January 7.—(*Quære*: What dose of aconite is administered?)

From the annual report of the Resident Physician of the Massachusetts General Hospital, for the year 1868, we learn that the number of patients in the Hospital, January 1, 1868, was 108—paying, 39; free, 69. Admitted to the Hospital from Jan. 1, 1868, to Jan. 1, 1869: patients paying board, 463—males, 333; females, 130. Patients paying part of the time, 31—males, 22; females, 9. Patients entirely free, 771—males, 445; females, 326. Total, 1265—males, 800; females, 465. Discharged during the year: Well, 757—males, 458; females, 299. Much relieved, 103—males, 61; females, 42. Relieved, 155—males, 98; females, 57. Not relieved, 64—males, 37; females, 27. Not treated, 71—males, 50; females, 21. Dead, 85—males 67; females, 18. Insane and eloped, 11—males, 7; females, 4. Total 1246—males, 778; females, 468. Number of patients remaining Dec. 31, 1868, 127—males, 76; females, 51.

Paying, 31; free, 96. Medical, 66; Surgical, 61. Twenty-three per cent. of the free patients were female domestics; twenty-two per cent. were laborers; fifteen per cent. were mechanics; and seventeen per cent. were children.

The average time of paying patients was 3 weeks; and that of free patients,  $3\frac{2}{3}$  weeks. The proportion of ward beds occupied by free patients was about  $\frac{2}{3}$ ; by paying patients, about  $\frac{1}{3}$ . About twenty per cent. of the paying patients occupied private rooms.

**Out-patients.**—Five thousand two hundred and sixty-four persons have been treated as out-patients, receiving advice, medicine, surgical attendance and treatment.

**THE FUNCTION OF THE BILE UNKNOWN.**—Dr. Letheby (*Chemical News*), in an article on "Food," states that the true function of the bile is unknown; perhaps it aids in neutralizing the acid peptones from the stomach; perhaps, also, in emulsifying fat; and it may be that it helps the digestion of starchy foods. Lehmann thinks it is a rich residuum from the manufacture of blood globules in the liver, and that it is secreted into the alimentary canal, only to be reabsorbed into the blood. Mr. Lee, also, is of opinion, from his examination of the fetal liver, that it separates a highly nutritious substance from the fetal blood, which is elaborated in the intestines. Its functions, however, are manifestly obscure.

The bile is a complex liquid, consisting of biliary acid (taurocholic, glycocholic, &c.) in combination with soda. Its reaction is slightly alkaline, and it contains about fourteen per cent. of solid matter, not less than twelve of which are organic.—*Medical Record*.

From a notice in the *Dublin Medical Press and Circular* of Dr. Murchison's new book on Diseases of the Liver, &c., we extract the following:—

"Take, for instance, the question of the action of mercury on which Dr. Hughes Bennett has been engaged in experiments for the British Medical Association, and whose conclusions thereon so surprised the great body of practitioners. Dr. Murchison has evidently carefully weighed the evidence, and he has come to a conclusion which is likely at present to receive the assent of the majority. He thinks that "mercury and allied purgatives probably produce bilious stools by irritating the upper part of the bowel, and sweeping on the

bile before there is time for its absorption." He recognizes the fact that articles of food frequently give rise to similar effects, and thinks that their action is precisely similar. From this we might suppose that other purgatives should be substituted more frequently than they are, and assuredly this view supports the American preference for podophyllin, or, as it is called sometimes in the States, "vegetable calomel." We could certainly say much in its favor. Dr. Murchison considers calomel of great use in congestion of the liver, but if it increased the secretion of the bile, it would have an injurious effect. He thinks it likely that "irritation of the duodenum by purgatives, may be reflected to the gall-bladder, and cause it to contract, and that the evacuation of the viscus may account in part for this increased quantity of bile in the stools." Dr. Murchison's is a handy sized volume. The former half treats of enlargements of the liver, under the division of painful and painless enlargements. The latter includes gall-stones, jaundice, hepatic pain, contractions, and abdominal dropsy. The cases upon which the lectures are founded are well selected and carefully related. Their study is likely to lead to more careful diagnosis and treatment."

EXTRACTS from a Clinical Lecture on the Treatment of Carbuncle. By JAMES PAGET, D.C.L., F.R.S., Surgeon to St. Bartholomew's Hospital:—

"First, with regard to the incisions made in carbuncles. The ordinary plan, still recommended by some, is, as soon as a carbuncle is seen, to make two incisions crucially from border to border. It is said that they must go even beyond the edges of the carbuncle into the adjacent healthy textures. I have not followed that method of practice very often, but I have followed it quite often enough to be sure that it does not produce the effects which are commonly assigned to it. It is commonly said that if you will thus make crucial incisions into a carbuncle, you will prevent it spreading. If you can find a carbuncle two or three days old, and cut it right across in both directions, I think it very likely that you will prevent it spreading. But even therein is a fallacy; for there is no sign by which, on looking at a commencing carbuncle, you can tell whether it will spread or not, whether it will have a diameter of an inch, or of three, six, or ten inches. . . .

"Then it is said that carbuncles are relieved of their pain if they are thus very

freely cut. Here, again, however, is only a partial truth. A carbuncle of two or three days' standing, which is hard, tense, and brawny, is very painful; and cutting it will relieve, in many cases, a considerable portion of the pain. But after this, when the carbuncle begins to soften, and when pustules begin to form upon its surface, and pus in its interior, it ceases to be painful of its own accord, and without incisions. Thus there are two distinct stages of carbuncle in reference to the pain; the early stage, when it is hard and still spreading, and is generally intensely painful, and the latter stage, in which that pain nearly ceases. A carbuncle divided in the first stage, in the first two or three days of its existence, may be relieved of some of its pain; if divided in the later stage, what little pain may exist is altogether unaffected by the cutting. And even cut as you may, you cannot always put aside the extreme pain that a carbuncle sometimes has, even to its later time.

The third point is stated thus, that by the incision of carbuncles you accelerate their healing, giving facility for the exit of sloughs. But herein is the greatest fallacy of all. When the cutting of carbuncles was more customary in this Hospital than it is now, when I did not cut them, and some of my colleagues did, I used to be able to compare the progress of cases cut and of cases uncut, and time after time it was evident that the cases uncut healed more readily than those cut. . . . Indeed, it by no means always follows that the whole carbuncle, or its whole base, sloughs. Carbuncles, if not divided, not unfrequently only suppurate about their centres, and slough only in their central parts, and the borders merely clear up by the softening and dispersion of the inflammatory products in them. In every case of that kind you save greatly the amount of healing which has to be gone through. Nay, in some cases carbuncles completely abort. . . .

On these three points, which are the grounds that have been assigned as reasons for cutting carbuncles, I have now given you the evidence on which I have ceased from the practice. I fully believe that crucial incisions do not prevent extension; that it is only a limited set of cases in which the incisions diminish pain; and that with regard to the time that is occupied in healing with or without incisions, the healing without incisions is very clearly and certainly a great deal the quicker.

The kind of incisions that I have been speaking of is the old plan of crucial inci-

sions. Another method which I have occasionally tried, but of which I can only state the same general results, is that of subcutaneous incision. This has been supposed to have the same general effect as the other; and I think that the same general conclusions may be drawn respecting it; that it is a measure unnecessary in the treatment of carbuncle, and that it retards rather than hastens the healing."—*Medical News and Library*.

EXTRACTS from a Valedictory Address delivered at the Medical Department of the Georgetown (D. C.) College, March, 1869, by FRANK COWAN, M.D., author of the "Runic Inscription," &c. :—

"LADIES AND—to wed kindred Saxon-English words—LORDS, LASSIES, AND LADS,—Once upon a time the greatest man and the greatest ape were very neighborly—a flea might have hopped from the one to the other and found his brothers on each. This greatest man then did all his work himself—was, as far as crafts then went, a jack at all. He killed the bear, the elk, and other deer, himself; eared the earth to earn his bread, himself; wove, of willow-withes, of rush, and thread, his hurdles, mats, and cloth, himself; smoothed and shaped, of wood and stone, of shell and bone, his bows, knives, spears, and other weapons, himself; wrought, of skins, of bark and boughs, his boats and boathes, his hovels, and houses, himself; and he likewise HEALED himself—that is, made himself *hale* or *whole*—when sick and sore.

"Here writhes a wry-necked wight, wrecked and wretched, in wrath wreaking on himself the wrongs wrought by himself, now wringing and wrenching his wrists, now wrangling and wrestling with a wraith wreathed with wrack—lo! and a dwarf leaps from a poppy-head and soothes to a sleep, sound and sweet, the stark and staring madman! Here lies a wounded warrior, his shoulder shot and shattered, riving the very welkin with his shrieks—lo! and a foggy elf floats from a bottle and breathes a mist which melts the ruthless rack of Pain into a downy bed on the bosom of Ease! Here swells a seething sea of small-pox, its loathsome waves welling up till they overwhelm, wash, and wear away the loftiest land of life—lo! and a tiny dwarf, from the teat of a cow, swallows the fiery flood, leaving barely a drop to blister the arm of a babe!"

CAST IRON vs. SHEET IRON FOR STOVES.—General Morin related some comparative

experiments which had been performed by M. Carret, and which, he said, corroborate his theory. Thus, after having remained during one full hour in a room heated to 40° (centigrade) by means of a sheet-iron stove, M. Carret perspired abundantly, got a good appetite, but felt no sickness whatever; he had obtained the same result with an earthenware stove; but the experiment, when performed during only one-half hour with a cast-iron stove, had brought on intense headache and sickness.—*London Lancet*.

HYDROGENIUM—A NEW METAL.—Professor Graham, Master of the Mint, has just read before the Royal Society (January 7, 1869) a very remarkable memoir "On the Relation of Hydrogen to Palladium," in which he brings forward strong evidence in favor of the metallic nature of hydrogen. The view is by no means original, but no such strong evidence in its favor has ever previously been adduced.

Professor Graham gives the name *hydrogenium* to the assumed highly volatile metal of which he regards hydrogen gas as the vapor. The chemical properties of hydrogenium differ from those of ordinary hydrogen. The palladium alloy, which contains hydrogenium, precipitates mercury and calomel from a solution of chloride of mercury (corrosive sublimate) without any disengagement of hydrogen—that is, hydrogenium decomposes chloride of mercury, while hydrogen does not. Moreover, hydrogenium unites with chlorine and iodine in the dark, reduces per-salts of iron and some other metals into proto-salts, and has considerable deoxidizing powers, and, in short, seems to be the active form of hydrogen, as ozone is of oxygen.

"The general conclusions," says Professor Graham, "which appear to flow from this inquiry are that in palladium fully charged with hydrogen, there exists a compound of palladium and hydrogen which may approach to equal equivalents; that both substances are solid, metallic, and of a white aspect; that the alloy contains about twenty volumes of palladium united with one volume of hydrogenium; and that the density of the latter is about 2, a little higher than magnesium (which is 1.743), to which hydrogenium may be supposed to bear some analogy; that hydrogenium has a certain amount of tenacity, and possesses the electrical conductivity of a metal; and, finally, that hydrogenium takes its place amongst magnetic metals."—*Medical Times and Gazette*.

## Medical Miscellany.

**A VALUABLE COLLECTION FOR SALE.**—A large and superior collection of original illustrations by the late Prof. Türek, of Vienna, comprising 777 water-color paintings of life size, and illustrating the diseases of the larynx and pharynx, as seen with the laryngoscope or from pathological specimens, is for sale by the family of the Professor. The paintings were executed by Drs. Ellfinger and Heitzmann in the first style of the art. A history of each case is annexed. Will not some member of the profession so far render himself a benefactor of his brethren as to purchase the collection, that we may have it among us. F. H. B.

From the Report of John W. Sawyer, M.D., Superintendent of the Butler Hospital for the Insane, Providence, R. I., we learn that during the year 1868 there were admitted 80; discharged, 61; whole number under care, 211; recovered, 26; improved, 15; unimproved, 12; died, 8; remaining at the end of the year, 150. From 1848 to 1868 inclusive, there were admitted 1,380; discharged, 1,230; recovered, 465; improved, 342; unimproved, 127; died, 290.

The subject of localization of faculty in particular parts of the brain was again discussed at the Medical Society of London on Monday night in the debate on a very able paper read by Dr. Day, of Stafford, "On Injuries of the Brain and their Consequences." Dr. Day has passed most previous writers in pronouncing against the localization hypothesis, and certainly he adduced cases and facts which, in our present knowledge, are utterly irreconcilable with that hypothesis. He brought forward, for instance, the history of a man who for a long time carried the breech of a gun, a piece of iron weighing two ounces, in the brain, but who showed no indications of loss of any special faculty. Dr. Boyd adduced other examples in support of Dr. Day's view of the possibility of disorganization of portions of brain without symptoms; while Dr. Thudichum, point-blank, disputed the proposition. These extreme differences of opinion show how much we require a sounder physical knowledge of the brain and its functions.—*Med. Times & Gaz.*

**ACCOUNT OF A FAMILY WITH WENS ON THE HEAD.** By PAUL F. EVE, M.D., Professor of Surgery, Missouri Medical College.—I propose to report some striking facts regarding atheromatous tumors under the scalp, which I met with in a family near Augusta, Ga., while stationed there during the war:—

1. Their gregarious or multiple character—a dozen having been removed from one head.
2. Their hereditary tendency—a grandmother, mother, son (my patient), two sisters and three daughters, all having presented these wens on the head.
3. The great size of some of them—one was nearly as large as a small orange or common apple.
4. The conversion of the contents of some of them into a puriform fluid.

*St. Louis Medical Reporter.*

**A SINGULAR DISEASE.**—Before the London Obstetrical Society, Mr. Heckford recently exhibited the generative organs of a child aged ten months, in which the vagina was enormously dilated, and occupied by villous growths of a medullary character. The rectum, bladder and urethra were normal. The os uteri opened into the upper wall of the vaginal sac. The disease had lasted for about four months, and the child died shortly after its admission into the East London Children's Hospital.—*Medical Record.*

At the last annual meeting of the Medical Society of the State of New York, Dr. March read a paper, entitled Spontaneous Lithotomy, giving an account of a case in which a large-sized vesical calculus was discharged through an ulceration in the perinaeum.—*Ibid.*

**HISTORY OF VACCINATION.**—The *Pall Mall Gazette* states that the Russian Government has offered a prize of 3,000 roubles (£400) for the best history of vaccination, by way of celebrating the hundredth anniversary of the introduction of that practice into Russia by the Empress Catherine II. The prize is open to all European competitors, and the history may be written in any modern European language.

## MEDICAL DIARY OF THE WEEK.

MONDAY, 9, A.M., Massachusetts General Hospital, Med. Clinic. 9, A.M., City Hospital, Ophthalmic Clinic.  
TUESDAY, 9, A.M., City Hospital, Medical Clinic; 10, A.M., Surgical Lecture. 9 to 11, A.M., Boston Dispensary. 9-11, A.M., Massachusetts Eye and Ear Infirmary.  
WEDNESDAY, 10, A.M., Massachusetts General Hospital, Surgical Visit. 11 A.M., OPERATIONS.  
THURSDAY, 9 A.M., Massachusetts General Hospital, Medical Clinic. 10, A.M., Surgical Lecture.  
FRIDAY, 9, A.M., City Hospital, Ophthalmic Clinic; 10, A.M., Surgical Visit; 11, A.M., OPERATIONS. 9 to 11, A.M., Boston Dispensary.  
SATURDAY, 10, A.M., Massachusetts General Hospital Surgical Visit; 11, A.M., OPERATIONS.

**ERRATUM.**—On page 115, 1st column, 4th line, omit "which" and insert after "believed" the words *Dr. Charles's instrument.*

**TO CORRESPONDENTS.**—The following communications have been received:—Case of Fibro-plastic Tumor of the Base of the Skull—Cases of Intestinal Calculus.

**PAMPHLETS RECEIVED.**—Fourteenth Annual Report of the Board of Trustees and Officers of the Southern Ohio Lunatic Asylum for the year 1868.

**DEATHS IN BOSTON** for the week ending Saturday noon, March 20th, 114. Males, 59—Females, 55.—Accident, 1—aneurism, 1—apoplexy, 1—disease of the brain, 4—inflammation of the brain, 2—bronchitis, 2—burns, 1—cancer, 2—cholera morbus, 1—consumption, 20—convulsions, 2—croup, 5—cyanosis, 1—diarrhea, 1—diphtheria, 1—dropsy of the brain, 5—dysentery, 1—erysipelas, 1—scarlet fever, 7—typhoid fever, 2—gastritis, 2—disease of the heart, 5—infantile disease, 1—influenza, 1—intemperance, 1—congestion of the lungs, 3—inflammation of the lungs, 11—marasmus, 3—old age, 7—paralysis, 2—peritonitis, 1—pleurisy, 1—premature birth, 2—puerperal disease, 2—teething, 1—trismus nascentium, 1—unknown, 9.

Under 5 years of age, 39—between 5 and 20 years, 15—between 20 and 40 years, 24—between 40 and 60 years, 15—above 60 years, 21. Born in the United States, 74—Ireland, 29—other places, 11.

## Original Communications.

### A CASE OF FIBRO-PLASTIC TUMOR OF THE BASE OF THE SKULL, ASSOCIATED WITH LEUCOCYTHEMIC CHANGES IN THE BLOOD AND SEVERAL GLANDULAR ORGANISMS.

By J. B. TREADWELL, M.D., of Boston.

L. G., æt. 22; height 5 feet 4 inches; weight in health 140 lbs. Sanguineo-lymphatic temperament; fair complexion; brown hair. Always well until commencement of present disease. Mother died of pulmonary phthisis at 49, and one sister of the same disease at 21; otherwise no hereditary disease in family. Married at 19, and gave birth to a child in 1866, which is now healthy and robust; became pregnant again in July, 1867, and aborted in September of the same year. Menses appeared only twice subsequently.

In June, 1867, a small, hard tumor was noticed in the right parotid region, which grew slowly for one year. Subsequently several smaller ones appeared, some of them extending along the submaxillary region. Six months after the appearance of the primary tumor on the right side, a similar one appeared in the same locality on the left side, which in turn was followed by several smaller ones in and about the parotid and submaxillary regions of the same side. She suffered pretty constant and severe pain in and about the original tumor of the right side from the time of its appearance until two or three months previous to the time of her decease. There was never any severe pain in the left side.

Three months since three or four small patches of ulceration appeared in the skin about the right temporal region, and continued in this condition until her death. These ulcerations, however, were very superficial. About two months since the right eye became unnaturally prominent and continued so for some time, when a small discharge of pus took place from two openings—one just under the supra-orbital ridge,

and another just over the inferior border of the orbit—after which the eye resumed its natural position and appearance. About the time the eye became protuberant it also lost the power of vision and motion, and paralysis of the upper lid also occurred. There was no anæsthesia of the globe of the eye or integuments of the head and face. Neither was there any strabismus at any time. All the other special senses were perfect, with the exception of that of smell, which was somewhat impaired. About this time she also became subject to mild clonic convulsions, which generally came on while she was sleeping, and lasted from five to thirty minutes, and occurred several times during the day and night. These continued until the time of her death.

During the last two or three months of her life respiration was performed entirely through the mouth, the nasal passages being obstructed.

During the first six or eight months of the disease the general health suffered comparatively little; subsequently it gave way, and during the last six months of her life she was confined to the house, and for the last two or three months to her bed. She became extremely emaciated during this time.

The appetite was good and digestion well performed throughout the entire duration of the disease, although for some time previous to her death there was some trouble in taking food, owing to a partial closure of the jaws and difficulty of deglutition, both being apparently produced by the pressure of the enlarged glands. There was no diarrhoea at any time. She was patient and cheerful, thinking until a short time before her death that she might recover. She continued to fail, however, becoming more and more prostrated, and died February 23d, becoming comatose three hours previous to her death.

The first time I saw her, 11, A.M., Feb. 3d, 1869, I obtained a specimen of blood from the tip of one of the fingers, which showed the white corpuscles to be considerably increased, there being from twelve to seventeen in a microscopic field of moderate size—the same field showing only one, and

[WHOLE No. 2144.]

VOL. III.—No. 9

in some instances none, in blood from healthy persons. The temperature in the axilla at this time was 97°. The urine was normal. Another specimen of blood obtained Feb. 6th, six hours after the last food had been taken, showed a somewhat larger number of white corpuscles.

Section-cadaveris forty hours after death. Emaciation extreme. Rigor mortis slight. Chest 25 inches in circumference. Arm 4 inches in circumference around biceps. Thigh 7 inches in circumference at middle. A mass of glands in right parotid and submaxillary regions two-thirds the size of the closed fist; one gland, two by two and a half inches superficially, in left parotid region, together with several smaller ones in submaxillary region of the same side.

Head.—Several patches of ulceration in right temporal region involving only the skin, the underlying periosteum being healthy. Considerable serum in arachnoidal cavity. Brain rather less firm than usual, but no real softening. On removing the brain a morbid growth was found, involving the body of the sphenoid and basilar portions of the sphenoid and occipital bones, and extending into the right middle fossa of the base of the skull. The growth surrounded the second, third, fourth and fifth nerves of the right side, and the third and fourth of the left side. The bones involved by the disease were partially destroyed—absorbed. The portions remaining were cut through and the growth found to involve the ethmoid and portions of other surrounding bones, and partially filled the nasal cavities. Three or four mucous polypi occupied the remaining portion of the nares. The right orbital roof was cut through, and the post-ocular cellular tissue and eyeball found to be in a healthy condition, there being no evidence of having been suppuration in the orbital cavity. The morbid growth did not extend into the cavity of the orbit. The dura mater covering the growth appeared to be healthy.

Thorax.—Thymus gland enlarged, three and a half to four inches in length. Two ounces of fluid in pericardium. Heart normal; some coagulated blood in left side, and a firm white coagulum one-half inch in diameter in right ventricle, extending through pulmonary orifice and firmly interwoven with the columnæ carneæ; no blood in right side. Large venous vessels filled with dark colored fluid blood. Lungs pale anteriorly and somewhat congested posteriorly. Slight adhesion of right anterior pleural surfaces. One small cavity one-half inch in diameter in left apex, containing li-

quid pus; no communication with bronchia. Pleural wall of cavity one line in thickness, with no marks of pleuritic inflammation. Small portion of right apex filled with grey granulations, also one small cheesy mass.

Abdomen.—Liver, stomach, spleen and kidneys normal. Right ureter enlarged in diameter and constricted at entrance to bladder. Intestines normal, except one small glandular-looking patch, situated five feet above the ileo-cæcal valve, presenting the shaven-beard appearance of a Peyer's patch. Supra-renal capsules enlarged; three and a half inches in length, seven-eighths of an inch in breadth, and three or four lines in thickness in the thickest portion, and of a yellowish-red color. Pancreas slightly larger than usual. Organs of generation normal. The remains of a true corpus luteum, containing blood-pigment, were found in the right ovary, and a cyst three lines in diameter filled with reddish serum in the left.

Blood taken from the large internal venous vessels contained a relatively large number of white corpuscles, that taken from the splenic vein containing a very large number; one specimen showing fifteen white, to one hundred and fifty red, corpuscles. The white corpuscles in all the specimens examined were of full size.

Microscopic examination by Dr. John Homans showed the glandular tumors and the morbid growth at the base of the brain to be composed of small spherical and ovoid cells containing distinct nuclei and somewhat granular, together with more or less nucleated fusiform cells, but there were very many less of these latter in the glandular tumors than in the other morbid growth.

At the request of Prof. J. B. S. Jackson, I sent the specimen obtained from the base of the brain to Dr. Robert T. Edes, of Hingham, for minute dissection. The following is his description:

"The morbid growth seemed to be connected with the basilar portions of sphenoid and occipital bones, involving also the petrous portion of the temporal bones to a slight extent—the right the larger. Anteriorly I could not say very well what bones were involved, except that I recognized the clinoid processes anterior and posterior. The dura mater was spread over the upper surface and presented foramina for the passage of nerves; of these the second (optic) on the left side rested in a notch on the anterior portion of the tumor, and was apparently healthy. On the right side the notch was deeper and the distal extremity of the piece remaining with the specimen

was softened, and of a yellowish hue. Microscopically it presented many fat-granules, although a considerable portion of normal substance remained. The right nerve of the third pair was more deeply buried, and was adherent to the surrounding substance—was thickened and reddish. At the enlarged portion it presented a considerable proportion of fibrous tissue. At the point where it divided into its two branches to be distributed to the muscles of the eye, one branch contained much fibrous tissue, and few, if any, nerve tubes. Some parallel fibres were seen which were probably nerve fibres deprived of the medullary substance, since they did not present the usual dark bordered appearance. The other branch showed a very well marked condition of fatty degeneration, nearly all the fibres being dark and granular. The fourth nerve was found on neither side.

"The fifth was—on the right side—so deeply buried in, and closely united with the antero-lateral portion of the tumor that the branches a short distance beyond the Gasserian ganglion were very difficult to trace. The one which I did trace and which was probably the inferior maxillary division, was apparently healthy to the eye and to the microscope.

"The growth itself seemed to consist of fibrous tissue, with a great many small oval or elongated nuclei."

The fourth nerve on the right side had degenerated to a mere filament, and had probably been torn away in consequence of the prolonged handlings and examinations to which the specimen had been subjected previous to its being seen by Dr. Edes; on the left side the tumor was cut very near to the fourth nerve, which was probably likewise torn away.

A few points in this case are worthy of special notice.

The slow development of the disease and the still slower deterioration of the general health; the disease existing at least twenty months, and the patient being able to be about until a short time previous to her death.

The large relative increase of the white corpuscles of the blood taken in connection with the enlarged thymus and lymphatic glands and supra-renal capsules.

The loss of the physiological functions of some of the nerves involved in the morbid growth at the base of the skull, although the functions of the different nerves do not seem to have been impaired strictly in proportion to the apparent extent to which they were respectively involved by the dis-

ease. The right optic lost its function, as shown by the blindness of the eye of that side, the growth involving the nerve at some distance anterior to the optic commissure, which remained healthy. The substance of the right nerve of the third pair—*motores oculorum*—and also the right one of the fourth pair—*pathetici*—being involved, we should have expected loss of motion in the right eye, together with paralysis of its upper lid, and such was the case. Although the fifth nerve of the right side was deeply buried in the morbid tissues its functions were not much disturbed, which fact harmonizes perfectly with the result of the microscopic examination of its structure. The integumentary ulcerations in the right temporal region may have been due to degeneration of the auriculo-temporal branch, although, as previously stated, I could not detect any loss of sensation in any portion of the integuments covering the head and face. The functions of the other cranial nerves did not suffer impairment, with the exception of the sense of smell, which would of course be interfered with, in consequence of the existing obstruction of the nasal passages.

And lastly, the large relative increase of the white corpuscles of the blood, taken in connection with the enlarged thymus and lymphatic glands and supra-renal capsules, giving the case a decidedly leucocythæmic aspect when viewed independent of the growth at the base of the skull—as it was during life.

The morbid growth seems to have been identical with the *fibro-plastic* growth of Lebert and Paget, and the *sarcoma fusiforme* of some of the German pathologists.

What was the nature and cause of the disease? Was the morbid growth at the base of the skull the primary and main disease, and the glandular enlargements and increased number of white blood corpuscles mere sequelæ and concomitants? or were the whole series of pathological changes due to some abnormality of the blood-making organs or processes? or did the case present two different diseases, each independent of the other? The increased number of white corpuscles, the enlarged thymus gland and supra-renal capsules, and perhaps the enlarged lymphatics about the neck, all belong to leucocythæmia.

---

Drs. L. Damainville, W. H. B. Post, C. F. Roberts, and Albert Strang have received appointments as Sanitary Inspectors for the Board of Health in New York.

DISEASE OF THE SUPRA-RENAL CAPSULES,  
WITH A CASE.

Read before the Worcester North District Medical Society, Jan. 12th, 1869, by ALFRED HITCHCOCK, M.D., Fitchburg, Mass.

IN examining the anatomy of the supra-renal capsules, we find them largely endowed with bloodvessels and nerves; but without cavities or excretory ducts. Some anatomists state that no other organ of the body is so richly endowed with nerves. The physiology of these bodies is entirely conjectural. Dr. Wharton, in the last century, called them "nerve ganglions," and assumed a connection between them and the spinal cord and sympathetic nerve. Kölliker, a late German pathologist, thinks there is a connection between these organs and the brain, and the anatomical resemblance between these bodies and the solar plexus, as revealed by the microscope, is remarkable; the cell-formation is said to be very like nerve-cell, if not identical with it. Certainly their minute anatomical structure is very different from that of the thymus and thyroid glands, with which they are often associated. It has been observed by anatomists that in negroes and other dark races the size of these bodies is relatively greater than in the white races. This fact has been followed by the inference that these bodies were in some way associated with the genital organs, which are well known to be more largely developed in negroes than in the white races. Dr. Brown-Séquard has shown that injury of the spinal cord above the supra-renal capsules is followed by hypertrophy of these bodies; and that their removal from living animals is followed by an accumulation of pigment in the blood, and his hypothesis of their function is "to prevent the formation of pigment in the blood." These bodies are known to have been the seat of tubercle, of cancer and of cystic tumors; of apoplexia, degeneration and hypertrophy; and yet the diagnosis of disease of these bodies is hardly possible, except in that stage of disease which is now well known to be associated with a "bronzed skin." Dr. Addison,\* the senior physician of Guy's Hospital, London, after a long and laborious research, and after watching a large number of cases during life, and verifying the pathology after death, has established the fact that a peculiar degeneration and hypertrophy of the supra-renal capsules is associated with a peculiar variety of bronzed skin. His cases show, in their history,

great nervous and mental prostration, a flabbiness of the muscles, great breathlessness, epigastric pain or uneasiness, and nausea, increasing debility, and, generally, sudden death. Emaciation is usually not great; and sometimes, or very often, the disease exists with a large amount of adipose deposit in all parts of the body, although the patient is decidedly anæmic. In these cases the supra-renal capsules are usually enlarged, hardened, and of a yellowish color; quite often they cross the vertebrae and coalesce as one body. Minute dissection and the use of the microscope simply show negatively that the enlargement is neither tuberculous nor cancerous, but something resembling (to the eye) a fibro-plastic growth, presenting under the microscope amorphous granules in a net-work of delicate white tissue. The bronzing of the skin in these cases may be general or very limited, and usually begins on old cicatrices, or about the face, the nipples, or the genitals, or on the knuckles, the elbows, or the epigastrium. The skin at the points of discoloration appears unchanged in structure—the rich "bronzing" is all that is noticeable. In this respect the staining is unlike "*moth patches*," or "*ephelis hepatica*," or "*maculae hepaticae*," or the copper-colored eruptions of tertiary syphilis, or the straw-colored hue of anæmia. There is no desquamation, nor any kind of moist or dry exudation, and the bronzing cannot be *washed* or *rubbed* off. In Dr. Addison's cases the shade of coloring differed: in some it was of a mulatto hue, and in others like that of a quadroon; in some it was general, but in most it was marbled, selecting, as before stated, flexures of joints, cicatrices, and points near where the skin and mucous membranes coalesce. In some of the *marbled* cases the intervening skin appeared of a pearly whiteness by contrast, as though the pigment might be defective in some parts and deposited in excess in others. Dr. Addison found also that the peritoneum and pleura in these subjects exhibited the same bronzed discoloration in spots.

Disease of these bodies may be acute or chronic; and, according to Dr. Addison, the "bronzing" follows in the same order. Cases are reported which lasted from two months to seven years. In some, the disease has seemed to give a *truce* of a few months or years, ultimately returning and destroying the patient, and giving an opportunity to verify the pathology. In the summing up of this subject (with characteristic modesty), Dr. Addison says:—"My ex-

\* Dr. Addison died in 1860, aged 67.

perience, though necessarily limited, obliges me to consider the disease as *frequent*, and one which, when we shall have become familiarized with its symptoms and progress, will lead us to discover instances which, in the present state of knowledge, pass unheeded or undetected. I am satisfied that if a partial disease of the supra-renal capsules gives rise to a condition and symptoms too equivocal to authorize a confident diagnosis, a more extensive lesion produces a group of phenomena sufficiently well marked to make us not only suspect the source, but even confidently affirm that it depends on a disease of the capsules. When the pathological alteration of these organs is acute and rapid, I believe that, the anæmia, prostration and peculiar discoloration of the skin pursue a similar course. In every case, whether acute or chronic, *when the disease has included the whole of the two capsules, death has been the inevitable result.*"

It was my privilege to see Dr. Addison's cases of this disease in Guy's Hospital in 1851 and 1852, and to hear from his own lips the history of the cases and the results of some of his *post-mortem* examinations. In 1855 he published his monograph on the subject. In 1856, Dr. Hutchinson, of London, wrote a review of Dr. Addison's book, and analyzed his cases, and came to the following conclusions.

"1st, No single case has yet been recorded in which a well-marked bronzed condition of the skin existed and recovery ensued, nor in which, after death, the supra-renal capsules were proved to be healthy.

2d, "No single case has yet been recorded in which, after death, both supra-renal capsules were found disorganized by chronic disease, and in which the skin during life had not assumed the bronzed condition."

Since this was published cases have been reported which seemed to conflict with these statements, although in the main Dr. Addison's and Dr. Hutchinson's conclusions are sustained, so that we may now consider this disease about as well established as "Bright's disease"; or as "leucocythæmia," as established by Bennet and Virchow. It is a little remarkable that these three diseases have all been identified by men of the present generation, all belong to the *cachexiæ*, and are all about equally intolerant of remedies.

The researches of Dr. Addison and of all who have followed him in studying the pathology of the supra-renal capsules, lead to the conclusion that these bodies exercise an important, but unknown function; that

they possess an intimate and important connection with the organic system of nerves; that their morbid condition modifies the relative quantity of the pigment of the blood; that they are subject to all the usual results of inflammation in other tissues; that they are also subject to *cancer*, *tubercle*, atrophy and hypertrophy, as well as to a peculiar enlargement, induration and degeneration which is unique and unclassified; with all of which morbid conditions there is always associated more or less *bronzing of the skin*. Disease of these bodies may be independent of any other local affection, or may be associated with disease in other organs; but in either case there is anæmia, and all those depressing symptoms which attend exhausted vitality. When both organs are involved so as to suppress their function, whatever that function may be, death is the result. It is quite probable that when only one capsule is involved the patient may recover and live for an indefinite time. Of remedies we know none except such as are usually given in cases of extreme debility from anæmia arising from other causes. The usual routine of tonics and good diet comprises about all that can be said on this subject.

The true diagnosis in these cases can seldom if ever be made out till the disease is far advanced, and even then we know of no remedy that promises relief except that class of agents and influences which restores vital power and builds up the nutrition and tone of the system.

In my own practice I have had but one well marked case of this disease, which I will here relate, and exhibit the morbid specimens for your examination.

Mrs. W., aged 25, of a sanguine and nervous temperament, with dark hair and eyes, and a mixture of the brunette and florid in her complexion. Was confined with her first child April 18th, 1866. For two or three years previous she had suffered a good deal from dyspepsia and chronic diarrhœa. During her pregnancy she was very well, became quite fleshy and had a very roddy countenance. For the last three weeks she had a dry cough, and sometimes had faintness and dyspnoea. Her accouchement was attended with no unusual symptoms; the child was healthy, and every circumstance in her case for several days gave promise of favorable recovery. The secretion of milk was established, and the appetite and digestion seemed to resume their natural condition. She, however, continued weak, would easily faint, had a slight, dry, hacking cough, with some dyspnoea, and grew

very sensitive to all causes of physical or mental emotion. At the end of three weeks she rode out two or three times a short distance, but was evidently too weak for the effort. The last time she rode out she unfortunately encountered the shocking sight of a horse impaled on a picket fence, completely eviscerated, and dying by the roadside. This produced a very severe shock. She immediately became alarmingly faint, was carried home, took to her bed and was never again able to be raised fully up in her bed without fainting. From this time the milk wholly disappeared. The appetite diminished and became capricious. The pulse, which had been a little quicker than natural since her confinement, now rose to 100 and 120, and was very soft and feeble. There was almost constant nausea, with epigastric pain or uneasiness; sometimes pretty severe pain in the right lumbar region, and occasionally fugitive pains about the chest. She was almost constantly troubled with breathlessness, as if wanting more air without the strength to inflate the lungs. There were no physical signs of thoracic disease; there was no diarrhoea, no sore mouth, no sweating, no morbid discharge from the kidneys or bowels, no chills, no fever, save, perhaps, a flush over the malar bones for the last few days of life, no delirium till in articulo mortis.

About two weeks before death the skin assumed a dark, dingy look, more manifest in spots; the appearance being dirty, as though soap and water would remove it.

Dr. Woodward, of Worcester, who with Dr. Colony saw the case with me, first suggested the possibility of supra-renal disease in this case. These spots very soon became bronzed of a very deep color, leaving no doubt in our minds of the true nature of the disease.

The bronzing was chiefly manifested on the breasts, at epigastrium, around the navel, and lower part of abdomen, at the knuckles and knees, and wherever there was a cicatrix, or any irritation or abrasion of the skin had existed. All the symptoms of debility, with the bronzing of the skin, continued to increase till death, which took place June 6th, about seven weeks after confinement. A *post-mortem* examination was made the following day, Drs. Colony, Miller and Rice being present.

There was a good deal of adipose tissue on the body, and the bronzed spots were even more manifest than before death. There was a very slight adhesion of the apex of the left lung, and in the vicinity were a few small tubercles, and one cavity about the

size of a pea. The right lung had a few very small tubercles at its apex. The bronchial tubes contained a good deal of frothy mucus or serum, which was evidently one of the last changes before death. The heart was soft and flabby, as were all the muscular tissues of the body.

The stomach and intestines showed no disease, though they were very thin and pale. The liver appeared natural, except that there was a studding over the surface of minute pale white spots, as though minute drops of milk were flattened underneath the peritoneal surface.

The kidneys, pancreas, mesenteric glands and genital organs were perfectly healthy. The supra-renal capsules were greatly enlarged, dense and yellow, and coalesced into one mass across the spine. When first removed they were five and a half inches long and of a width varying from one to two inches, semi-lobulated, and with curvilinear margins; the average thickness was about half an inch. They were yellow, dense in structure, and had a feel and an appearance under the knife, intermediate between scirrhus and hard tubercle; and under the microscope nothing was revealed to identify them with either.

#### CEREBRAL AMAUROSIS.

By Dr. G. MEYER, K.K. Kreisphysicus in Steyer.

[Translated for the Journal by R. JOY JEFFRIES, A.M., M.D., from the Vienna Weekly Medical Journal.]

(Continued from page 76.)

THAT *apoplectic effusions* may sometimes cause amaurosis is readily conceivable. I speak only of cases where this symptom was of special import. Of seven cases (reported by Dunn, Risdon and Bennett, Kanka, Henkel, Weber, Beck and Romberg), the extravasation was twice in the corpus striatum, twice in the hemispheres, once in the optic thalami, once in the crus cerebri, and once in the cerebellum. In the last case, the anterior part of the right cerebellum was softened to a pulp, the cerebral vessels atheromatous, especially the arteria vertebralis; the optic nerves soft and atrophic. There was marked sexual excitement in this case, weakness and stiffness in the left foot, and severe pain in the back of the head. In Risdon and Bennet's case, as also in Kanka's, there was organic disease of the heart and an atheromatous condition of the cerebral arteries; in two other cases, this latter. In one case the effusion was in the middle of the left corpus striatum, and paralysis of all the voluntary muscles of the

right half of the body. In Kanka's case there was blindness of the right eye, reduced vision in the left, palpitation, headache, with great weakness. There was found insufficiency of valves of the aorta from ossification, dilatation of left ventricle, the right internal carotid dilated and atheromatous, as also the ophthalmic, the optic nerve up to the chiasma altered to a thin string, the left one apparently unchanged. In the left anterior cerebral lobe, near the corpus striatum, a not very old apoplectic effusion the size of a walnut. In this case it seems that the apoplectic effusion was not so connected with the ocular trouble which had previously commenced as with the disease of the ophthalmic artery and heart. In Romberg's case there was an old extravasation in the right and a fresh one in the left hemisphere. Symptoms of muscæ volitantes and phantasm preceded the blindness. Paralysis, of course, accompanies these cases.

*Hardening of the brain*, with troubled vision, is reported by Horoship (Abercrombie, l. c. 251), by Spanton (*Med. Times*, May, 1863), and by Romberg (*Lehrb. d. Nervenkrankheiten*, l. p. 193). The first case was that of a boy who had been struck on the head with a ruler; a tumor formed and discharged pus for six years, and then healed, upon which dimness of vision and epilepsy occurred; section showed the pia mater inflamed at the point of injury, and the whole middle cerebral lobe hardened. In Spanton's case the left crus cerebri and the anterior part of the commissure was hard and fibrous, the left oculomotorius thinner and bluish; there was corresponding paralysis of the left oculomotorius, and paralysis of motion and sensation of the right half of the body and face; diminished accommodation *left*, is all reported. In Romberg's case there was hardening of the inner edge of both posterior lobes of the cerebrum and of the cerebellum, besides four ounces of yellowish serous fluid filling the dilated left ventricle. The most marked symptoms here were headache, dizziness, vomiting, squinting of the right eye, dilatation of the pupils, convulsions and sepor.

Cases are not so very rare in which *aneurism of the cerebral arteries* caused amblyopia and amaurosis. Of eight cases (reported by Abercrombie, Hare, Barth, Middlemore, Ogle, Spurgin, Flandin, Delpech), the aneurism was three times in the left communicans post., twice in the internal carotid, twice in the art. corp. callosi, once in the art. cerebelli anter. sin. In two cases (art. corp. call. et art. commun.

post.) there was no disturbance of vision. In these cases, besides headache and dizziness, there was paralysis of some of the ocular muscles and apoplexy noticed. In two cases the disturbance of vision was only on one side.

According to Lebert's investigations, aneurisms of the cerebri media are much more frequent than of the other carotid branches, and he points out that dilatation of the carotis int. presses the optic, of the communic. post. the oculomotorius, of the communic. ant. the chiasma; therefore for the carotid system troubles of vision and motions of the eye are of importance, and in aneurism of the carotid itself progressive amaurosis may appear upon one or both sides. A long latency precedes the marked symptoms. At first, general signs of organic cerebral disease, then pressure on individual nerves, troubles of the intelligence; later, paralyses and apoplectic attacks. The course is at first quite slow, but paralysis may suddenly occur.

Of diseases of the spinal cord in which amaurosis was a marked symptom, I found eight cases reported, by Teschenmacher, Abercrombie, Melicher, Steinthal, Chariot and Vulpian, Kanka, Romberg, and one case from the Vienna hospital. Among these, there was once softening of the medulla oblongata, induration of the same once, induration of the cervical portion once, induration of the anterior and posterior roots once, atrophy of the cord once, and breaking down of the connective tissue of the posterior roots once. In the majority of cases vision faded gradually, dimness preceding; headache only once; the other senses, hearing and smell, were each once affected; speech in two; swallowing troubled in one case; the special peculiar symptoms of spinal disease occurred, however, in all these cases—troubles of motion and sensation, feeling of constriction, trembling, &c. In Kanka's case, the amblyopia was complicated by tetanus. An apprentice, æt. 20, took cold whilst convalescent from typhoid fever, and severe pains in the limbs and temporary immobility appeared; there remained a gradually increasing dimness of vision, which went on to total blindness; the pupils moderately dilated, and repeated attacks of muscular stiffness and tetanic cramps. The spinal column was tender on pressure over the upper four dorsal vertebræ. Death occurred some two months after his reception, during such an attack. The spinal cord was found softer than common; the meninges somewhat infiltrated with serum.

Cases remain to be spoken of in which original disease of the cranial bones was the cause of amaurosis. In six such cases (reported by Abercrombie, Wepfer, Lyell and the Report of the Vienna Hospital, 1851-52), the disease was twice in the petrous portion of the temporal bone, twice in the left parietal bone, and twice also in the frontal and sphenoid bone. In one case, a medullary cancer, springing from the frontal bone and base of cranium, compressed the right corpus striatum; there was blindness on left, exophthalmus on the right, and paralysis of upper and lower extremities on left side. In another case (a fistulous opening of the left parietal bone into the cerebral hemisphere), there was paralysis of the extremities right, impairment of memory and slow articulation. In Lyell's case, a tumor of two ounces' weight lay in the left fossa orbit. of the parietal bone, and had affected the sphenoid where the foramen op. and lacrum pass through it, as also the nerves and vessels; a portion of the tumor surrounded the right optic. In this case, after a blow on the back of the nose, there appeared pain and deafness; later, an extended neuralgia of the trigeminus; and finally, after two years, increasing blindness, with paralysis of the motor nerves of the eyes. In those cases where the sphenoid bone was the seat of the disease, hearing was affected, as we should suppose. In two of six such cases there were epileptic attacks.

We can by no means determine from these briefly related cases, how often in these diseases the amaurosis was caused by them; for this a very much more extended statistical observation of cerebral affections would be necessary. We may, however, conclude that organic disease, especially cerebral tumors, and of these those in the hemispheres and hypophysis, very often produce amaurotic blindness. Blindness is always present where tumors, extravasations and exudations directly affect the optic or chiasma. According to Wunderlich, loss of vision may occur with the most manifold troubles; he, however, particularly mentions disease of the corpora quadrigemina, cerebellum, walls of the lateral ventricles, the middle and posterior lobes and the base of the brain. According to Lebert, there was trouble of vision in two fifths of the cases of cerebral tumors; and in 101 cases, 20—i. e. 20 per cent.—with total blindness. Whether blindness in these cases was on one or both sides, is seldom determined from the local disease. Morbid products at the base of

the cranium, as also at the base of the brain, generally cause binocular amaurosis; so, too, with affections of the hypophysis. Graefe says (*Archiv. für Ophth.*, 7, 2, p. 67):—"Unilateral disease of the hemispheres, whether apoplexy, encephalitis or tumors, causes, if the visual centre is affected, only hemiopic trouble in one or both eyes; never, however, complete blindness of the same or opposite eye." But cases of bilateral amaurosis, even with unilateral cerebral disease, are more frequent than unilateral blindness; this, in the majority of cases, is explained partly by the pressure on the chiasma, partly by the morbid products, even when unilateral, pressing on the other half of the brain, or causing interference of circulation there. These latter often produce amblyopia, as we know that inflammation of the optic nerve and adjacent parts of the retina are caused by pressure of morbid tumors on the sinus cavernosus. The cases of the above where unilateral blindness alone existed are as follows:—

1. Pus in the left orbit and cranium,	Blindness, left.
2. Aneurism left art. communic. pressing on left optic,	" left.
3. Abscess left cerebral lobe,	" left.
4. Apoplectic deposit in right anterior cerebral lobe,	" right.
5. Softening of left corpus striatum,	" left.
6. Softening of left corpus striatum and thalamus opticus,	" left.
7. Hydatids, left hemisphere,	" right.
8. Three cases, tubercle in left half of pons,	" left.
9. Tumor in pons, reaching to right crus cerebri,	" right.
10. Medullary cancer in right crus cerebri and corpus striatum,	" left.
11. Cancer, left cerebellum,	" left.
12. Tumor, left thal. opt. and pons,	" left.
13. Hydatids, left opt. thal. (Romberg),	" left.
14. Tubercle in right corp. oliv., right half of chiasma and commencement of right optic nerve, and its optic tract infiltrated with tubercle,	" left.

According to Serres, anomalies in the optic thalami, and, according to Breschet, troubles of the anterior cerebral lobes, do not necessarily produce blindness.

Before I pass to the discussion of the symptoms accompanying these various organic cerebral affections, in order to connect their appearance with the organic disease and establish the diagnostic value, I would further add that among the cerebral tumors are included the hydatids and tubercle. Of the first, thirteen are noted. Four at the base of the brain, three in the hemispheres, two in the left lateral ventricles, two in the hypophysis, and one in the left optic thalamus. In twelve cases the tumor was recorded tuberculous; of these seven were in the hemispheres, three in the pons, one in the cerebellum and one in the hypo-

physis. As respects age, both hydatids and tubercle occurred much more frequently in young individuals, whilst the age in the cerebral tumors (mostly sarcoma and cancer) was very varying.

As respects the symptoms we must remember, that many of the diseases mentioned, especially cerebral tumors, may remain quite latent an indefinite time, and that this is particularly the case during their commencing development, so that the symptoms only become more marked as the growth of the tumor causes pressure upon the various parts of the brain, or upon certain nerves and nerve districts, or finally the circulation is interfered with. It is to be further noticed that towards the end of the complaint certain symptoms appear as so-called terminal phenomena in the most various cerebral diseases, and in the most varied seat of the same; amongst these are especially noticed sopor and comatose attacks, loss of sensation in the higher organs of sense and over the whole body, convulsive symptoms, general paralysis and general torpor, with emaciation. Death from apoplexy, coma and paralysis of the brain generally close the scene.

*Pain in the head* was present in nearly all the cases recorded, most constant with disorganization of the hypophysis, the hemispheres and the pons, also with softening and abscess. Pain in the head is relatively rare with hardening of the brain, and diseases of the spinal cord. In affections of the cerebellum it is present, and felt more in the back of the head. (According to Andral's observations there was pain in 26 out of 36 cases of cerebral tumors.) The seat of the pain does not always correspond to the seat of the disease. By reduction of the sensibility, pain in organic cerebral disease often intermits, so also often the pain in the head ceases entirely when total blindness has occurred. Pain in the head is always present in diseases of the pericranium and cranial bones.

*Dizziness* is a very inconstant symptom, especially, however, noticed with tumors of the hemispheres, in some cases of disease of the hypophysis and in aneurisms of the cerebral arteries.

*Troubles of consciousness* (sudden or oft recurring unconsciousness) are most frequent with diseases (tumors) of the hemispheres and softening of the brain. Attacks of sopor and coma are reported especially in cases of disease of the hypophysis, exudations at the base of the brain, formation of pus and cerebral abscesses.

*Troubles of the mental faculties* were no-

ticed in several cases of disease of the hypophysis (5 times in 22 cases) and in apoplectic effusions (3 times in 7 cases).

*Sopor* was rarely reported as a symptom (only twice in tumors of the hemispheres, and in one case of tumor of the hypophysis, one, hydatids in the ventricles, and one with softening). *Sleeplessness* in two cases of cerebral tumor.

*Apoplectic attacks* occurred, besides the seven recorded cases of apoplectic effusions, three times in tumor of the hemispheres, once in tumor of the pons, once in multiple tumors, once in exudation in the ventricles, once in aneurism, and once in disease of the bones.

*Epileptic attacks* were recorded in tumors of the hemispheres four times, of the base of the brain twice, in multiple once; in disease of the bones twice, induration of middle lobe (previous injury) once, softening of the hemispheres once, abscesses of anterior lobes twice, aneurism art. cerebelli once.

*Vomiting*, so often observed in cerebral disease, was most constant in exudative processes on the surface and at the base of the brain (7 times in 8 cases), in tumors of the hypophysis (5 times in 22 cases), and of the hemispheres 4 times in 22 cases.

*Hyperæsthesia* of the nerves of sensation was seldom mentioned as a symptom (3 times in disease of the hypophysis); increase of sensibility occurs most frequently in the sense of sight and hearing.

[*Hyperæsthesia* of the optic (photopsia, phantasm) was particularly marked in two cases of Romberg's, where the optic thalami were affected. In one case (reddish-gray pulpy softening of left optic thalami, and cavity in posterior lobes of right hemispheres filled with olive-colored fluid), there was also dizziness and unconsciousness, weakness and then paralysis of the left arm, and apoplectic fits, after the second of which death occurred. A second case also ended fatally with apoplexy, in which there was headache and loss of vision, unconsciousness and impaired motion, and loss of speech. The left lateral ventricle was filled with a mass of bladder-like hydatids, and both optic thalami with the whole anterior cerebral lobe changed to a pulpy mass. Photophobia was also reported in one of Romberg's cases, in which there was softening of the septum lucidum, fornx, and the walls of the lateral ventricles.]

That in cerebral diseases other senses besides the visual should be affected, is, of course, natural; it depends upon the locality and extent of the affection. First of all this applies to hearing, and in the above

mentioned cases this sense was expressly noted as impaired or entirely destroyed in 17. In the majority there was disease of the bones (pars petrosa), also in tumors of the hemispheres, the pons and in multiple tumors. The participation of the other senses (smell and taste) occurred 10 times, 4 times in tumors of the hemispheres, twice in tumors of the pons.

Fardel (*Bull. de la Soc. Ant.*, Aout. 1836) observed a case of encephaloid of the right posterior cerebral lobe, a similar mass on the crista galli, in meatus auditorius and the cavity. The patient had pain in head and nasal hemorrhage, became suddenly blind and deaf, first left, then right.

*Impaired speech* is a symptom which has lately been carefully studied in reference to the locality of the cerebral disease. Amongst the whole number of cases it was noticed 23 times; in 5 cases of disease of the pons and crus cerebri, in 4 tumors of the hemispheres, in 3 of disease of spinal cord, once each in disease of ventricle and softening of the brain, finally once each in multiple tumors, disease of the hypophysis, hardening of the brain (in pons and crus), abscess, apoplectic effusion (corpora striata), aneurism, and disease of the bones.

In most of the cases of impaired speech, where *post mortem* was made, there was softening of the brain, preceded by embolus and thrombus; also neoplasms (tubercle) in the several lobes. As a rule the *left* half of the brain was affected. Most frequently the softening affected the frontal lobes at the base, generally called by the Germans the first basal turn. Besides, in several cases of aphasia, there was softening of the corpus striatum, the lobus occipitalis, thrombus or embolus of the corresponding art. foss. Sylvii et art. cerebralis media, disease of the olivary (Schröder van der Kolk), and finally disease of the cerebellum. Romberg mentions 5 cases where difficulty of articulation existed, and softening of the corpus striatum was found.

According to Dr. Benedikt's observations the cerebral hemispheres seem to be bearers of the ideas of speech and writing, the frontal lobes the associating organ of the motions necessary for producing written and spoken thought, the corpus striatum the motor centre of the associated impulses of the coördinated movements from the cerebro-spinal axis further down. The cerebellum and perhaps also the olivary, may be the coördinative centre for speech. Spoken and written thought has, therefore, in the brain no one single central seat; trouble with speech without paralysis of the tongue

in disease of the pons Varolii and crus cerebri indicates only disturbed transmission. As unilateral disease may cause trouble of speech, it would seem that the cerebral activity requisite for speech needs at least the combined action of the symmetrical parts of both halves of the brain. In Spanton's case (*Med. Times and Gaz.*, May, 1863) the left crus cerebri was found smaller and transparent like, hard above and behind, the anterior left part of the pons hard (strewed with fat cells and nucleated cells), the left oculomotorius thinner, blueish. Paralysis of motion and sensation of the right half of the body and face, paralysis of the left oculomotorius, the accommodation on left side reduced, speech not plain.

Broca has said that diseases of the *left* half of the brain are much more often accompanied with loss of speech, than those of the right, whilst Dr. Jackson reports 40 cases of trouble of articulation with right-sided hemiplegia, and only one case in which this difficulty was associated with left-sided hemiplegia. Stewart reports a case in which disease of the right half of the brain (hemiplegia of left side) was *without* impaired articulation, and later disease of the left half of cerebrum with loss of articulation. In a case of Peters's (*Gaz. Hebd.* No. 17, 1863) a case of aphasia occurred with softening of the third turn of the *right* cerebral lobe and obliteration of the right art. fossæ Sylvii.

*Difficulty of swallowing* was observed in tumors of the pons three times, tumors of hemispheres and hypophysis twice each, and twice in disease of the spinal cord.

Hyperæsthesia of cutaneous nerves, formation and dull feeling in the limbs (often precursors of paralysis), were most frequent in tumors of the pons, disease of the hemispheres and spinal cord. This symptom is seldom otherwise recorded.

*Convulsions* were pretty often noted in these recorded cases. They were most constant in pus formation and cerebral abscess (5 times), exudations of the meninges at the base (4 times), softening of the brain (4 times), and in tumors of the hemispheres (6 times in 22 cases). Otherwise this was not a very frequent occurring symptom. According to Romberg convulsions occur in tuberculous tumors most frequently preceding or accompanying paralysis, especially when they are in the cerebrum.

*Weakness and paralysis*, as troubled mobility, were much more frequent, and in respect to the diagnosis, particularly as to locality, of more importance. Such interrupted mobility was observed in the eyes

(as strabismus, luscitas, change of the pupil), and also in the limbs.

*Troubled mobility of the eyes* was expressed by strabismus, diverging squint when the oculomotorius, and converging when the abducens nerve was implicated. Such troubles were most frequent in affections of the pons and neighboring parts of the brain (6 times in 10 cases). Such ocular paralysis, especially from interrupted conduction through the oculomotorius, occurred also with tumors in the hemispheres and multiple tumors, exudations at the base, softening and abscesses in the brain, aneurisms and apoplectic effusion. Central causes affect the oculomotorius, especially the branches to the rect. inter. musc. and super., much more frequently than the nerv. abducens. Ocular paralysis is most frequently on the same side as the paralysis of the superior extremity. In some cases the *post mortem* perfectly explained the symptoms. In a case of Dittrich (*Prager Vierteljahrsschrift*, 1845, B. IV.) there was a tuberculous mass in the under surface of the pons Varolii, in which the left abducens was bedded, the left vagus atrophic, and firmly attached to the neighborhood of the jugular opening, the upper part of the nerv. access. Willis thickened thrice its size, infiltrated; tubercle in the right corp. oliv. pressing the root of the hypoglossus and facialis; the left half of the chiasma, the right nerv. opt. and optic tract infiltrated; both optic thalami and corpora striata soft and spongy. The patient's voice was rough, afterwards lost, difficulty of swallowing; weakness, numbness and formication of the left hand, *amblyopia left*, luscitas of left eye with diplopia. In one case of Beck's (*Amnon's Zeitschrift f. Chir. und Augenh.* IV. 3 et 4) the hypophysis was hardened the size of a nut, the nerv. oculomotorius and abducens on the left side pressed outwards by it, nerv. optic unharmed, brain and spinal cord softened as far as first dorsal vertebra. There was convergent squint of left eye, motion of the pupil perfect, binocular diplopia, blindness occurring suddenly but lasting only a few minutes, later mental trouble, sopor and death. In amblyopia with tabies there is frequently ocular paralysis.

[Convulsive oscillation of both globes, with general convulsions and loss of vision, was marked in a child, where all the cerebral ventricles were distended twice their size and filled with a reddish serous fluid. A plastic exudation covered the chiasma at the base. The nerv. oculomotorii were bedded in a brawny mass, which held them fast.]

*Dilatation of the pupil* accompanied in the majority of the cases any continued amblyopia or amaurosis. This symptom means generally want of reflex irritation of the oculomotorius from lack of sensibility to light. When on the other hand the oculomotorius is directly affected by organic cerebral disease, dilatation of the pupil depends on paralysis of this nerve. Alterations of the pupil are especially to be regarded in paralysis and amaurosis from caries of the vertebrae or other spinal diseases. The dilator nerves of the pupil come from the cord near the sixth cervical to the third dorsal vertebra, and pass to the sympathetic through the rami communicantes; the central seats of the iris fibres are the upper and lower cilio-spinal region (from the middle of the rhomboid depression to the second cervical nerve, and from third dorsal to sixth cervical nerve). Any disease, therefore, affecting these parts will be accompanied with alterations of the pupil. These often are simple dilatation of one, whilst the other pupil remains of normal size, as was known in some cases of caries or distortion of the last cervical vertebrae (Rosenthal, *Wien. Med. Presse*, 1865). In a case of Schuchard's (*Deutsche Klinik*, 1864), where during life there was alternate dilatation and contraction of one, then of the other pupil, *post mortem* showed tubercle in the body of the lowest cervical vertebra, displacement from the fourth to sixth cervical and from seventh to eighth dorsal vertebrae; in the corresponding part of the cord there was degeneration of the nerve tubes, from nucleated cells and fatty degeneration of the vessels. In tabes dorsalis, where the hardening comes high up in the cervical portion of the cord, we have the pupil affected, generally dilatation of one. This may be due to a spasmodic condition of the dilator caused by inflammatory irritation or the commencing hardening. If, however, there is paralysis of the dilator, then we shall have contraction of the pupil, the same as we generally observe in spinal amaurosis. Unilateral dilatation occurs also with many cerebral diseases, especially tumors, with hydrocephalus, cerebral softening, and as an important symptom with so-called general paralysis of the brain.

[To be continued.]

IN 1735 occurred the great epidemic known as the "throat-distemper," which has been supposed not unlike our diphtheria, and from this time dates the extensive use of mercurials, which were said to have been specially useful in its treatment.

## Hospital Reports.

### MASSACHUSETTS CHARITABLE EYE AND EAR INFIRMARY.

Some Cases in the Service of Dr. B. JOY JEFFRIES.

*Separation of the Retina.*—A laborer, æt. 22, awoke in the morning with sudden blindness of the right eye. Has had no pain or previous trouble. The ophthalmoscope showed a large retinal detachment upwards and outwards, extending over to the optic papilla. The papilla could be seen with its bloodvessels. The other eye is myopic  $\frac{1}{2}$ , and amblyopic to the extent of only counting fingers at 20 feet. The ophthalmoscope showed in it staphyloma posticum, and a large and irregular "crescent" two thirds round the nerve. There was, therefore, no doubt that the myopia depended on staphyloma, and that this in the right eye had been the exciting cause of the detachment of the retina.

*Separation of the Retina.*—A female domestic, æt. 24, without previous pain or other cause, has become suddenly blind in right eye. The ophthalmoscope showed detachment of the retina, and in the other eye a "myopic crescent" around optic papilla, vascular injection, and scattered pigment, pointing towards choroiditis as the cause of the retinal separation.

*Piece of Iron in the Sclerotic.*—A mechanic, æt. 44, has, from a chip from a chisel, a foreign body in the conjunctiva, between the inner canthus and edge of the cornea. On attempting to remove this with the forceps, it was found too firmly imbedded, and the conjunctiva was slit up, and a thread-like piece of iron, one fourth of an inch in length, was pulled out of the sclerotic. Although this was within the ciliary region, no trouble followed, and the wound in the sclerotic healed at once. No more pain or irritation was produced than would have been by any foreign body on the conjunctiva removed as soon as this was.

*Amblyopia Potorum?*—A drinking man, æt. 46, has a central scotoma as a grayish-blue spot or blur, some two or three inches in diameter at one foot distance. The ophthalmoscope revealed nothing to explain it. Cathartic pills of blue mass and leeches to the temples relieved the head symptoms.

*Peculiar Cystic Tumor of the Conjunctiva.*—A boy, æt. 6, had, some twenty months previously, in Feb., a stick thrust into the left eye. The mother states that a piece of the wood not larger than the

head of a pin remained in the eye till July, and was then removed. There is now a tumor on the inner and upper side of the cornea, encroaching a little on the latter. It lies round the cornea as it were, is quite prominent, seemingly translucent, and looks like conjunctiva filled with serum. Although it was apparently based on the sclerotic, it evidently was not a staphyloma of the sclerotic coat. With the idea that a foreign body might be within it somewhere, it was slit up, and the fluid, of a serous character, allowed to pass off. The bottom of it was found to be the sclerotic itself, and careful dissection revealed no foreign body. The patient was not again seen, as there was no other trouble with the eye. The chances are that it will again fill, unless some slight inflammatory action closes it from the bottom. No artificial irritation was attempted, as the sclerotic itself was laid bare. A similar case has occurred since.

*Lens dislocated by a Blow.*—A farmer, æt. 18, received, some two months since, a blow from a club over the left eye, and there is now a scar an inch long on the outer and upper border of the upper lid. There is a little exophthalmos. A sclerotic staphyloma up and in. The pupil dilated, the iris tremulous. The lens was seen by the ophthalmoscope to be dislocated up and back. Vision reduced to  $\frac{1}{50}$ . This unfortunate patient was a fortnight at home with the injured eye badly inflamed, during which time he, by advice, made use locally of *poppy leaves, raspberry leaves, acetate of lead, brandy, and arnica*. How much these tended to prevent the firm union of the ruptured sclerotic is hard to say. If the lens is pressing on the ciliary region, the eye will probably not long remain quiet as it now is.

*Swelling of the Lachrymal Gland?*—A little girl, aged 6, has what was supposed to be swelling of the lachrymal gland; the lid over it is tender and red, and a tumor where the gland should be. The eyelids were closed. From the general condition of the patient, cod-liver oil and quinine were ordered, under which the swelling disappeared too rapidly for anything like an abscess, &c.

*Swelling of the Lachrymal Gland.*—A little girl, æt. 4, has oedematous swelling of the right lid and serous infiltration of the outer part of the conjunctiva. In this oedematous swelling, the lachrymal gland could be felt *in situ*, as large as a filbert. A leech and warm-water lotions reduced the whole. About this case there was no doubt. The

previous one was not as clear at the time it was first observed. The last child had had eczema and a sty on the lower lid some six months before.

*Retinal Hæmorrhage.*—A man, æt. 45, complains that all the central field of vision has gone, and ophthalmoscopic examination reveals a retinal hæmorrhage covering the macula lutea and reaching to the optic papilla. Considerable albumen was found in the urine, and the hæmorrhage therefore attributed to renal disease, as was also shown by other symptoms. The case was, therefore, not treated at the Infirmary.

*Coloboma Iridis downwards in both Eyes.*—A little girl, æt. 7, has congenital coloboma iridis. The pupils are two thirds of an oval, fortunately downwards, and therefore not covered by the lids. The patient, although a request was made, was not brought again for ophthalmoscopic examination, to ascertain whether the choroid was also imperfect. The pupils were nearly symmetrical, and gave the child a peculiar look, exactly as if a very careful and successful double iridectomy had been done, as for congenital stationary nuclear cataract. In such cases there is generally an absence of the choroid, the width of the deficiency in the iris, towards and nearly up to the optic papilla. This the ophthalmoscope shows very perfectly; the drawing of a case is to be found in the *Klin. Monatsblätter f. Augenheilkunde*, vol. v., p. 65. These cases show the anatomical relation of the choroid and iris. The retinal vessels are generally found running over the space where the choroid is absent, although vision is here deficient—i. e., the field of vision is defective over a space corresponding to this. This little patient was too young to attempt to obtain any examination of the visual field.

## Bibliographical Notices.

*Atlas zur Pathologie der Zähne.* Bearbeitet von Weil. Prof. Dr. M. HEIDER und Prof. Dr. C. WEDL. Die Zeichnungen Sämmtlich nach der Natur aufgenommen von Dr. C. HEITZMANN.

*Atlas to the Pathology of the Teeth.* Arranged and explained by the late Prof. Dr. M. HEIDER and Prof. Dr. C. WEDL. The Drawings from Nature by Dr. C. HEITZMANN. Leipsic, London and New York.

WE have just received from Prof. Wedl, of Vienna, two parts of the atlas on dental Vol. III.—No. 9b

pathology, the forerunner, as we are informed by private letter, of an extensive text-book on the same subject by this distinguished histologist. The portions of the atlas already issued contain eight folio plates and eighty-one beautifully executed drawings on stone of preparations from the pathological collections of the late Prof. Heider. Two more parts will complete the series and form a work especially valuable in America, the paradise of dentists and the home of the most enlightened dental science.

We are told by one of the professors in the Dental School that no satisfactory work on the subject at present exists, and, with the exception of here and there a chapter in general works on the teeth, dental pathology is sadly neglected. No persons could better fill this gap which is felt to exist in medical, and particularly dental education, than the Professors above named. The one, dying after a long and successful term as an instructor in the Vienna University, left a collection of preparations in dental pathology of great value, and the materials of this work; the other has worked through a long life as a faithful student of nature, and has added many valuable monograms to science. The latter has now carefully arranged the atlas, and is busy on the text of the work.

The atlas should find a place in the library of every pathologist, as well as dentist and dental student.

F. H. B.

## Medical and Surgical Journal.

BOSTON: THURSDAY, APRIL 1, 1869.

### THE CHILDREN'S HOSPITAL.

IN announcing the incorporation and establishment of the Children's Hospital, we are permitted by the Secretary to make extracts from a statement which was drawn up by four physicians of Boston, in reference to the accomplishment of the plan; we are thus enabled to explain to the profession the initiatory steps already taken for the foundation of so desirable a charity.

With the exception of a hospital which was started by a gentleman some years ago, which continued a year or two and was then abandoned, Boston has never had a hospital exclusively for the care of sick children. Nevertheless, those who are

called to practise among the poorer classes know full well the sad mortality of children in these classes, the impossibility of obtaining the proper care, cleanliness, and hygienic surroundings, the reluctance and comparative inability of our existing institutions to receive children into their wards. Many of us have been witness to the good results which have been accomplished in the hospitals of the Old World for the exclusive care of children, and have longed for a similar institution in our own city. With these considerations and some others in mind, we gladly welcome the establishment of a new and noble charity.

The actual need of such an institution can hardly fail to impress itself on the mind of every candid practitioner. The Dispensary physician is constantly and painfully made aware how his directions are neglected, his practice rendered void and his patients killed by the carelessness, the ignorance and the stupidity of their families. We may fairly assume, moreover, that for one child whom disease kills, there are many whom it, more or less, cripples for life, and who, from the cradle to the grave, never enjoy the full possession of health and strength. We cannot hope to take care of *all* the children in the city; but we can look for the amelioration, to a greater or less degree, of some of the evils of sickness; we can hope for some lives saved and some sad hours made easy. We are, therefore, glad to know that many of the most influential men of our community have become deeply interested in this work, and are heartily coöperating for its successful establishment.

We let the medical projectors of the plan tell their story in their own words:—

“The plan which it has been proposed to carry out in this charity has a threefold object; viz.:—

1. The medical and surgical treatment of the diseases of children.
2. The attainment and diffusion of knowledge regarding the diseases of children.
3. The training of young women in the duties of nurses.

We wish to accomplish this threefold object by the formation of a corporation, which shall authorize the organization of a

suitable hospital, and place it under the care of a board of managers, chosen from their own number.

Is the charity needed? We answer that, in our daily professional walks, we see, at the public hospitals, the central office of the dispensary, and in practice among the poor and the working people, that the children are constantly exposed to influences which invite disease in its saddest forms; and the attendant is expected to do that for these classes, which he frequently finds it difficult to accomplish for those in the happiest circumstances. Medical statisticians well know the sad fatality of children in our community; medical practitioners are painfully aware that the hygienic influences which surround the children of the poorer classes are of the worst description. We desire to afford these sufferers, for darkness, the sunshine from heaven; for filth and disorder, cleanliness and system; for the rough word or neglect—maychance a blow or threat—gentleness, kindly attention, encouragement; for mephitic odors, sweetness and purity in their truest sense.

Again, it is constantly falling under our observation, that, among those of this class who are doing their best to live respectably; whose dwellings, although humble, are neat and orderly; who have a laudable desire to rise out of their present condition, and who have every good intention in serving their disabled children—many are unable to carry out the proper treatment. It is impossible to leave stated tasks to give the needed medicine at the right time, or to apply the proper dressing. It is hard for one to watch all night, after bodily toil all day; nature will overpower the senses, however strong the affections.

Among the thousand ills to which these children are subject, there are what we know as acute wasting diseases, such as scarlet fever, bronchitis, fevers; hip disease, abscesses, &c. If these diseases do not entirely exhaust nature and cause death, they very frequently leave the patients with enfeebled frames, and many a little ache and ail which future years only serve to strengthen, not efface. Many, very many children sink into early graves, and greatly swell the bills of mortality of those

who die before reaching adult life. We not only desire to treat these cases, and such as these, successfully, but we also wish to give a tone to the general health of our patients, which may have an influence on their future life. It is in aid of these sufferers that your medical committee stand ready to exert themselves, only asking your sympathy and coöperation in their labors.

What means have we now in our city for the medical and surgical treatment of children? Children are considered undesirable patients in a hospital, and therefore no provision on an extended scale is made in our existing institutions. Although often received and kindly cared for in our present hospitals, it is undoubtedly the fact that the interests of our various institutions cannot allow them to receive many children as patients. Moreover, these little sick children are entirely out of place among sick adults. Adults can complain, if they are neglected; the little fellows cannot do so, or fear prevents them. Our well-ordered charities will not permit neglect or ill-treatment of any one; nevertheless the liability to neglect exists. The beds and general appliances and conveniences of an adult hospital are not fitted to children. Physicians and nurses for children should have a peculiar adaptedness for the management of their young charges. All these matters are well understood by yourselves, interested as you all are, or have been, in public charities.

We cannot help mentioning, aside from the medical welfare of the children, a fact which we have noticed in some of our exemplars, both in this country and Europe; namely, the powerful influence which they are exerting in another direction, by removing, even for a short period, some of the little rough shoots of society from scenes where every moral and mental tendency seems to be in the wrong direction—and *humanizing* them. 'A few weeks with us,' said a noble Christian woman—at the head of one of the New York institutions—to us a week or two ago, 'gives a different expression to their faces, and a different tone to their whole characters.' . . . .

Even in so short a time as one month, the expression of the face of the, at home,

perverse and ugly, becomes humanized by—let us say—the divine influence, surrounding them. God's blessing seems to be upon these places; we earnestly pray him to continue and sustain them.

We believe that, apart from the actual medical treatment of sick and injured children, there is a want in our community which has long been felt in our medical schools, though provided for in foreign cities; namely, an opportunity to study infantile disease. We quote from the experience of a well-known children's hospital in London in reference to children's diseases: 'These, every mother and every nurse knows, or ought to know, are so sudden, so fluctuating, and so mysterious in their nature, and often so fearfully rapid in their fatality that they furnish a distinct branch of medical science, the importance of which can hardly be sufficiently recognized. For people forget that on the health of the growing up generation hangs that of generations more; also, that it is not merely the alternative between life and death, but between wholesome, happy, enjoyable life, and the innumerable forms of death in life which an unhealthy or neglected childhood entails upon the innocent sufferers to the end of their days.'

Still farther, we wish, in connection with the hospital, to initiate a system, hitherto unknown in Boston, of instructing young women of the middle and lower classes in the duties of nurses, both for children and adults. . . . .

We have worked silently and carefully for more than a year in studying the wants of the community, and in perfecting the plans which we ask your coöperation in carrying out. These plans we have fully reported to yourselves, and shall gladly communicate whenever desired by proper persons. . . . .

It is sufficient to say, that, so soon as a corporation is formed, and a board of managers appointed, we shall be ready to point out to them how our plans can be carried into successful operation.

In conclusion, let us venture to hope that you will clearly see the need of an institution for sick children in our city, and the undoubted benefit to our community of

such a charity. We feel justified in saying that we believe it will become an honorable, as it will be a popular, charity; and, for the furtherance of our efforts, we again ask your sympathy and support."

ATTENTION is called to the advertisement headed "Infants' Hospital, Randall's Island, New York City."

On opening the *The Dental Cosmos* for March, we noticed that the leading article was by J. H. McQuillen, M.D., the Senior Editor; its subject, the "Action of Anæsthetics on the Blood Corpuscles." On reading it, we found it to contain a report of important original observations, and marked for extract the passages we give below. We also wrote immediately to Dr. McQuillen, soliciting the loan of the wood-cuts illustrating the letter press. Through his kindness in granting our request, we are enabled to furnish the extracts illustrated by the original delineations.

The results but briefly stated in our extracts were reached through a vast number of experiments.

"When under the prolonged influence of nitrous oxide referred to, one of the blood-vessels of this animal [a rabbit] was opened for the purpose of examining the blood corpuscles under the microscope, and ascertaining whether they had become disintegrated or any change had taken place in their form. On examination, no perceptible difference was observable, even after this lengthened exposure to the anæsthetic, when compared with the blood of another rabbit, which was not under its influence. This result induced me to examine into the statements made by Dr. Sansom, relative to the action of anæsthetics on the blood corpuscles, in his interesting and able work on chloroform.\*

"In drawing [his] conclusions, of an altered condition of the blood, from appearances presented by the blood *out of the body*, Dr. Sansom evidently leaves it to be inferred that somewhat if not exactly analogous results are produced on the corpuscles *in the body*, when human beings or animals are under the influence of anæsthetics by inhalation. After a patient, oft-repeated series

of experiments performed by me during the past three months, not only on blood out of the body, but also in cases in which human beings and animals have been placed under the influence of ether, chloroform, and nitrous oxide, and the blood drawn from them *prior to and after* the administration of these agents has been carefully *examined and compared*, the results obtained compel me to take very decided exceptions to such conclusions being justifiable in the premises.

"*First Series.*—The experiments were as follows:—In my examinations of the blood of man and animals, when ether and chloroform were brought in direct contact with it out of the body, under a fifth objective, the discharge of the nuclei and the disintegration of the corpuscle have invariably occurred, and in the frog leaving a result similar to that which is presented in the accompanying drawing (Fig. 1), from one of

FIG. 1.

Frog's blood placed upon the slide, and chloroform brought in direct contact with it.

my specimens, wherein it will be observed that the field is occupied by the nuclei, *débris* of disintegrated globuline and corpuscles, in which the change of form, size, and other characteristics are most striking.

"*Second Series.*—On placing, however, two glass slides containing frog's blood over watch-crystals, one holding chloroform and the other ether, and covering them with glass finger-bowls for half an hour, thus exposing one to an atmosphere of ether, and the other of chloroform, I found, on removing the bowls, and permitting the bloody sides of the slides to remain downward, until all the ether and chloroform had evaporated, that no disintegration or marked change in the form of the corpuscle was observable under the microscope, on comparing them with the blood of a frog unaffected by an anæsthetic. This forcibly demonstrates the difference between exposure to *direct contact* and the *vapor* of chloroform, even out of the body.

\* Chloroform, its Actions and Administrations. By Arthur Ernest Sansom, M.B., London. Philadelphia: Lindsay & Blakiston.

"*Third Series.*—Over and again, in the presence of a number of gentlemen, I have placed frogs under the influence of ether, chloroform, and nitrous oxide, and examined their blood corpuscles immediately after without finding any disintegration or change in the form of the corpuscle. In one instance, a frog was so completely narcotized by chloroform that it died; the thorax of the animal was opened, the lungs cut out, and the blood obtained directly from that organ; and even here, where, if the inference of an altered blood was correct, there should have been discharge of nuclei, disintegration, or marked change in the form of the corpuscle, nothing of the kind was evident, as will be seen by the accompanying illustration, drawn from the slide on which the blood was placed. (Fig. 2.) As

FIG. 2.

Corpuscles from the lungs of a frog which died under the influence of chloroform.

already intimated, the experiments in this direction have been prosecuted on every available occasion within the past few months; and I have not confined myself to frogs, but, in the course of vivisections on a large number of animals (rabbits, dogs, cats, and pigeons), to illustrate my course of lectures on physiology this winter, when these animals have been placed under the influence of ether or chloroform, their blood has been examined, and no change in the form of the corpuscle has been evident.

"*Fourth Series.*—The examination of the blood of a number of human beings, drawn prior to and after having been under the influence of ether, chloroform, or nitrous oxide, for the extraction of teeth, has yielded similar results, as will be evident from the accompanying illustration of the blood, obtained from a patient (Fig. 3) while under the influence of chloroform. Any one accustomed to microscopical examinations will recognize the normal characters of the corpuscles, so far as it is possible to present them in a wood-cut.

"The results of these investigations

were recently presented to the members of the Microscopical and Biological Department of the Academy of Natural Sciences, illustrated by a large number of microscopical slides, and although some time has elapsed since the blood was placed on many of them, the corpuscles retain their form unchanged. . . . .

FIG. 3.

Corpuscles of a patient under the influence of chloroform.

"I cannot refrain from saying, when taking into consideration the readiness with which fluids absorb gases, that undue prominence apparently has been given by physiologists to the blood corpuscles as the carriers of oxygen to the tissues, and carbonic acid gas to the lungs, for it is reasonable to infer that the *liquor sanguinis* is actively engaged in this operation. After the most careful examination under the microscope, I have been unable to observe those modifications in the form of the corpuscles in venous and arterial blood, changing from biconvex to biconcave disks, and attributed to the absorption of the gases, of which so much is said in the books."

In a circular we have received from the office of the "Massachusetts Society for the Prevention of Cruelty to Animals," dated Boston, March 17, 1869, it is stated that the Society is doing a work which needs to be done, and relies upon humane people to sustain it. The names of its officers indicate that it has the sympathy of the best men in the State. But while we feel that Cruelty to Animals has lessened since its organization, yet we daily witness and read of transactions which prove the need of further effort. We are constantly invited to extend our work, and we desire and ought to do so, while there continues to be the cruel beating and overloading of horses on teams, horse cars and omnibuses—the under-feeding and cruel exposure of animals, the bleeding of calves, bagging of cows—while cattle are often without food or water

for thirty to forty hours on our railroads, while old, worn-out, diseased and galled horses are daily worked, and while there are various other forms of cruelty practised which need not here be named. But not only to check these cruelties do we ask support, but to help to educate men, women and children in love of animals, and through them in greater love for their fellow beings.

We take it for granted that individuals may favor the general objects of the Society, and yet differ on the subject of *civisections*, which has been so warmly discussed.

#### NOTES FROM UNION MEDICALE.

Dr. Edouard Fournié, physician to the Imperial Institute for Deaf-mutes, read a paper before the Imperial Academy, on a peculiar form of voice to which he gave the name of *La voix eunuchoïde*. It is characterized as follows: 1. The diapason is an octave above that of the ordinary voice; 2. The *timbre* has not the ordinary masculine quality, and approximately resembles the squeaking voice of eunuchs; 3. This voice is emitted by a perfectly sound organ, which, anatomically, does not differ from the larynx of a man with a normal voice; 4. Laryngoscopic examination enabled the author to ascertain that the foregoing characteristics are due to a functional trouble, or, in other words, to a vicious mode of emitting the sound; which consists in uttering the tone according to the "mixed register," and not in accordance with the "chest register;" 5. This bad habit is traced back to the epoch of the change of voice: in certain individuals the phenomena of the change of voice being accompanied by an inflammatory condition, which causes pain during the emission of vocal sound. . . . M. F. has adopted a system of vocal gymnastics for this abnormal habit of utterance, which, he says, always overcomes it.

Dr. L. Mandl reports a case of *gangrene of the lung*. Phthisis had been diagnosed by another physician. Dr. M. found the patient much reduced; keeping his bed; excessively annoyed by copious fetid expectoration; and having a very quick pulse. There was complete anorexia. Physical examination gave dullness, pectoriloquy, gurgling and "*souffle*" in the lower poste-

rior portion of the left lung. There was also a crepitant râle and diminished resonance beneath the clavicle of the same side. Nothing noticeable on the right side. There had been frequent hæmoptysis. . . .

Dr. Mandl prescribed two "flying cauterizations" on the left shoulder-blade; and fumigations of infusion of althæa with the addition of a small proportion of carbolic acid. Morphine was also given. During the first month of this treatment (May) there was diminution of the violence of the cough, and of the vomiting which the patient had previously suffered from. The sleep was more calm. In June the proportion of carbolic acid was increased. Pills of chloride of sodium were given. The appetite was satisfactory; digestion performed with facility; sleep improved; diminished sensation of weight in the side; slight diminution of expectoration. Subsequently, the fumigations having been for a time omitted, they were renewed with "essence" of turpentine made into an emulsion with glycerine. It does not clearly appear whether or not the carbolic acid was also used again. Another cauterization was made with Vienna paste. The patient began to walk about in July. In September convalescence commenced. In October Dr. M. ascertained the complete disappearance of the moist râles in the left lower lobe. Under the clavicle of the corresponding side jerking respiration persisted. But the general health was most satisfactory; and the patient returned to his usual avocations.

MINUTE ANATOMY OF THE SKIN IN ERYSIPELAS.—From a review in the *Gazette Hebdomadaire*, &c., we learn that the skin, as affected by erysipelas, has been microscopically examined by M. Vulpian, in France, on the one hand, and by R. Volkmann and F. Stendener, in Germany, on the other, with results in some respects conflicting. The reviewer, however, thinks that these explorations have thrown light upon several points in the pathological process in erysipelas; and have shown that there is a rapid and considerable infiltration of pus globules (leucocytes) into the derma and subcutaneous cellular tissue; a rapid disappearance of the infiltrated elements, by

absorption and speedy destruction; disturbance in the circulation, with some changes in the lesser vessels. These points the reviewer considers settled. The explorations were made on the dead subject at points where the erysipelatous process was at its height.

**TUBERCULOSIS OF THE CHOROID.**—In the session for Dec. 9th of the Berlin Medical Society, B. Fränkel reports two cases, where meningeal tuberculosis was diagnosed by the aid of the ophthalmoscope. In the first case, that of a girl of 6 years, vision and consciousness remained unimpaired until death, and no subjective symptom that could prove the existence of meningitis was observed. The second case, in a boy of 8, was so far similar, that the physician "was enabled, from the appearance of the eye alone, to establish the diagnosis, which otherwise would have been entirely uncertain." Hyperæmia of the retina was observed, and, close to the papilla, a white, roundish spot of about one-sixth the diameter of the latter. Three other such spots were afterwards discovered, all fully exhibiting the characteristics of tubercles of the choroid. For four weeks the patient "made no complaint whatever of his eyes; he read, wrote and saw as usual, had neither sparks before his eyes, nor photophobia." "Six weeks after the diagnosis of general tuberculosis was made, appeared the first distinct symptoms of tubercular meningitis." "Both children, at the time of the discovery of the tubercles of the choroid, were in the possession of full consciousness, and showed no subjective symptoms referable to the eye." The tubercles were observed to increase in size as the disease went on; and the autopsy showed the presence of many others in the choroid which had escaped observation during life. The base of the brain presented the appearances characteristic of tubercular meningitis.—*Allg. Med. Central Ztg.*, No. 12, 1869.

D. F. L.

**EXTRACTS FROM THE REPORT OF A CASE OF HOUR-GLASS CONTRACTED STOMACH.**—Dr. W. Thornley Stoker laid before the Society a specimen which he had recently removed from the abdomen of a female subject lying in the dissecting-room attached to the College of Surgeons. It was an instance of a peculiarly rare and interesting condition of the stomach—namely, the division of that organ into two portions, a right, or pyloric, and a left, or œsophageal, pouch. The en-

tire length of the two parts, from right to left, was rather more than twelve inches, and they were obliquely situated in the abdomen, the left being most superior. The œsophageal division, which was more or less globular in form, was the larger, having a capacity of thirty-four ounces; whilst the right portion, which somewhat resembled the usual form of the viscus, held but twenty-five ounces of water.

The constricted part between the two was about an inch in length by three-quarters of an inch wide, and had a peculiar twisted appearance, which became less apparent when the left pouch was distended, and which Dr. Stoker conceived might have acted as a valve, by so untwisting and opening the passage from one cavity to the other.

[Here follows a more minute description. No ulcer is spoken of.]

A careful examination showed that no abnormal condition existed in any other part of the intestinal tract, excepting that the duodenum, which crossed the spine in its usual situation, was somewhat larger than it generally is. As far as he (Dr. Stoker) could ascertain the history of the case, the woman, who was forty-three years of age, and who had been an inmate of the North Dublin Union, had died from lung disease, and had shown no symptoms referable to the state of her stomach.—*Dublin Medical Press and Circular*.

**THE SANITARY CONDITION OF NICE.**—It is, in fact, now being recognized that most people should leave Nice as soon as possible after the beginning of January, in order to avoid its winds and dust. The season consequently grows yearly shorter. Sometimes the winds hold off till February; but unhappily, as I have said, this year they are early.

There is another inconvenience and danger at Nice, which, inasmuch as it can be removed, ought to be brought again to the notice of the authorities. I mean the foul smells arising from the neglect of drainage. This is a growing evil that threatens the prosperity of the town as nothing else does; for there are numberless people who will come to Nice for pleasure if it is not necessary for health, but who would vanish on the outbreak of a pestilence. The rapidity of its growth is almost incredible, the apathy about sanitary laws disgraceful. During the last three years Nice, so far as the visitors' quarters are concerned, has almost doubled.—*Ibid*.

## Medical Miscellany.

**EXTRACT FROM THE REPORT OF THE TRUSTEES OF THE CITY HOSPITAL, BOSTON.**—The following is a statement of the number of patients treated during the past year:—Patients in hospital, Jan. 1, 1868, 141. Admitted, medical, 1,133; surgical, 880; ophthalmic, 61; smallpox, 4. Total, 2,219. Discharged, 1,875; died, 163; remaining, 181. Largest number of patients in hospital at any one time, 230; smallest number of patients in hospital at any one time, 137; daily average number of patients in hospital, 172. Medical out-patients, 3,851; surgical out-patients, 2,732; ophthalmic out-patients, 1,652; cutaneous out-patients, 559. Total, 8,794. Number of visits of out-patients:—medical, 9,672; surgical, 5,460; ophthalmic, 13,104; cutaneous, 1,520. Total, 29,756. By reference to the report of the Superintendent, it will be seen that although the number of patients treated has increased 33 per cent. for the year, the proportion of deaths is lower than ever before in the history of the hospital, being 7 3-10ths per cent. This fact, considering the number of severe cases treated, is very gratifying, and is a strong proof of the skill and fidelity of the Board of Physicians and Surgeons.

**AMERICAN MEDICAL ASSOCIATION.**—The following is a portion of a circular we have received:

*Meeting at New Orleans, May 4, 1869.*—I am authorized by the Atlantic and Mississippi Steamship Co., of St. Louis, to say that they will carry physicians and their wives to attend the meeting of the Association, at the following rates, viz.:—From St. Louis to New Orleans, each passenger, \$20.00. From Cairo to New Orleans, each passenger, \$18.00. From Memphis to New Orleans, each passenger, \$15.00. Returning—from New Orleans to Memphis, each passenger, \$15.00. From N. Orleans to Cairo, each passenger, \$18.00. From New Orleans to St. Louis, each passenger, \$20.00. The Company start a first-class steamer from St. Louis every 48 hours, Sundays included, and the usual time from St. Louis to New Orleans is about six days, and from Cairo to New Orleans about four and half days. Passengers can go on any of their boats at the above rates, which include meals and state-rooms. The steamer which will, however, take down the great body of physicians wishing to travel by the river, will leave St. Louis at 5 o'clock, P.M., on Wednesday, the 28th of April; Cairo on Thursday evening, after the arrival of the afternoon train on the Illinois Cen. R. R.; and Memphis on Friday evening, reaching New Orleans from Monday noon to Tuesday morning.

JAMES F. HIBBERD, M.D.,

Richmond, Ind.

**INTERNATIONAL PHYSIO-PATHOLOGY.**—To definitively settle the question of the seat of aphasia, it is proposed to institute a comparison between the American brain and that of other nations. If the organ of speech-making be where it has lately been claimed to be, the left anterior lobe of Brother Jonathan's brain ought to show something special in the way of development.

AN inquiry into the death of the patient at the Worcester Infirmary from the administration by mistake of carbolic acid as an enema has taken place. The case seems to have been one of pure carelessness on the part of the dispenser, who, having neglected to make the prescription up on the day on which it was ordered, dispensed it on the following day from memory, and at haphazard put on the bottle the name of the deceased. At a special meeting of the governors, a resolution was adopted, with but two dissentients, to the effect that the deceased patient's death had been caused by the gross negligence and misconduct of the dispenser, and recommending that he be prosecuted for manslaughter. There can be no doubt, however, that the chief cause of the accident was the ambiguous meaning of the word "injection."—*London Med. Times and Gazette.*

**THE FIRST MEDICAL WORK IN THIS COUNTRY.**—Thomas Thatcher, the first minister of the "Old South Church," Boston, Mass., was the author of the first medical treatise printed in this country.

DR. PAGET has been re-elected to represent the University of Cambridge in the General Medical Council, for a period of five years.

## MEDICAL DIARY OF THE WEEK.

MONDAY, 9, A.M., Massachusetts General Hospital, Med. Clinic. 9, A.M., City Hospital, Ophthalmic Clinic.

TUESDAY, 9, A.M., City Hospital, Medical Clinic; 10, A.M., Surgical Lecture. 9 to 11, A.M., Boston Dispensary. 9-11, A.M., Massachusetts Eye and Ear Infirmary.

WEDNESDAY, 10, A.M., Massachusetts General Hospital, Surgical Visit. 11 A.M., OPERATIONS.

THURSDAY, 9 A.M., Massachusetts General Hospital, Medical Clinic. 10, A.M., Surgical Lecture.

FRIDAY, 9, A.M., City Hospital, Ophthalmic Clinic; 10, A.M., Surgical Visit; 11, A.M., OPERATIONS. 9 to 11, A.M., Boston Dispensary.

SATURDAY, 10, A.M., Massachusetts General Hospital Surgical Visit; 11, A.M., OPERATIONS.

**TO CORRESPONDENTS.**—The following communication has been received:—Diseases of the Jaws.

**PAMPHLETS RECEIVED.**—Report of the State of the New York Hospital and Bloomingdale Asylum, for the year 1868.—Remarks on Dr. Sayre's Paper entitled "A New Operation for Artificial Hip-joint, in Bony Anchylosis." By Louis Bauer, M.D., of Brooklyn, N. Y.—Proceedings of the American Pharmaceutical Association at the Sixteenth Annual Meeting, September, 1868.

**DEATHS IN BOSTON for the week ending Saturday noon, March 27th, 120. Males, 53—Females, 67.**—Accident, 2—anaemia, 1—inflammation of the bowels, 1—congestion of the brain, 1—disease of the brain, 7—bronchitis, 1—consumption, 23—convulsions, 2—croup, 9—debility, 2—diarrhoea, 1—diphtheria, 1—dropsy of the brain, 4—epilepsy, 1—erysipelas, 3—scarlet fever, 7—disease of the heart, 5—hamorrhage, 1—hip disease, 1—disease of the kidneys, 1—disease of the liver, 2—congestion of the lungs, 4—inflammation of the lungs, 7—measles, 1—cerebro-spinal meningitis, 1—old age, 6—paralysis, 3—peritonitis, 2—premature birth, 4—puerperal disease, 3—scrofula, 1—suicide, 2—teething, 1—tumor, 1—unknown, 7—whooping cough, 1.

Under 5 years of age, 47—between 5 and 20 years, 8—between 20 and 40 years, 25—between 40 and 60 years, 19—above 60 years, 21. Born in the United States, 82—Ireland, 30—other places, 8.

### DISEASES OF THE JAWS.

By THOMAS WATERMAN, M.D., Boston.

I.—*Naso-pharyngeal Polypus. Extirpation preceded by Temporary Displacement of the Superior Maxilla.*—B. F. F., æt. 39. A polypus of the left nasal fossa has been steadily growing for four years. It is visible just within the anterior nares, can be felt behind the soft palate, and can be seen by raising the palate with a spatula. It is hard and firm to the touch, does not readily bleed, and is not accompanied by deafness. Its point of origin is plainly from the posterior part of the nasal fossa. The left side of the nose is distended by the polypus, giving to the face the characteristic expression accompanying similar growths.

In view of the size, and obviously fibrous character of the growth, as well as its inevitable tendency, no other mode of removal than its direct excision at its point of origin seemed admissible, and this could be effected only by removing the upper jaw in a way and to an extent sufficient to expose the whole nasal fossa.

*Operation.*—A vertical incision was made from the nostril through the upper lip, and the cheek dissected up freely from the bone. The maxillary bone was then sawed horizontally across just below the floor of the orbit, from its outer border to the nasal fossa; the intermaxillary suture was divided by bone-forceps, the mucous membrane of the hard palate having been previously incised along the median line. A broad chisel inserted into the cut made by the saw depressed the bone, fracturing it posteriorly at its connection with the palate bones. By this displacement and without any further detachment, the origin of the polypus could be easily reached; the growth, which consisted of many firm lobules, was cut and torn away from the sphenoidal bone into the cells of which it had penetrated. The point from which it grew was then thoroughly swabbed with Squibb's liquor ferri subsul-

phatis, care being taken not to bring it in contact with the cut surfaces of the displaced bone. No ligatures were required. The polypus being removed, the bone was replaced and held in position by a silver wire twisted around the incisors on either side of the median section, a cork wedge was placed between the posterior molars, and the lower jaw bandaged firmly against the upper.

On the ninth day after the operation the patient was out of doors, on the eleventh an attack of erysipelas confined him to his bed again for a fortnight, but with no detriment to the progressing union of the jaw, which was perfected sufficiently to permit the removal of the wire on Oct. 18th, five weeks from the date of operation (Sept. 14th). On Oct. 28th, he was discharged from the Hospital by his own request. He had been able for ten days or a fortnight to chew meat with the teeth of the affected side, so firm was the union, and there was no deformity of his face, the trifling scar of the lip being invisible under his moustache. Two or three days before he left, a triangular piece of dead bone, about one inch long and one-third of an inch broad, came out through his nose. It appeared to be a portion of the palatal process of the superior maxilla.

Temporary resections, or osteoplastic resections, as they are termed in Europe, are characterized by the displacement of a bone still partially held in place by the soft parts; and by replacement of the bone, which has been thus rendered movable, as soon as the extirpation of the tumor is complete. The traces of the method by which the surgeon obtained access to the tumor are thus effaced.\*

The result of these procedures, as well as that of complete excision of the upper jaw, illustrates the extent to which operations may be successfully practised upon the bones of the face which protect and enclose important parts, but are independent of vi-

\* Rapport sur les Progrès de la chirurgie, Paris, 1867; in this work a history of the operation of temporary displacement of the upper jaw may be found, also in the Sydenham Year-Book of Medicine and Surgery, 1862, pp. 271 and 295.

tal organs. The particular operation under consideration is undoubtedly a valuable resource in many cases hitherto requiring a still severer mutilation, but as shown in the case next reported it does not admit of universal application. The improvements of modern dentistry are available for the diminution of much of the deformity entailed by the entire removal of the superior maxilla; an artificial jaw of vulcanite not only restores the dental arch, but obviates the unsightly falling in of the cheek usually consequent upon this operation.

II.—*Pharyngeal Tumor. Ectirpation preceded by Resection of Superior Maxilla.*—J. S. I., æt. 33. Fourteen months since a tumor of the size of a hen's egg, springing from the vicinity of the left tonsil, was removed by the *ceraseur*. It was thought at the time to be probably malignant, but his recovery from the operation was rapid, and on examining his throat no trace of its existence or point of implantation can now be seen. Within two months his ability to blow air through the left nostril has gradually ceased, at present it is entirely obstructed. The right nostril is also partly obstructed, and to an increasing extent. His deglutition as well as respiration is difficult. On introducing the finger behind the soft palate a growth having a broad surface of origin from the basilar process of the sphenoid bone fills the left half of the space between the base of the skull and the posterior nares. The finger can with difficulty be swept around the tumor on account of the small space unoccupied by it, but its attachment and the constriction of its base can readily be felt. No part of the tumor enters the nasal cavities, it cannot be seen from the anterior nares, nor is there any external or visible deformity. The tumor is symmetrical in shape, bleeds on touch as it also does spontaneously or from sneezing, is firm and hard, though friable, and is not painful or sensitive. There is no enlargement of the lymphatic glands. It was not inspected with the aid of the rhinoscope. As the disease was inaccessible for thorough and complete removal, without the excision of the left superior maxillary bone, neither the division of the soft palate (*Mann*) nor the partial removal of the hard palate (*Nélaton*) offering any chance of getting at the tumor, that operation was performed Oct. 12th, by the method usually described as of Velpeau. Through the aperture thus afforded the tumor was rendered visible as well as accessible, presenting a round convex mass an inch and a half in diameter furrowed by the septum of the

nostrils. It was removed with the aid of curved scissors, the bone from which it grew was cut away with the gouge, although not apparently diseased, and the surface thus denuded, as well as the soft parts adjoining, were swabbed with Squibb's liquor ferri subsulphatis. Two or three ligatures only were required.

The tumor under the microscope proved to be glandular rather than malignant. According to Dr. C. Ellis, "it was composed of rather small nuclei, with pale nucleoli somewhat larger than those usually found in glandular growths, but resembling them in other respects. A few doubtful lobules and some fragments of lobules were also seen. There were also found some fibrous tissue and a few minute blood-vessels. Very few, if any cells, and those of small size."

On the third day from the operation the stitches were removed from the incision in the cheek; on the ninth the patient sat up, and on the fourteenth he was discharged.

In February last he visited the Hospital wearing an artificial jaw which, exclusive of the palatine arch, was not more than one inch in diameter, so completely had the cavity left by the operation filled up. The scar on the cheek was invisible beneath his whiskers, there was no falling in of the cheek, dropping of the lower eyelid, nor paralysis of the face. The tone of his voice was not noticeably nasal, and there had been no recurrence of the tumor.

III.—*Hypertrophy of Gums. Partial Resection of Superior Maxilla.*—M. A. S., a young woman of average mental capacity, æt. 27. She has never been in good health. Her mother and her nurse say that the disease of which she is the subject is not congenital, but ever since the patient herself can remember she has been asked "what is the matter with your gums?" She has repeatedly had abscesses about the month, gum-boils, catarrh, and suffered most of her life from thick speech, deafness, difficult deglutition and dull pain in the jaws.

On examination the gums are seen to be hypertrophied along each side of the dental arches, not uniformly, but more prominently at some points than at others. The principal outgrowths are in front of the canine and incisor teeth in the upper jaw; in the lower jaw they occupy the place of the molar teeth on both sides. In the palatine arch of the superior maxillary bones two projecting excrescences, having their attachment anteriorly, pass backward, concealing the soft palate; in the cleft between them the uvula can be seen. On passing

the finger into this cleft it can be swept around slightly, the soft palate and a small part of the hard palate not being connected with the growth. These excrescences feel quite hard and non-elastic. The portions which project backward are somewhat movable, and can be pressed up so as to touch the palate.

At various times several teeth have been extracted, and the patient thinks that this has caused the growth to shrink somewhat, but the changes have been slight during the last eight years.

On the 26th of June all the teeth of the upper jaw were extracted, and at the same time those portions of the excrescences of the upper jaw which concealed the soft palate were sliced off. The patient was discharged on the 3d of July, and reentered the Hospital Oct. 7th. The disease in the meantime had remained quiescent.

Oct. 9th, the whole of the outgrowths were removed with the gouge, and the dental border of the superior maxilla sawed off. The wounds healed rapidly, and on the 21st of Oct. the patient was discharged, with the cut surfaces granulating in a healthy manner.

The rarity of the disease has led me to report this case, the interest of which centres in the peculiarity and infrequency of such an hypertrophy, rather than in the result of the operation.

I find but three recorded cases of this disease, one by Prof. Gross,\* one by Mr. Pollock,† and a third by Mr. Heath,‡ occurring under the care of Mr. Erichsen, in Univ. Coll. Hosp. In the first two cases the disease was congenital, and returned to some extent after removal. A very remarkable specimen of this disease presented itself in the person of a female of feeble intellect, covered with a remarkable hairy growth, who was exhibited by a showman in this city some ten years ago under the name of "Bear Woman." The hypertrophy of the gums was even more conspicuous than in the recorded cases. It is a little singular that Mr. Pollock's case was characterized by an extraordinary pilous development, and the patient a subject of epilepsy. Dr. Gross's patient was a stunted and feeble-minded boy.

Under the microscope the disease presented a purely fibrous growth, without myeloid cells, distinguishing it from epulis, with which, however, it was little likely to be con-

founded, neither the general aspect nor the mode of its growth bearing resemblance to the distinct masses and interdental origin of that affection.

The gross appearances of hypertrophied gums resemble the disease called lampas, occurring in the horse. The latter, however, is an inflammation of the gums, propagated to the bars of the roof of the mouth, and rising to a level with and even beyond the teeth. It usually subsides without treatment, or only requires slight scarifications.

IV.—*Tumor of the Lower Jaw from a misplaced Wisdom Tooth. Operation for its removal.*—A colored woman, æt. 41, ten years ago noticed an enlargement of the lower jaw on the left side, near the angle in the region usually occupied by the molar teeth. No permanent molars had ever appeared on that side, and it was the patient's conviction that there never had been any deciduous molars. The enlargement of the jaw was principally of the alveolar border, and this finally grew to such a degree as to prevent bringing the teeth together. Under these circumstances, five years ago a portion of the tumor cartilaginous in density was shaved off. A new growth gradually replaced what was removed, and there is now an enlargement of the entire bone, firm, dense, inelastic, slightly irregular in outline, sensitive on the inside to touch, and whenever hard morsels are bitten upon. It is hardly of sufficient size to be visible from the outside, but can readily be felt, and it projects inwards about to the same extent. The jaw is perhaps double its natural thickness. For the last six months the tumor has been the centre of a radiating neuralgic pain constantly present, and so severe as to make the patient willing to undergo any operation likely to give her relief.

Removal of a portion of the continuity of the jaw being attended by disability and disfigurement, it was thought best to perform a temporizing operation, and excise so much of the tumor as could be from the inside of the mouth. In chiselling away the bone, which was dense and vascular, a well-formed wisdom tooth was found impacted in the jaw bone in a horizontal position. As this was deemed to have been the source of all the suffering as well as to constitute the tumor, no further steps were taken toward its more thorough extirpation. The operation was followed by complete disappearance of the pain. The wound rapidly granulated, and at the end of three weeks the patient was discharged at her own request.

\* Gross's System of Surgery, 2d edition, Vol. II., p. 534, fig. 331.

† Holmes's System of Surgery, Vol. IV., p. 18.

‡ Injuries and Diseases of the Jaws, London, 1868, p. 189.

The crown of the tooth removed was found to be enveloped by the membranous sac originally lined with enamel pulp, which having fulfilled its function had become detached from the surface of the enamel, and now remained as a capsular investment of that portion of the tooth. The sac thus formed was not distended with serous fluid into a "dentigerous cyst," as occasionally occurs, and an instance of which was reported in 1863,\* but retained its original proportions. The case must therefore be looked upon merely as one of impacted misplaced tooth, and the specimen is interesting from its deep-seated position, and as exhibiting the *pathogenesis* rather than the *pathology* of dentigerous cysts, in a manner all the more satisfactory from the rarity with which an opportunity is afforded for their study.

The subject of dentigerous cysts has been treated of at length by Mr. Salter.†

(The preceding cases of more than usual interest occurred in 1867, at the Massachusetts General Hospital.)

## TWO CHRONIC ULCERS OF THE STOMACH. PERFORATION OF ONE, AND DEATH AT THE END OF EIGHTEEN DAYS.

By CHARLES E. HOSMER, M.D., of Waltham.

The patient was an ice dealer, æt. 26 years, and of good general health. Served in the civil war for four years, and was well during that time, excepting an attack of intermittent fever. Had also occasional cramps in the stomach, with vomiting of a greenish fluid. About two years ago, while pushing a large block of ice up an inclined plane, it slipped; and, as he caught it with his pole, the end of this last came against the pit of his stomach, or near there. He was obliged, on account of the injury, to stop work; and, 3ij. of senna having been prescribed, he took, by mistake, the same amount of the tincture of arnica. Soon after this he vomited a dark substance that is said to have looked like blood; and from that time he was never well, though he attended to his business until the fatal perforation occurred.

There was generally free vomiting of a yellowish fluid about two hours after eating; without the food, but with relief, and usually without much nausea. Sometimes a day or two would pass without vomiting;

and several times he thought he saw blood in the matters vomited. Oppression at the stomach was nearly a constant symptom, and there was quite often a pain that he compared to the "cutting with a dull knife," with an occasional cramp for an hour or two; and, when going about in his wagon, he would lean forward and press upon the epigastrium. His appetite was quite good, and his bowels rather costive. In his general appearance he did not look sick, though he had lost flesh.

Early in the night of Feb. 9th perforation took place, and he died on the 28th at 7, P.M. The pain at first was intense, and was very greatly increased by motion; afterwards it was very considerably diminished, but occurred in paroxysms, and towards the last it was rather dull. Pressure, however, was very tolerably borne, and as well over the epigastrium as elsewhere. At first there was great pain, also, in the left shoulder, but this gradually subsided at the end of a week. To relieve the pain, there was given throughout about three grains of morphine daily, by enema. Tympanites was slight at first, but became very great after the ninth day, and so continued till death, causing great dyspnoea. Respirations from 30-50 per minute; and the pulse, which was about 70 at first, rose at last to 120.

On opening the peritoneal cavity, there was a large escape of offensive air. The organs were quite firmly adherent; and there was some lymph upon the surface, with about five quarts of pus. The small and large intestines were much distended with gas; and the liver was pushed very much upwards and backwards. The stomach was collapsed, and contained two or three ounces of a viscid secretion. In the anterior parietes, near the small curvature, and about midway between the two orifices, was an ovoid, shallow, chronic ulcer, about  $1\frac{1}{2}$  inches by  $\frac{3}{4}$  inch in diameter; and in the base of this last a perforation, of a rather oval form, about 3 lines in diameter; with thin edges, and looking as if a piece had been punched out. Almost directly opposite, and in the posterior parietes was a second chronic ulcer, more defined and deeper than the other, of an elongated form, and measuring  $1\frac{1}{2}$  in. by  $\frac{5}{8}$  in. This last had penetrated quite through the parietes of the organ, and perforation was only prevented by strong, old adhesions to the omentum. About the other ulcer there were no adhesions. Thorax not examined.

The very unusual time that the patient survived the perforation in this case was

\* Trans. Boston Soc. for Med. Improvement. Vol. V., p. 101.

† Guy's Hosp. Reports, Vol. V., 3d Series, p. 319 and Holmes's Surgery, Vol. IV., p. 32.

remarkable, as death usually occurs within forty-eight hours; and it may be a question whether the external injury above referred to, or the arnica, could have had anything to do with the formation of the ulcers, inasmuch as there were some gastric symptoms before these suspected causes occurred.

## ENUCLEATION OF THE EYEBALL.

By P. PINEO, M.D., of Hyannis.

Mrs. S., aged 64, was seized with inflammation of the right eye, in March, 1868. In July, 1868, I was first called to see her, at which time she was suffering much pain and discomfort from a staphylomatous condition of the cornea and inflammation of nearly all the tissues of the eyeball. The patient had been attended by an "Eclectic Doctor" until after the disorganization of the eye and loss of sight, and I failed to get any intelligent description of the character of the inflammation in its earlier stages, or of the progress of the disease. She probably had had irido-keratitis, with sloughing of the cornea, producing the condition present.

For the conjunctivitis, a collyrium of borate of soda was prescribed; for the pain, a solution of sulphate of atropia. She became more comfortable, yet suffering more or less, until January, 1869, when an increase of pain and inflammation occurred.

On again being called, I found distention of the eyeball, inflammation of its tissues, with severe pain, not only in the disorganized eye, but in the orbit of both eyes, with photophobia of the sound eye, which symptom had always been present more or less. Evidences of sympathetic trouble in the sound eye were unmistakable, promising to involve the loss of sight.

February 10th, I punctured the corneal cicatrix, giving exit to a purulent discharge, which gave some relief from the distention, although the pain and distress continued. At length I advised and strongly urged, what at first had been suggested, removal of the eyeball.

On the 20th inst., enucleation of the eyeball was done, with the assistance of Dr. George, of Centerville. The conjunctiva, which was greatly thickened, was first divided close to the cornea; the tendon of the internal rectus was then divided, and successively the other recti and the oblique muscles, and with a pair of small curved scissors the optic nerve was cut close to the globe, when the eye rolled from its

socket, leaving the capsule of Tenon unharmed. Scarcely a drop of blood was lost, except that which came from the engorged conjunctiva.

The patient slept quietly, under the influence of ether, during the operation, and, when restored to consciousness, very little discomfort was felt in the orbit. She rested well the following night—better than for many weeks before.

On the 21st inst. she was perfectly comfortable and happy, with no discomfort about the eye, and promising a speedy recovery.

The after-treatment consists in a single thickness of cotton cloth over the lids, kept wet with cold water.

March 12th.—The orbit and lids healthy, and ready for an artificial eye. The patient has had no pain since the operation. The remaining eye is quite tolerant of light, and gaining strength.

February 22, 1869.

[We are indebted to Dr. J. B. S. Jackson for the following additional particulars.—Ed.]

This specimen was exhibited in a fresh state to the Society for Medical Improvement. Dr. Coolidge having examined it, he subsequently reported that the retina was thickened but soft to the feel, of an opaque white color, detached from the choroid coat except at the entrance of the optic nerve, and extending in a funnel-shaped form about as far forward as the ciliary process. The same form of disease occurs in the brain, and was first described by Virchow as glioma. In its nature there is nothing malignant. The choroid showed some signs of inflammation. The capsule of Tenon was inflamed and adherent to the sclerotic; this last being healthy.

In a note received by Dr. Jackson, March 27th, Dr. Pineo states that on cutting open the eye, he found it "filled with a pus-like semi-fluid mass."

## PIN WORMS, AND THEIR HOMOEOPATHIC TREATMENT.

By CHARLES E. BUCKINGHAM, M.D.

THE *New England Medical Gazette* for February, 1869, contains an article on Entozoa, which is a light not to be carelessly placed under a bushel, if its merits be equal to the Editor's comments—"one of the most important discoveries of modern medicine."

Let us have the whole history, for it took two to discover it. Mr. E. C. Haserick, of

Lake Village, N. H., "claims to have made a new discovery in regard to the manner in which some intestinal worms in horses and other animals are propagated. He has observed that light and air are necessary to accomplish it, and the female avails itself of such means, finds its way to the lower portion of the rectum, protrudes the vulva beyond the sphincter ani, while it holds on, or grasps the mucous membrane within and discharges its eggs around the anus; these are hatched, in the short space of five or six hours, and make their way into the rectum. He has applied many remedies to destroy the larvæ, but without success, until he made the simple application of lard around the anus. This he has found efficient in every case. By renewing the application two or three times a day for a week the surface is completely protected, and the egg has no nidus for development; consequently, as the worm is short-lived, in the space of eight days the animal is freed from parasites. Encouraged by his success with animals, Mr. Haserick, supposing worms in children to be propagated in the same manner, recommended the use of lard in the same manner, and, as he reports, with equal success. I shall endeavor to investigate this matter, in a manner that will prove the truth or fallacy of this statement. Some observations which I have already made induce me to believe Mr. Haserick is right about the propagation of worms in animals."

The writer of the article then goes on to show that he has investigated and proved. *Veni, vidi, vici.* Listen.

"After many attempts I succeeded, on the 15th, 16th and 17th of January, 1869, in satisfying myself that the method by which the oxyuris vermicularis propagates is by depositing the ova outside the sphincter ani, and around the edge of the anus, where, in the space of a few hours, the worms are hatched and make their way into the rectum. In order to ascertain if the ova are thus deposited, I directed the parents of the child afflicted with the oxyuri, a few minutes after a paroxysm of itching and pricking pain in the rectum had subsided, to take a piece of damp black silk, and wiping the anus of the child with it, fold it and send it to me. To the naked eye nothing appeared on the silk more than a little mucus. This I placed in a microscopic cell, and under a one-fifth objective found that, on several occasions, I had succeeded in obtaining large numbers of the eggs, thus confirming the observation of Mr. Haserick."

The comments of the editorial depart-

ment ought to come next, but as they do not in the *Gazette*, let me ask you to allow them to follow in the JOURNAL. They are as follows, the italics being yours and not his.

"One of the most important discoveries of modern medicine, and which, *if fully substantiated*, will eradicate a very troublesome as well as common affection, was presented at the meeting of the Boston Academy of Homœopathic Medicine, on January 25, 1869.

"Dr. D. G. Woodvine exhibited, under the microscope, some beautiful specimens of the ova or eggs of the oxyuri, or common pin worms. *By careful investigation, he has ascertained that these eggs require light and air to hatch them.* For this purpose, they are always deposited outside of the sphincter ani, where in a very few hours they are hatched, and the worm then makes its way into the bowel. *Now, by keeping the parts for an inch or two around the anus covered with a thin layer of lard, the oxyuri cannot deposit their eggs, and as the life of the animal does not exceed seven days, they can be wholly exterminated in the most severe and troublesome case in that time. The amount of suffering which may be saved by this simple discovery is incalculable.*"

And now for the application. If a patient of Dr. W. is suffering from pin worms, his anus must be protected by keeping the parts for an inch or two around covered with lard for seven days; and to follow up the treatment with the certainty of success, he must refrain during the same period from breaking wind and sunning his backside.

## HAY FEVER OR ROSE COLD.

(Continued from page 128.)

This coryza comes on in irregular paroxysms, in which the eyes are red and watery, the lids, as she assures me, *very red, and perceptibly swollen.* At the same time they, as well as the nose, are the seat of an insupportable itching. Her sister has suffered from chronic urticaria for three or four years.

In spite of the irregularity of the paroxysms, I advised the sulphate of quinine, and, if this should fail, a course of the Bourboulé (alkaline) waters. Should I see the patient again, I shall apply local treatment to the pharynx, by a solution either of nitrate of silver, tannin or perchloride of iron. The tincture of iodine which I generally employ seems to me less indicated on account of its action on the naso-lachrymal mucus.

In this observation there are several very remarkable circumstances. The direct and collateral hereditary tendency appears to indicate a diathetic origin. The two sisters belong to a gouty stock; chronic urticaria and granular pharyngitis are not rare in gouty families. In the case of our patient, the coryza succeeded to the urticaria, and when we reflect upon the red and itchy swelling of the eyelids, coming on by fits and starts, we recall the urticaria which preceded the coryza, and which, like this, was characterized by an intermittent itchy congestion of other parts of the cutaneous surface.

We remember that the sister also has urticaria, so that it is no more than natural to infer a diathetic tie between these affections which succeed one another in the family and the individual. From a comparison of their characteristics, it appears not improbable that these affections may have a common origin, if not a great analogy in form.

The second form is the asthmatic; the coryza being only the prelude, and sometimes a very short one, to a dyspnoea in which the nervous element plays the principal part. The naso-ocular catarrh, which apparently constituted the whole disease in the first form, has but a very secondary rôle, or at least is thrown into the background.

I can do no better than to quote the following observation given me by the patient herself. I have thought it best not to modify the form, so expressive in its simplicity.

"In 1838, when 19 years of age, and in the most perfect health, I made a six weeks' visit to a cousin living in Normandy, on the sea-shore. There, as a pleasure, I took prolonged sea-baths, in rainy or cold weather, swimming and fatiguing myself without any thought of my health. Finally, these imprudences ended in a severe inflammatory fever, after which my voice broke entirely, obliging me, definitively, to my great disappointment, to give up singing. All the winter I suffered, and was obliged to communicate all my wishes by writing. In the spring I recovered my health perfectly, and continued well until our departure for Egypt in July, 1843, four months after my marriage.

"If I mention this first trouble it is because I have always, either rightly or wrongly, regarded it as the starting point of my Egyptian affection, which has remained by me eighteen years.

"We arrived at Alexandria August 4th,

1843, I being then about three months pregnant. On the next day I commenced to suffer from a feeling of suffocation; I was red, panting, my pulse was feeble and very rapid. This we attributed to the fatigue of the voyage, to a cold which I had caught in traversing Malta to change boats, to my condition, and to the excessive heat which we found at Alexandria. But on the night of the fifth I was in such distress from the suffocation and the accompanying palpitation that my husband was obliged to run to the consulate for a physician.

"Dr. X., a German, the only one who enjoyed general confidence, being away, he was referred to another who had a certain reputation. This one upon his arrival, although informed of my pregnancy, bled me freely, relieving me to such an extent that I thought myself cured. The next morning, however, the oppression, the palpitation, a whistling sound with respiration, and a dry, convulsive cough, came on almost instantaneously, and so severely as to drive me almost out of my senses.

"The physician bled me again from the other arm, but less abundantly than before, affording me relief for another twenty-four hours. At the end of this time, not knowing what to do for me, he called another physician, a countryman of his, in consultation. They gave me potions and pills of assafoetida, and sent me into the country, where I was carried on the 9th or 10th of August, and what I suffered there is beyond my power of expression. At times I was delirious, and stole out in the night to find upon the terrace the air which I craved. The physician came every day, sometimes morning and evening, and every two or three days accompanied by his brother physicians. Once again they bled me, and in three or four days' time 175 leeches were applied to me. I have since learned that they wished to provoke a miscarriage as my sole chance of safety. These men considered me in the last stages of consumption, and supposing me ignorant of their language, held their consultations in my presence, showing me their thoughts and giving me a poor idea of their science. At length, in the first part of September, the trouble passed gradually away, and I rapidly recovered my health without having miscarried. Toward the end of this year, as I was very heavy, and the blood appeared to trouble me, the physician insisted upon bleeding me again. He had ordered but a small quantity of blood to be taken, but the Greek barber opened the vein so largely that the opening could not be closed, and I had a

terrible fainting spell. This kept me in an enfeebled condition until my confinement, which was natural, although my poor little girl came into the world so weak and delicate that we kept her but four months. I should say that not being familiar with the language of the country, I was unwilling to trust her to an Arabian or Negro nurse, but exhausted both of us by nursing her myself. We lost her on the 16th of May, and I dragged on, feeble and careworn, but without suffering, until the 8th of June.

"The 8th of June I woke up with a feeling of oppression, and the symptoms which I had remarked the preceding August returned almost instantaneously; these were always the same, only more or less intense during three months of the year, from the 8th or 10th of June until the 10th of Sept., throughout thirteen years' residence in Egypt. During these three months my pulse was constantly very feeble and rapid. The symptoms rapidly decreased in intensity from the 25th of August until the 10th of September. The entire month of July was a continued paroxysm of sufferings, which were at times intolerable. I clung to the posts of my iron bed, in my struggles for breath; I could never stretch myself out at full length. Seated in my bed or an arm-chair, unable to support a close-fitting garment, coughing till I thought I should die, and yet preferring the cough to the deep sense of suffocation, which was the cause of slight fainting attacks; spitting large quantities of mixed blood and phlegm, or, when the cough gave way to the suffocation, of bloody froth. *I must not forget to say that the first symptom of my attack was a sneezing without a cold for a cause*; then came the whistling respiration, and a general distress increased by the dejection caused by the periodical return; finally the suffocation and palpitation came on together, so that I have never been able to judge which was the cause of the other. Toward the end of July each year my respiratory efforts became so violent as to raise my left shoulder to the level of the ear, making upon the whole left side of the chest a sort of cushion on which I leaned my weary head. No appetite at all. I lived nearly three months upon breakfasts of thin soup, a little cold beef tea at noon, a slice of watermelon, a cooked peach or a few grapes in the evening. I had a horror of meat or bread, and, indeed, so great were my sufferings if I ate a little more than I have mentioned, that I preferred to suffer from hunger.

"In the course of the month of April I

began to be irregular; either too soon or too late, and during the whole duration of the attack there was an entire suppression or irregularity. Sometimes twice a month, but nothing to speak of, water rather than blood. By the last of September everything had resumed its natural course. I slept soundly, gradually gained flesh, and got through the winters so well, that for many years we were always hoping that I might escape the next attack; but the disease was inexorable.

"All sorts of treatment were tried upon me; pitch plasters sprinkled with cantharides and tartar emetic, and covering my shoulders and back, from the neck to lower part of the kidneys. These were left on five days, and removed only when intolerable. My bleeding back was dressed with simple cerate. The second year I had two, the third I had one, and they only added one trouble to another.

"Tartar emetic ointment upon the breast, and croton oil upon the breast and back also, did me more hurt than good, because they irritated my nerves. Quantities of flying blisters were applied, one permanent upon the left arm; another year the cautery and dry cupping. I refused cupping and scarifying, because there was no snap-lancet to be had, and I could not bear the idea of the cuts made by the barber with his razor. I also refused a moxa which a French physician wished to apply to the middle of my chest. Another physician wished to place a seton in the back of my neck, but I was unwilling. I cannot say how many preventive treatments I underwent. Milk diets, strengthening diets, stimulating diets, cod-liver oil, ass's milk, turpentine, sulphur, a great deal of belladonna, morphine, lactucarium, wild cherry, assafetida, fumigations of all sorts, sinapisms.

"One summer, in the absence of our good Dr. Schledhanss, I was treated by Clot-Bey, who watched me as a curious phenomenon.

"He applied bladders filled with ice over the heart to stop the palpitation, and gave me no nourishment but lemon ice cream. I was very much relieved during forty-eight hours, but the reaction was terrible, and ever since that time I have had a pain in the left side, at times confining me to my bed.

"One thing alone had afforded me some, but not perfect relief; that was a journey to Cairo by boat. This voyage, however, I was enabled to make but five times, my husband's business being sometimes too pressing, the water in the canal Mahmoudy,

which leads to the Nile, being too low at other times. When I did reach the river, and especially when we arrived at Cairo, in spite of the torrid heat I breathed less painfully, and was able to lie down a little.

"Of the painful remedies the only one which afforded me any permanent relief was the thorough cauterization of the throat by ammonia. It was Dr. Burguières who tried it the first year that we knew him in Egypt. When we went to live at Cairo, I besought our physician each year to employ it, but he did the operation, in spite of himself, so slowly and timidly that the effect was much less satisfactory. As for the rest, I soon exhausted the different resources of medicine. The moist, hot climate was too much against me.

"At Paris, in the different leaves of absence which my husband took, in the island of Rhodes, where we lived three years, in France upon our final return, in the country in the first place and afterwards at Paris from the eighth to the 20th of June of each year, I experienced a regular return, although in a very much milder form, of this curious disease.

"Eighteen-years of this suffering had so nearly used me up, that, apart from my summer paroxysms, I was in a state of perpetual malaise and sometimes of utter prostration.

"It was at this time that I came to Dr. Gueneau de Mussy, who had the idea of employing quinine as a preventive, about the middle of May. This disconcerted the enemy, and the fatal month of June was safely passed. During a month only, from August 15 to September 15, I had a slight return of the trouble, a little cough, a little oppression and slight palpitation, more feebleness than suffering, in fact.

"I am, then, full of confidence for the coming year.

"I have forgotten to say that my paroxysm was accompanied not only by a contraction of the throat, but by a more or less complete loss of voice.

"The contraction of the throat persisted even during the winter, when my health was the best. The gesture as though untying an imaginary cravat was habitual with me; I was fatigued by the sense of discomfort which always increased toward evening. It is only since the end of last winter that I am nearly free from this, and it is only since that time that I have had breath enough to blow out a candle without a sort of suffocation."

[To be continued.]

VOL. III.—No. 10A

## Reports of Medical Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.  
CHARLES D. HOMANS, M.D., SECRETARY.

DEC. 14th.—*Internal Strangulation caused by a Fibrous Tumor of the Womb.*—Dr. JACKSON reported the case and showed the specimen.

The patient was under the care of Dr. John Flint, who furnished the following history of the case. She was an unmarried woman, 44 years of age, and always more or less feeble and dyspeptic. For the last eight or ten years she had been habitually constive, and subject to frequent attacks of severe colicky pain and obstinate constipation, with nausea, vomiting and great distention of the abdomen by flatus. These attacks lasted for a day or so, and were only relieved by free evacuations from the bowels. On the 8th of December Dr. F. was called, and found her suffering intensely. The abdomen was perfectly unyielding from the great distention, and slightly tender. Skin hot and dry; pulse 120-130; tongue dry and corrugated; great thirst and restlessness; frequent eructations and occasional vomiting. The acetate of morphia and fomentations were ordered; but as there was no relief in two hours, two drops of croton oil were given; followed by injections. As there was still no relief, the morphia was given through the night, and the next morning two drops of the oil were repeated. This last moved the bowels slightly during the day, but without any relief. The pain had never been so severe; and until her death, which occurred on the morning of the 12th, she was kept under the influence of morphia and ether.

Menstruation had never been irregular, nor unusually painful.

The examination was made by Dr. John Homans, who found the cavity of the pelvis completely filled by the enlarged uterus. The organ was of a rounded form, and contained in its posterior parietes a single, large, lobulated, rounded and remarkably defined tumor. The fibrous structure was not very distinct to the naked eye, but there was no appearance of arrested growth. The cavity of the organ was elongated, and its structure changed as usual in such cases. The large intestine upon the left side was as large as the stomach; and, the left ureter being pressed upon, there was atrophy of the kidney, with hydronephrosis.

DEC. 14th.—*Peculiar Form of Fibrous Tumor of the Uterus.*—Dr. SHATTUCK reported the case.

The woman was 58 years old, and had had a tumor in the pelvis for 23 years. For several years she had been very large, and for the past two months exceedingly distended. She never had any hæmorrhage from the uterus, and died after being confined to the bed about a week, suffering much from pain and distention.

The following description of the tumor was given by Dr. JACKSON:—

"It was situated in the posterior parietes of the womb, measured 8 by 10 inches across the cut surface, was generally pretty well defined, and at the fundus came close to the peritoneal surface. In structure it was generally tough, not distinctly fibrous, and had a pearly translucency; the appearance being peculiar, and unlike any of the ordinary forms of degeneration, for the most part. In its substance was a defined cyst about five inches in diameter, filled with serum, polished upon the inner surface, and containing a considerable quantity of uniform, opaque, rich yellow, firm substance, adherent to the cyst, and in the form of a reticulated mesh rather than a continuous layer. This substance suggested the idea of fat, but looked more like fibrin that had undergone some peculiar change. Other small serous cysts were also found; and I would say that, although they are often enough spoken of, I have scarcely if ever seen them before. There was also a cyst, two or three inches in diameter, that contained a fresh clot of blood, and yellowish, translucent fibrin that resembled stiff glue. This last I have several times seen in aneurismal sacs, and have an idea that it has been described as an amyloid transformation. There was also another cyst, filled with grumous, dusky-red clots, some of the translucent fibrin, and that was about four inches in diameter. This effusion of blood into a fibroid tumor of the womb is something that I have never before met with nor heard of; and I cannot but think that it had some pathological connection with the disease that was found in the cavity of the organ, and in that of the peritoneum. In the anterior parietes of the womb was a second fibroid tumor, 2 inches by 1 inch in diameter, whitish, dense, and somewhat degenerated. The cervix and os were healthy. The body of the organ was enlarged, and measured eight inches in length; and about midway there arose from the inner surface, and by a small peduncle, a soft, vascular, and perfectly encephaloid-looking

mass that must have been originally nearly as large as the fist. Nothing could look more like fetal brain; and I cannot but think that it was a malignant growth, though the microscopic appearances did not accord with this idea. The ovaries were healthy.

"Dr. Ainsworth, who made the dissection, states that the parietal and visceral surface of the peritoneum was covered thickly over with soft, vascular, pedunculated growths, from a very small size to that of a pear. The peritoneum was also ecchymosed; and its cavity contained about eighteen pints of serum, with a bloody fluid in the pelvis. I have several times met with ascites, complicated with and undoubtedly caused by soft, cancerous-looking growths that arose in large numbers from the peritoneal surface, and without disease of the organs; and I am inclined to think that the present was a similar case, though I did not see any of the growths referred to."

JAN. 11th, 1869.—*Case resembling Cerebro-spinal Meningitis.*—Dr. MINOT reported the case.

The patient was a little girl, 7 years old, who complained, Jan. 24th, '1868, of not feeling well, and had slight epistaxis; she walked out, however. In the night she vomited, and the next day was delirious, becoming stupid and drowsy in the evening. That night and the following day she was very delirious, talking incessantly. The pulse was 160 and the respirations 50 in the minute. An eruption of small, round, purple spots was thinly scattered over the chest, shoulders, arms and belly. They varied in size, from a mere point to four lines in diameter, but a few were much larger; they remained permanent on pressure. The tongue and throat were dry and brown. In the evening there was copious epistaxis. On the 28th she remained in the same condition. Pulse 168. She refused to swallow, and nourishment was given by enema. She was noticed to be deaf. In the evening the pulse fell to 144. On the 29th she was completely deaf, but there was less delirium; she began to recognize those about her. The spots continued as before, the tongue was coated, but moist, she slept well. The pulse in the morning was 144; evening, 120. Jan. 30th, the child was still completely deaf, but had recovered her consciousness, and began to take nourishment. The spots had disappeared. It was noticed that her head was drawn back, as she lay, and there was tenderness about the back of the neck. There had been no convulsions, rigidity of limbs

or paralysis. From this time she steadily improved, and might be considered convalescent on Feb. 6th. The head was less drawn backward, Feb. 1st; and became straight on Feb. 5th. The deafness continues complete to the present time, although all the other symptoms have disappeared. The treatment consisted in turpentine for the first few days, followed by bromide of potassium; with plenty of nourishment. For several days the medicines as well as the food had to be given by enema.

JAN. 25th.—*Eyebrow at Arch of Pubes. Artificial Rectification.* DR. J. P. REYNOLDS reported the case.

L. X. had the perineum moderately torn in her first confinement. There was partial external prolapse. Dr. Reynolds attended her in her second confinement, and after her getting up, she had a very successful operation performed by Dr. Hodges, the wound uniting throughout by first intention; the external prolapse disappearing. Great solicitude was felt as to the effect of the third labor upon the restored perineum. Early in the evening, at the time of rupture of the membranes, the head being still high in the cavity, the upper fontanelle was central in the pelvis, the frontal suture easily traced in its whole extent, the left ear near the symphysis, the point of the lambdoid suture reached with great difficulty on the right side of the pelvis and very high up. The descent of the frontal end of the head continued, without much gain from efforts at replacement made by the fingers. At half past ten, the left eyebrow having been felt at the arch, the vectis was applied, bringing the occiput promptly round to the pubes. Labor was soon completed without injury to the perineum. It had been decided before the labor, in accordance with Dr. Hodges's wish, to make free lateral incisions if the perineum seemed in danger, and this was accordingly done, though, as Dr. Reynolds has since thought, unnecessarily.

JAN. 25th.—*Severe Varicella in the Sixth Month, with threatened Uterine Action; Recovery.* DR. J. P. REYNOLDS reported the case.

A woman about six months advanced in her second pregnancy had been greatly fatigued by riding forty miles in the cars on the fifth instant, and by some succeeding imprudent exertions. On the eighth she had severe pain in the back and head, with constitutional disturbance, and on the following day an eruption of varicella of extreme severity appeared on her, and also on her child two years old. After the first day the pulse was of only moderate frequency, hardly rising above ninety-two,

and often scarcely accelerated, but the pain in the back continued with great severity for nearly a week, so as to require the exhibition of from one-half to two-thirds of a grain of morphia in suppository during the night to control it. There was much nausea and occasional vomiting, perhaps fairly attributable to the opiates employed. Painful contractions about the fundus frequently recurred, and the patient complained often of a sense of constriction around the abdomen, and of a feeling of weight, as of a stone, in it. Great anxiety was felt as to the result to the child of these symptoms, which continued with varying severity from ten to fourteen days. The patient is now able to sit up, is free from pain; while the foetal movements are vigorous and pulsations of the foetal heart clear and strong. The continuance of so free an administration of opium for several days perhaps involved some additional risk to the child, but there seemed to be no escape from the necessity of resorting to it.

---

## Medical and Surgical Journal.

---

BOSTON: THURSDAY, APRIL 8, 1869.

---

OUR readers and ourselves may congratulate each other that a former Editor of this JOURNAL occupies to-day the place he so ably filled a few years ago.

BERLIN, February 20th, 1869.

MR. EDITOR,—As you have expressed a wish to hear from me, I have thought that you may be interested in a short account of the Medical School of Berlin.

No one can have a correct idea of this, without understanding that it is only a branch of the great University where everything is taught which is considered worth teaching, not omitting dancing, fencing and riding.

The educational corps includes about one hundred and seventy ordinary and extraordinary professors and private teachers. These are selected from the best scholars of Germany, some having already acquired celebrity at other universities in the country. The names of some men are associated with several centres of learning. The Assistant or Privat Dozent who has shown marked ability at one place is promoted to some higher position at another, maybe again removed to fill the highest place at a third, and may finally, perhaps, return as professor to Berlin, where his first laurels were earned—*genuine laurels truly earned*. Although the idea of an hereditary nobility is far from being outgrown in this country, a genuine nobility is not overlooked. The profession is re-

ceived at Court, but the honor is considered so great, so limited by personal claims, that it is not shared by the wife.

This distinguished body of men is divided into the faculties of theology, law, medicine and philosophy.

In the medical department there are forty-eight instructors of different grades. It will, therefore, readily be understood that all branches receive proper attention. Some of the lectures are given in the large building, formerly the palace of Prince Henry, brother of Frederic II., presented by Frederic William III. to the University. Other departments occupy separate buildings, constructed for the purpose, that devoted to anatomy being, perhaps, three times as large as our Medical College. It contains a very fine amphitheatre, and rooms for the prosecution of the study of every branch of normal anatomy. In the same square are the large buildings occupied by the School of Veterinary Medicine.

On the opposite side of the street, in the grounds of the Hospital La Charité, stands the Pathological Institute, under the direction of Prof. Virchow. It contains two autopsy and two lecture rooms, laboratories for microscopical and chemical investigation, and a pathological museum. The course of instruction is very complete. On Mondays, students are taught by Virchow or his assistant the proper method of making autopsies. That there is a right and a wrong way is made very apparent to the bystander, and painfully so to the student to whom has been granted the privilege of the drill. On Wednesdays and Saturdays, Virchow devotes two hours to the exhibition and description of specimens, upon a few of which most of the time is spent. It is impossible to describe the accuracy of observation and philosophical interpretation of morbid changes which characterize these lectures. One sees the working of the same mind which years ago reduced to order the chaos of pathological anatomy. On three mornings in the week practical instruction is also given in pathological histology, in the same large, pleasant, well-lighted room, where there are seats for about a hundred students, with their microscopes. A third regular course on pathological anatomy is given four times a week. Here the whole subject is systematically taught.

Clinical instruction in medicine is given in La Charité by Profs. Traube and Frerichs, the patients being examined in lecture rooms before the class, and also visited in the wards at other times.

In all departments the instruction is thoroughly practical, using the latter term in its best sense. The prominent idea seems to be that of giving the student the best possible opportunity for personal observation, and teaching him to use the fruits of this in the most advantageous manner.

The University of Berlin has been described because it has been less frequented by physicians than that of Vienna, where the same general plan is pursued, though the number of short private courses at the latter place offers great inducements to those who, in a limited time, wish to study some special branch or branches. We have in both of these great schools a complete system, which seeks the best men and gives them every facility for the prosecution of science and the communication of it to others. In both, the students must first be fitted for their work and then submit themselves to thorough examinations before receiving certificates of proficiency. It is easy to understand why every civilized nation should be represented in the audience of the lecture room, and why we should be indebted to Germany for so much that is valuable in medical science.

Yours very truly,

C. ELLIS.

**HOUSE PHYSICIAN FOR THE INFANTS' HOSPITAL, NEW YORK.**—Our *confrère*, Dr. Dunster, Editor of the *New York Medical Journal*, who is also Secretary of the Medical Board of the Infants' Hospital, New York, writes us in relation to the approaching choice of a house physician for that institution (advertised in this JOURNAL), that "the appointment is an important one, and demands a *first-class man*, and the inducements offered are, I think, sufficient to secure such a one. The selection of the incumbent by *concours* has never been tried in any of our public institutions, but the plan must commend itself as the only true and just method."

In a "Note on the so-called carbolic acid, or coal-tar creasote," presented at the last annual meeting of the American Pharmaceutical Association, by EDWARD R. SQUIBB, M.D., the Doctor says:—

It is pretty well known that the creasote of the common market of late years has been made from coal tar, and that it consists mainly of phenyl-alcohol and cresyl-alcohol, often called carbolic and cresylic acids, in not very uniform proportions. . .

Of late, more critical examination has shown that these liquids are not acids at all, in the common acceptance of the word acid, and that they must, for the present at least, be considered as alcohols. The coal tar creasote of the markets at the present day must be considered practically as a mixture in variable proportions of phenylic alcohol or phenyl-alcohol and cresylic alcohol or cresyl-alcohol, with small and unimportant proportions of other organic compounds, the first or phenyl-alcohol being commonly in the largest proportion. The dark colored oily liquids met with in the markets, under the name of crude carbolic acid for the lower grades, and impure carbolic acid for the better grades, is this same mixture of these liquids in varying proportions, but commonly containing more or less tar, oil, &c., and is there-

fore in reality coal tar creasote. It is now not only inaccurate but positively incorrect to call this mixture (or either of its constituents) an acid, and the longer it continues to be so called the more difficult it will be to change it.

Solutions of the impure mixture were tried by Dr. Squibb upon the cryptogams which grow in the form of mildew on the brown stone fronts of houses where they are shaded from the sun, as in areas. The cryptogams were destroyed. The cresyl-alcohol was then separated from the phenyl-alcohol, and each tried separately. The cresyl-alcohol was found to be the more destructive of the mildew, in the proportion of at least two to one.

The comparative action of the two upon the sense of taste was then investigated. Ten persons were selected besides Dr. Squibb to act as tasters—these experimenters being chosen as having gustatory nerves corresponding in sensibility pretty nearly to a common standard. It was found in "prospecting" for tasters, that comparatively few persons could recognize a mixture of one part common alcohol in ten thousand parts of distilled water; but that many would promptly detect one part in five thousand. In no single instance did cross-examination, by change and confusion of bottles, and other efforts, succeed in materially altering or interfering with the decision made. The results lead to the conclusion that to the ordinary sense of taste the cresyl-alcohol is from five to ten times stronger than the phenyl-alcohol.

#### NOTES FROM L'UNION MEDICALE.

DR. FORT in a surgical memorandum remarks that among the numerous causes of facial neuralgia is one which authors do not notice, but which frequently occurs. This cause, almost certain to be a source of error to practitioners, is a lesion of the buccal mucous membrane, behind the molars, and produced by the evolution of a wisdom tooth. The functional disturbances brought about by this slight lesion are so intense as to lead sometimes to suspicion of more serious trouble.

M. Forget in a criticism of M. Fort's remarks, says it is very true that the evolution of wisdom teeth produces peculiar disturbances; and that the fact has already been pointed out by others. In a memoir published in 1828, on the various deviations of which the lower wisdom teeth are susceptible, Dr. Toirac, says M. Forget, reports six cases bearing on this point. In one of these cases the patient was subject to slight attacks of inflammation for a year after the left lower wisdom tooth began to appear. His cheek, not very much swollen, was extremely sensitive to the slightest pressure, while deglutition was almost impossible. The left tonsil was swollen, and the soft palate was very red. The posterior third of the crown of a wisdom tooth was found to be covered with a fleshy band, consisting of the

gum, which was of a violet color, painful, and slightly ulcerated.

A worse case was reported by Dr. Desirabode, in 1851. A man of 25 years committed suicide, and it was supposed on account of violent dental neuralgia. At the autopsy it was found that the left lower wisdom tooth was directed horizontally from before backwards, the roots being in apposition with the base of the ramus, and its crown applied to the posterior molar, upon which it exerted strong pressure. The gum was greatly swollen. No other lesion existed in the dental apparatus.

M. Forget cites a still more aggravated case. A man 26 years old had been for a long time affected with neuralgia referred to the alveoli of the molar teeth on the right side of the lower jaw. The entire ramus was tumefied, and to a considerable degree. Impeded articulation; swelling of the whole *masseter* region, so to say; hyperostosis of the coronoid process. M. Maisonneuve, having exposed the bony tumor, applied the trephine in search of the tooth. The result not being satisfactory, resection of the jaw was done, at the alveolus of the first molar, and the condyle was disarticulated. The bone having been divided by a section parallel to its axis, M. Forget found several purulent cavities which had burrowed into its substance. It was an instance of medullary osteitis of the ramus of the jaw extending to the interior of the condyle, which was hollowed out, by a little purulent cyst opening close to the articular cartilage. The severe symptoms and the structural lesions had for their point of departure the abnormal enlargement of the wisdom tooth, which was shut up in the base of the coronoid process, and rising scarcely to the height of a millimetre above the level of the alveolus which it had hollowed out for itself. The tooth was of twice the normal size, the crown of it abutting against the neck of the adjoining tooth, in such a manner that in order to take rank in the dental arch, it would have been under the necessity of displacing from below upwards the molar which opposed its upward growth. It was this obstacle which compelled it to develop in the interior of the bone.

We drew off the above cases under the impression that it might possibly help the general practitioner, now and then, out of an obscure diagnosis, to be apprized of them. Since doing so, we received the communication—published in to-day's issue—entitled "Disease of the Jaws," and containing an account of a case similar to some of the foregoing.

M. Personne, pharmacist of the Hôpital de la Pitié, in a paper read before the Imperial Academy, on the use of essence of turpentine in poisoning by phosphorus, gave the results of three sets of experiments made by him on dogs. All the animals of the first series to which he administered

phosphorus alone, died at the expiration of different periods. Those to which he gave the phosphorus, and then a few hours subsequently the essence of turpentine, evinced the phenomena of intoxication, but did not succumb. Finally, the dogs of the third series, to which he administered essence of turpentine immediately after the phosphorus, showed only slight indisposition. According to the author, the explanation of these results is to be found in the property possessed by essence of turpentine of preventing phosphorus from burning at the expense of oxygen, whether in the open air or in the animal economy.

**SVAPNIA AND SWEET QUININE.**—A few weeks since Mr. Frederick Stearns, of Detroit, Mich., had the politeness to send us a sample of Dr. J. M. Bigelow's purified opium, or svapnia, so called; also of "sweet quinine," said to be the invention of Dr. Wm. Bullock. Mr. Stearns is at present the sole manufacturer of these articles. Not being ourselves a judge of drugs, we turned our samples over to the President of the American Pharmaceutical Association. Since then, we have seen in nearly all of our American and Canadian exchanges, notices of these preparations, but have foreborne to echo these notices until we should meet with the formulæ for making the articles. This we have not yet succeeded in doing; nor are we aware that any formulæ have been issued. But we are now able to present a pharmaceutical estimate of the substances themselves from the pen of the Editor of the *American Journal of Pharmacy*:—

"Svapnia is a trade name applied by Frederick Stearns to the purified titrated extract of opium, suggested by Dr. J. M. Bigelow, of Detroit. The merits claimed for it are, first, that it is uniform in morphia strength; second, that it contains only the alkaloids morphia, codeia and narceia, combined with meconic (and perhaps thebolactic) acid. How far the manufacturers will be able to keep the composition uniform we do not know. If they can do what they claim to do, the preparation certainly merits attention. Neither the label nor the accompanying wrapper give the actual morphia strength, which, as it is said to be uniform, should be given. It is to be regretted that a substance so costly as opium should be rendered yet more so by making it a specialty. In our next we propose to give some further remarks in relation to this preparation, meanwhile hazarding the opinion that, medicinally, it is not better than the deodorized tincture of the Pharmacopœia.

"Sweet quinine, another novelty, is, according to the wrapper, quinia molecules coated with glycyrrhizin. That is to say, the alkaloid quinia, as precipitated from the sulphate, intimately admixed with the sugar of liquorice. It follows that it is necessary to avoid the use of acid or spirituous solvents in connection with sweet quinine, which immediately develop the bitterness—one by salifying the alkaloid, the other by dissolving it.

The quality of liquorice to mask the taste of quinine, aloes, &c., has long been known to some persons, and we know one physician who has long prescribed it with this view. There is no doubt that the opinion of Mr. Harrop, at page 117 of this number, is correct, that the glycyrrhizin in commercial extract is altered by heat, and that fluid extract of liquorice root is better than a solution of the extract for mixtures. We should think Tilden's extract of liquorice root, made in vacuo, would be far superior to the imported for this purpose."

**ULCERATION OF THE OS UTERI TREATED BY THE APPLICATION OF CARBOLIC ACID.**—Dr. Roe has been for some time in the habit of using carbolic acid as a local application in cases of ulceration of the os and cervix uteri, and has found it to yield results superior to any other topical treatment which he has tried. He has used it in cases where the whole round of other applications has been unsuccessful, and always with the most happy results. He agrees with Dr. Roberts, of Manchester, who last year drew the attention of the profession to the subject, in considering it a caustic, which, as regards its severity, may take intermediate rank between the nitrate of silver and strong nitric acid, besides acting as a disinfectant, a matter of no small importance in these cases. Dr. Roe does not use it in as strong a form as Dr. Roberts, and does not consider the strong acid necessary in very superficial ulcerations. A mixture of one part of the strong acid with two of olive oil seems to answer all ordinary purposes; but in cases of very deep ulceration the use of the strong acid may be called for. In such cases Dr. Roberts desires the acid to be liquefied by the addition of a very small quantity of water. This has not been found to answer the purpose in the Coombe Hospital, but it has been there discovered by Mr. Weir, that the addition of a few grains of camphor will dissolve the acid, and will, moreover, prevent it again becoming solidified, even at a freezing temperature.

The application of the carbolic acid to the os uteri is best effected by soaking a little cotton wool in the liquid, securing it by a string, and introducing it through a speculum, the string being left depending out of the vagina, and the patient being directed to pull it away on the second day. This procedure is repeated in ordinary cases about twice every week. If it be desired to apply the acid to the cervical canal, it may readily be done, by passing into it a gum elastic catheter smeared with the carbolic oil.

*Dublin Medical Press and Circular.*

**A CASE OF SUPER-FÆTATION.**—The *Weser Zeitung*, of Feb. 20, has something more about the singular birth at Schlieven, we lately referred to. It quotes from the *Dantzig Gazette* the following communication from the health commissioner, Dr. Preuss, of Dirschau:—

"To the many questions addressed to me from many quarters in regard to the singular birth at Schlieven, announced on the 6th inst., I may here reply as follows:—The facts contained in the report alluded to are correct. I was summoned on the first of February to Schlieven, to give my ad-

vice in the case of a child born the day before of a young shepherd's wife, with the aid of a midwife. It was a girl, in other respects strong and hearty, under the extremity of whose *os sacrum* (*Kreuzbeinende*) was a swelling of the size of two fists. Vigorous movements were plainly visible on the surface of this tumor, and within I felt the members of a fetus, which, from its size, would in ordinary cases be reckoned at five months. It was evidently a double creation. So far the case belonged to the very rare, but could not be considered unique. Rokitsansky speaks of it as follows in the first volume of his *Pathological Anatomy* (pp. 62, 59): 'Double creation by engrafting (*Einpflanzung*.) Cryptodidymus (Guolt) so-called fetus in fetu. A larger, complete fetus bears at some place under the skin or in the cavities of the body a second, smaller and incomplete.' In this class evidently belongs the case before us. What is novel, and, so far as my knowledge goes, unnoticed in literature, is the fact that not only the child which has been carried its full term is alive to-day, but the fetus also has in the eleven days after birth further developed and palpably increased in size, and that the movements in the tumor have increased, and at present are very strong. They cannot be motions of the viscera, transferred through the aperture, as if this were so, such motions would be observed in every hernial sac. The tumor is now four and a half inches long, three and a half inches wide and high, pear-shaped; the head lies underneath on the left, the rump above on the right. The junction has a circumference of eight and a half inches. Further particulars as to the progress of this case are deferred."—*Medical and Surgical Reporter*.

EXTRACTS from a paper read before the New York County Medical Society, Feb. 8th, 1869, by THOS. ADDIS EMMET, M.D. :—

Division of the cervix, for the relief of dysmenorrhœa and sterility, has been a favorite practice for years past with many of the profession. Scarcely any operation in surgery, however, has been proposed, where so little judgment, as a rule, has been exercised, and where so frequently its indiscriminate performance has even amounted to malpractice. A reaction has slowly taken place in the views of the profession regarding this operation, but from one extreme we may fall into the opposite error, as we have certain conditions of the uterus which cannot be relieved otherwise than by a division of the cervix.

Experience has taught us that both dysmenorrhœa and sterility exist frequently from causes having no connection with flexure or even with the uterus itself; that dysmenorrhœa is not always present with a flexure, while impregnation sometimes takes place when this deviation is well marked.

I have observed instances of long toleration of this instrument [the intra-uterine stem-pessary], and without bad results following its use, in the hands of skilful men, yet I have never known an instance of permanent rectification of a flexure resulting from loss of substance in the uterus, while it is my belief that as a consequence from its use, pelvic cellulitis is the rule and not the exception. I beg that I may not be misunderstood, for I have stated that I regard,

as a rule, a curvature of the uterine body as being a temporary result of disease, the effect and not the cause; therefore a mere division of the cervix under any circumstances cannot be relied on as a sole means of relief. And, moreover, that it is against the indiscriminate practice of the operation that I offer my protest, in resorting to a means, which, without judgment as to its propriety, or the necessary preparatory treatment before its performance and proper care afterward, is so frequently attended with the most serious results. I repeat, experience has taught us that a simple flexure above the vaginal junction will gradually disappear if a proper treatment of the uterine disease can be instituted, and that in this condition it is always an exception to the rule where it becomes necessary to resort to surgical means.—*American Journal of Obstetrics*.

FEMALE DOCTORS.—*The Feuille Médicale de St. Pétersbourg*, in noticing the invasion of the professional schools in that city by women, says that "since the nomination of Madame Kashevarova to the doctorate of medicine, a crowd of women are occupied daily in the dead rooms of the Academy on the dissection of bodies. The occupation is certainly not likely to render the women engaged in it very attractive, and can hardly be considered conformable to the mission of the wife, whose whole energy ought to be concentrated in the bosom of their families. They desert their proper function and consecrate themselves to labors which necessarily estrange them from their domestic duties. To this consideration must be added the hindrances which the simultaneous concourse of pupils of both sexes interpose to serious scientific occupation."

*The Union Médicale* says:—"It is obvious that this promiscuity of the sexes in our schools must produce strange results. But the partisans of free trade in female medical studies may reply, 'Why not have special schools for women?' In fact, there are such in America; but truth obliges us to say that they are not very flourishing even in the country in which professional liberty is pushed to the degree of eccentricity."—*Dublin Medical Press and Circular*.

BOSTON DISPENSARY.—The following are the statistics of this institution for the six months ending March 31st:—The number of new patients at the Central Office has been 6869, of which 4626 have been medical cases, and 2243 surgical. The number of new patients in the Districts during the same period has been 4645, making the total number treated 11,514. Whole number of patients since October, 1796, 364,246. Whole number of patients since July, 1856, 245,344. Whole number of prescriptions since July, 1856, 522,068.

SAMUEL A. GREEN,

April 1, 1869.

Supt.

WE encounter the sad announcement of the decease of Professor ROBLEY DUNGLISON. His magisterial position as author of the *Medical Dictionary* we all have used renders an elaborate obituary notice unnecessary. *Si quaeris monumentum circumspice*.

## Medical Miscellany.

It is known that the catheterization of the air-passages in asphyxia neonatorum is especially recommended, as it removes foreign substances inspired with the first respiratory attempt, the entrance of which into the trachea and bronchi prevents the proper performance of the respiratory act. Dr. Billmann, of Neustadt, reports (*Aerztl. Intelligenzblatt*, No. 49, 1867) a case of intense asphyxia in which he used immediately the catheter, without first employing those means usually recommended in such cases, such as cutaneous irritation, baths, compression of the abdominal walls, &c. He introduced a thin male catheter into the larynx of the child, and inspired strongly. With a bubbling noise, a thick, viscid, and somewhat bloody mucus was drawn into the opening of the instrument, followed immediately by a short, deep inspiration. Already after four or five repetitions of this method, the respiration became gradually regular, and the child cried, yet a loud rattling still continued. This rattling disappeared each time after the removal of the mucus by means of aspiration with the catheter, but it returned after a few aspirations of the child, additional quantities of mucus coming up from the minuter to the larger bronchi. After the catheter had thus been employed for some time, the breathing became perfectly regular and easy.—*American Journal of Obstetrics*.

ON THE FLUID EXTRACT OF LIQUORICE ROOT AS AN EXCIPIENT FOR QUINIA. By JOSEPH HARROP.—Dr. Harrop remembers having on several occasions added as an adjuvant powdered extract of liquorice, as per prescription, to quinine mixtures, but which, as far as he could judge, did not much conceal the bitter taste of the medicine. About the same time he had occasion to take some quinine, and on looking around for something to overcome its bitterness, he tried the fluid-extract of liquorice-root, which he thought would at least be nicer than the powdered extract, when he found it to completely conceal the taste.

The inference then may be that the glycyrrhizin, said to be the source of the sweet taste in the root, and described as a transparent yellow gelatinous substance, overcame the bitterness of the quinine, and that the principle is, in part, destroyed or impaired by the process of manufacture in producing the commercial extract.

Might not the fluid-extract or a concentrated tincture be used to more completely cover the taste of aloes in the tincture, of which Dr. Wood says "liquorice answers the purpose imperfectly?" also in other preparations having an unpleasant taste?—*American Journal of Pharmacy*.

DR. LIVINGSTONE AND THE PARIS ACADEMY.—The Academy of Sciences proceeded last week to the election of a Corresponding Member, in place of Dr. Dallas Bache, for the Section of Geography and Navigation. Three candidates were nominated: Dr. Livingstone for London, M. Cialdi for Rome, and Dr. Benjamin Gould for the United States. Out of 52 votes Dr. Livingstone

received 48 suffrages, Dr. Gould 3, and M. Cialdi 1; and Dr. Livingstone was accordingly elected by an enormous majority.—*Dublin Medical Press and Circular*.

THE TRICHINA IN SWITZERLAND.—The journals have announced recently the invasion of the Canton of Tessin, by trichinosis. Six persons having died of it in one family, M. Paganini, a veterinary surgeon, investigated the fact. He submitted portions of human muscle and of pork to microscopic examination, and found both of them crowded with a multitude of the trichinae.—*Ibid*.

THE Académie Impériale de Médecine, on the 16th of March balloted for a Member at Large, and elected M. Coste.—*Ibid*.

THE connection of W. A. Hammond, M.D., with the *New York Medical Journal* ceases with the March number. The Journal will continue under the editorial supervision of Dr. E. S. Dunster.

ALL Essays to be submitted for award of prizes at the next meeting of the American Medical Association, should be forwarded to the undersigned in time to reach him by or before the 25th of April.

S. M. BEMISS,

Chairman Committee on Prize Essays,  
New Orleans, La.

## MEDICAL DIARY OF THE WEEK.

MONDAY, 9, A.M., Massachusetts General Hospital, Med. Clinic; 9, A.M., City Hospital, Ophthalmic Clinic.  
TUESDAY, 9, A.M., City Hospital, Medical Clinic; 10, A.M., Surgical Lecture. 9 to 11, A.M., Boston Dispensary. 9-11, A.M., Massachusetts Eye and Ear Infirmary.  
WEDNESDAY, 10, A.M., Massachusetts General Hospital, Surgical Visit. 11 A.M., OPERATIONS.  
THURSDAY, 9 A.M., Massachusetts General Hospital, Medical Clinic. 10, A.M., Surgical Lecture.  
FRIDAY, 9, A.M., City Hospital, Ophthalmic Clinic; 10, A.M., Surgical Visit; 11, A.M., OPERATIONS. 9 to 11, A.M., Boston Dispensary.  
SATURDAY, 10, A.M., Massachusetts General Hospital Surgical Visit; 11, A.M., OPERATIONS.

TO CORRESPONDENTS.—The following communication has been received:—Preparatory Medical Education.

DIED.—At New York, 30th ult., Alexander H. Stevens, M.D., in the 80th year of his age.

DEATHS IN BOSTON for the week ending Saturday noon, April 3d, 91. Males, 41—Females, 50.—Accident, 2—aneurism, 1—congestion of the brain, 1—disease of the brain, 2—inflammation of the brain, 1—bronchitis, 2—cancer, 1—consumption, 16—convulsions, 2—croup, 1—debility, 1—diarrhoea, 1—diphtheria, 1—dropsy, 1—dropsy of the brain, 1—scarlet fever, 11—typhoid fever, 3—disease of the heart, 1—intemperance, 2—disease of the kidneys, 1—congestion of the lungs, 6—inflammation of the lungs, 8—marasmus, 2—old age, 2—peritonitis, 1—premature birth, 1—puerperal disease, 4—scalded, 1—scrofula, 1—disease of the spine, 1—tumor, 1—unknown, 10—whooping cough, 1.

Under 5 years of age, 31—between 5 and 20 years, 11—between 20 and 40 years, 25—between 40 and 60 years, 12—above 60 years, 12. Born in the United States, 58—Ireland, 22—other places, 11.

### PREPARATORY MEDICAL EDUCATION.

By SAMUEL KNEELAND, M.D.

THE medical profession, no less than others interested in the more general branches of what is commonly considered a liberal education, have doubtless read with pleasure and profit two articles in the *Atlantic Monthly* for February and March, 1869, developing the initiatory steps and the desirable consummation of what is there very properly styled the "New Education." Prominent among the institutions established to secure this rational and practically useful education is the "Massachusetts Institute of Technology," whose full and instructive fourth annual catalogue, embracing the names of more than 170 students, has been recently brought to the notice of the medical profession of the State.

Having carefully examined this catalogue, we felt, probably with many other physicians, that, had this school been established a quarter of a century ago, we should have been spared a tedious and comparatively useless toil of six or eight years up the hill of *classical* science, to find nothing on the top but a few dried roots and sapless branches of the same tree of knowledge, whose flowers and fruits we might have gathered by more accessible paths far below, had we turned aside from the old beaten road. Believing that many of the best years of the medical student's life are wasted in the ordinary course pursued in the preparatory schools and colleges, let us see if the "New Education" does not afford the much desired escape from the classical Juggernaut before whose wheels generation after generation of physicians have blindly prostrated themselves.

Something more than the examination of the tongue, the feeling of the pulse, a superficial knowledge of drugs, the treatment of mere symptoms, and the ability to prescribe in the hieroglyphics of a dead language, are now demanded of the educated

physician. He must be able to trace the symptoms to the hidden cause, from a knowledge of chemistry and physiology, without which no rational system of hygiene and therapeutics is possible.

The old method of education trained the mental faculties without special reference to the end in view, and under it we studied in an aimless manner, involuntarily throwing away the wheat and storing up the chaff. The new or technical education, dealing only with living realities, and throwing aside mental training merely as such, develops the powers of the individual in the path he is to pursue in life, teaching him at the same time precision of thought, habits of observation, and method and purpose in his studies. We must recognize that the practical training of the technical school is far better for the physician than the literary culture of the college; we have not time in our fourscore years to throw away a tenth part on the dead languages, which we know will never be of any use to us compared with the exact sciences which we now have the means of pursuing.

Bearing in mind, then, that medicine is a science, or rather a combination of sciences, to be pursued with the method and the spirit of philosophic reasoning, we may now ask ourselves, what do the technical schools offer to the medical student, as preparation for his profession, better than the time-honored colleges? As before intimated, chemistry, organic and inorganic, lies at the foundation of the science of medicine; in this direction does modern physiology point, to its recent discoveries must we ascribe most of the great improvements of the day, and from its future researches must we expect the elevation of therapeutics to a place among the exact sciences. The few lectures of the college course, without opportunity for experiment, are practically valueless to the student, who comes to the medical school without any knowledge of the principles of chemistry, and therefore unable fully to avail himself of the chemical course, even were it from the lips of a Davy or a Faraday; and this failure of the student to attain any useful knowledge of

chemistry is attested by many physicians who have attended the courses in the technical schools, finding out too late that their early training failed to give them this necessary foundation for their professional education. In the technical schools, which receive pupils at the same ages, and for the same time (if necessary) as the colleges, each student is provided with his desk and apparatus, and is required to perform, under the supervision of the professors, a large number of experiments selected to illustrate the laws of chemical action and the properties of all the important chemical elements. When a knowledge of the elements is obtained, analysis, more advanced laboratory practice, organic chemistry, and researches of special utility for the practice of medicine, successively and in properly graduated steps, follow. We think it is no exaggeration to say that a student who has passed two or three years in this course at a school like that of the Institute, and who has not even commenced the study of medicine, could teach nine out of ten medical graduates principles of chemistry as applied to medicine of which they were either ignorant, or of whose application in their profession they had not even dreamed.

Of similar benefit to the medical student is the course of instruction in theoretical and experimental physics and mechanics given in the technical schools, by which the principles of natural philosophy, embracing light, heat, electricity, galvanism, sound, the mechanical forces, &c., are followed in their applications in determining the physical properties of solids and liquids. This knowledge, ignored by the medical profession as a body, and cultivated only by the few among them who by taste or accident are led to its pursuit, is equally neglected in the colleges. Of its great advantage to the physician the experience of almost every one in the profession will bear ample testimony.

The great attention paid to the various kinds of drawing in these schools is a very important feature, and one which is totally neglected in the college system. The skilful use of the pencil, and of water colors and India ink, with and without the use of instruments, which enables the student to acquire a method of accurately delineating objects, gives him a training of the hand and eye, which will be of great practical value to him as a physician. The ability to use artistically a piece of chalk is an accomplishment which we have often lamented was not possessed by some of our best

lecturers on anatomy, physiology, surgery, and pathology.

A year or two before entering a technical school, may profitably be spent in the study of Latin, with enough of Greek to make the student familiar with the terminology and derivation of ordinary scientific words; but the course of six to eight years in studying the structure of these languages, and in becoming familiar with their literature, to the exclusion of the exact sciences and the modern languages, seems to be for the physician an inexcusable waste of time. Great stress is laid in the "New Education" on the study of French and German, as no one in this age, in any department of science, can hope to keep up with the progress of knowledge without an acquaintance with these languages. At the same time the English language is not neglected, and the pupils are constantly drilled in the structure and peculiarities of their native tongue, and are taught to express their thoughts with precision and elegance. In addition, the important study of construction and materials may be pursued to that extent that the physician may correct prevalent errors in building, warming, ventilating and lighting dwellings, prolific causes of disease and death; and may know how to arrange the sick room, and especially crowded hospitals and the homes of the poor and ignorant, with the best chance for the recovery of the patients. The principles of geology, zoölogy and physiology are also taught, rendering the student familiar with methods of study, which he is to pursue more fully in his preparation for the business of his life.

Having suffered from the inability to pursue a rational preparatory course for the medical profession, let us no longer be content to move slowly along in the old classic ruts, pursuing a round-about and tedious road, beginning anywhere and ending wherever chance decides. Here we have opened before us a new and direct avenue, beginning when the pursuit in life is determined upon—followed without useless and time-wasting incumbrances—and ending with the purpose gained, viz., the acquirement of a sound medical education. We are fast dividing into *special* practitioners, each with a favorite branch of the profession in which we aim to be *special* skilful; let us begin at the beginning in this matter, and study *special*ly, from our youth, what is to fit us for a medical practitioner.

Let us, then, confine our study of the dead languages to a year or two, and afterward, instead of wasting four more in a literary

institution, devote our time in a technical and practical school to the study of chemistry, physics, drawing, the modern languages, and such branches of natural science as will best fit us for the rational practice of medicine and surgery.

### CASES OF SUDDEN DEATH.

By EDWARD WARREN, M.D., of NEWTON LOWER FALLS.

IN the 60th volume of this JOURNAL, I gave an account of a case of sudden death, attributed to imprudent bathing, which occurred on the 17th of March, 1859. It was that cold March weather, in which the chill is rendered more penetrating by the melting of ice and snow. The boy, who had bathed with others in a pond, ran and overtook an open milk-cart, on which he rode for about two miles, talking freely to the driver, when he was seized with violent spasms of the muscles of the face, extending to the whole body, and resembling those produced by an overdose of strychnine. He was carried into a farmer's house close at hand; the usual remedies were immediately resorted to, but without any effect, and he died within an hour and a half from the commencement of the attack, the rigidity of the muscles passing off, and the whole body becoming entirely relaxed shortly before death. He was buried on the fourth day after, the body, according to a daily paper, presenting a remarkably fresh appearance, the color hovering about the lips as if life still lingered.

On the 18th of March, 1867, nearly the same day of the month, and the same hour of the day—about four in the afternoon—I was called to the same house where the former death took place, to see a young woman who had done housework in the family for some months. She was about 20 years of age, and of a rather full habit. She had gone through a severe fever at her home in New Hampshire the winter previous to this; and had been working to pay the expenses thus incurred. She had now been home upon a visit, and returned the 10th of March to Weston.

She left home very early in the morning, taking some provisions with her to eat in the cars, and rode about fifteen miles in an open sleigh to the railroad. In the cars she rode about sixty miles to Waltham, and from Waltham she was conveyed in an open sleigh to her abode in Weston, a distance of about four miles.

She arrived there in high spirits; had had a delightful visit; had paid her "Doctor's

bill" and other little debts. She said she was now ready to go to work harder than ever. She took a cup of warm tea, declining to take any solid food, as she said she had taken a sufficient luncheon in the cars. She then went up into her room, the chamber of a large, old-fashioned farm house, in which there was no fire. After some time the mistress of the house, fearful of the consequences of her staying so long in a cold room, called her several times, and, receiving no answer, went up to her. She was found lying upon the floor in a state of entire insensibility. Her clothes were wet through, apparently by a copious and involuntary discharge of urine. Help was immediately summoned, and she was brought down into the warm sitting room, where, until medical assistance could arrive, hot water was applied to her feet, and the other remedies employed which had been used in the previous case.

I found her in a situation the reverse of that described in the former case. In that instance, the aspect reminded me of the effects of an irritant poison, such as strychnine, while these symptoms resembled the effects of a narcotic. She was entirely unconscious. There was complete relaxation of all parts; the face was of a natural color, perfectly calm and quiet; the pulse very perceptible and regular; her whole appearance leading me to give a very favorable prognosis. I directed mustard poultices to be applied to the bowels and feet; the temples and whole head to be rubbed with a strong solution of ammonia, and ammonia and other stimulants to be given internally. Under these applications she seemed to revive, and several times raised her head and made efforts to speak, but immediately relapsed again into a state of entire *anéantissement*. On giving her a stimulating injection, a clay-colored discharge, of natural size and consistence, was obtained.

We pursued this treatment for about five hours, keeping up the friction of the limbs for the whole time; but without any good result. At the end of that interval, her state of unconsciousness continued; the whole body was of good warmth, the respiration moderate and regular, the pulse steady. Her whole appearance was that of a person in a quiet sleep. But from this sleep it had proved impossible to rouse her, the first favorable indications having gradually ceased. To make use of any more active measures I feared would only exhaust the vital powers remaining. I directed her to be placed in a warm bed, and

kept quiet, with the feeble hope that rest and the latent power of nature might do more for her than anything else.

About two o'clock in the morning, about four hours after I had left, I was called to visit her again, respiration and pulsation having ceased. When I saw her, I found no signs of vitality, except that the body retained its natural warmth, and the flexibility of the limbs.

The condition of the body in these two cases is that which is apt to occur in sudden death by lightning or by violence. As there have been some undoubted cases of recovery after the fact of death seemed certain, it might be a question whether, in cases like the present, a physician ought not to direct the body to be kept without exclusion from the air until actual signs of decomposition appeared. But in so doing, he exposes himself to the charge either of insincerity or ignorance in a case upon which every old lady feels competent to pronounce categorically. Many years ago, the question, "What are the signs of Death?" was brought up in the Boston Society for Medical Improvement. The proposer was absent, but Dr. John Ware remarked, "there are no signs of death," and the subject dropped. There was no reply.

In the first of these two cases, the boy had remained long enough in the water to be severely chilled; and the additional exposure of riding in an open wagon completed the fatal effect. Another boy, his companion in the water, walked home, and dropped down insensible in his father's yard. He recovered.

In the case of the young woman, the lethal influence was less powerful but more protracted. The morning ride, followed by stagnation of the circulation from long sitting in the cars, prepared the system for the result. Then the subsequent ride in an open sleigh, followed by going into a cold room after the circulatory action had been aroused by warmth, completed the fatal effect. So long as a hostile influence, like that of cold, acts steadily upon the system, the vital powers are strong in resistance; but let the cause be once removed, and the system is less prepared to sustain a second shock, though much milder. A recent English lecturer warns his hearers, that on the strength of their new convictions of the necessity of fresh air, they are in danger of forgetting the fatal effects of cold, which he says kills its thousands every week in winter. This, in the comparatively mild climate of England. It sometimes kills,

he says, by mere shock. It is a lethal influence which acts like an epidemic poison.

While upon the subject of sudden death, I may allude to two cases which occurred some years since, which show the difficulty that sometimes attends the prognosis.

About the year 1856, I was called in consultation one evening to a young woman of about 20, whom I had often attended. She was in a state of lethargy, from which she could not be roused. The attending physician informed me that she had applied to him in consequence of a violent pain in her face. He had given her some common remedy, I forget what, and thought no more about it until evening, when he was called to her in great haste, and found her in a state of insensibility. He had immediately given her a powerful emetic, which had operated very freely; and had then resorted to all the other methods within reach which are employed in such cases, but without any effect. I set in action an electro-magnetic machine, and kept up a pretty smart current from the spine to the extremities, alternately continuous and in shocks or jets. Her consciousness partially returned; she knew me, and was able to carry on some conversation, but sank again into perfect lethargy, and though partially aroused at times still relapsed.

After continuing the current for about four hours, in addition to other remedies, her condition appeared so unfavorable that, after consultation, we decided that her recovery was impossible, and that it would be useless to try any further measures. I left her, expecting her death to ensue in the course of the night. My surprise was great, the next morning, to hear that she had recovered her consciousness. I did not see her again during her illness, but I ascertained that on recovering sensibility she was quite blind. She was some days in recovering her strength, and after several days the blindness passed off. I always attributed the symptoms in this case to an overdose of aconite; but how or when given, was never known.

The second case did not terminate as favorably. Very early in the morning, I was called in consultation to see a young woman about 17 years old, in a state of stupor, from which she could not be roused. The attending physician informed me that she was recovering from an attack of pneumonia, and that he left, the preceding evening, two pills of a quarter of a grain of morphine each; one to be given at bedtime, the second four hours after, if the first was not successful in promoting quiet

rest. The first was successful; and on waking she appeared so much better that it was thought best to give the second. Whether from the effect of the pill, or from some unknown cause, a state of stupor came on, from which they could not rouse her. I had mustard poultices applied to the bowels and feet, the head bathed with a strong solution of ammonia, and a large dose of ipecac. administered, aiding the action of the emetic by irritating the fauces with a feather. Free vomiting was induced. She recovered consciousness, sat up in bed, and talked and laughed.

Supposing all the danger over, I recommended a cup of strong coffee to be prepared for her, to carry off the remaining effects of the opiate, and went home to breakfast. I had hardly reached home before I was summoned again in great haste. I found that the lethargy had returned. All our efforts now were ineffectual, and death speedily ensued.

#### GALVANISM AN ANTIDOTE IN POISONING BY GELSEMINUM SEMPERVIRENS.

By J. T. MAIN, M.D., Unity, Me.

BELIEVING the yellow jessamine to be a valuable remedial agent, and one that would be much more generally used and esteemed if it were not for the unpleasant, or even dangerous symptoms sometimes following its administration in medium doses, to individuals peculiarly susceptible to its influence, I think the following facts may be of interest:—

In the summer of 1866, I took, through mistake, one drachm of fluid extract of gelseminum sempervirens, and immediately started to see a patient suffering from paralysis. The patient resided some eight miles off, and before arriving I became nearly blind. Control over the upper eyelid was almost entirely lost. The flexor muscles of the hands and arms were paralyzed, while the extensors were nearly so. Sensation in hands and arms blunted, but not in proportion to loss of motion. My speech was somewhat affected. A very disagreeable sensation of the head was felt even before the muscles came under the influence of the drug, but my mind was quite clear.

In this condition I arrived at the house of my patient, and as I was incapable of using my hands (my legs did not suffer nearly as much), I directed the nurse to apply the galvanic battery to the patient, and as she was about putting the instrument

aside, I asked her to apply the poles to my hands, which she did, and I was instantly relieved. The relief received was not only instantaneous, but perfect and permanent.

I have tried the galvanic battery by way of experiment, several times since, upon those who were pretty well under the influence of gelseminum, and with like results.

#### SYRINGE FOR THE EAR, NOSTRIL, &c.

By J. RUSSELL LITTLE, M.D., Jamaica Plain.

A CONVENIENT syringe, for the ear, nostril, throat, &c., may be made on the plan of the chemist's wash-bottle, as follows:—Take a bottle of convenient size, with a wide mouth; fit with a good cork, which should be pierced with two holes on a line with each other, of a size to admit glass tubing No. 4 or 5 (this may be done with a proper cork borer, or with a brad-awl and round file).

Now take a piece of glass tubing, of size above mentioned, about five inches long, and bend it in the flame of a spirit lamp to a right angle, at about two inches from one end. Pass the short end through one of the holes in the cork. Another piece of glass tubing sufficiently long to reach from near the bottom of the bottle to one inch above the cork should now be passed through the second hole. Slip over the extremity of the latter tube a piece of rubber tubing, at the other end of which connect in the same manner a nozzle made of glass tubing drawn to a point in the flame of the lamp. The bottle being now nearly filled with fluid, and the cork and tubes adjusted air-tight, by blowing through the first tube a stream is forced through the second by the pressure of air on the surface of the fluid.

By fitting the spray tube in the place of the second an atomizer may be produced without the use of the balls and elastic tube generally used.

March 15, 1869.

#### HAY FEVER OR ROSE COLD.

(Continued from page 173.)

SUCH is the story of the disease, and it bears the stamp of truth. Thus, every year, at a certain time, she was taken with coryza and repeated sneezing; then succeeded an attack of asthma, lasting three months, with exceedingly violent paroxysms, more frequent during the night. There is no apparent family predisposition to the disease. Her father, who is still living, is not gouty. Her mother died very

young. As for herself, since her cure, she has several times suffered from pleurodynia, but can recall no other symptoms resembling rheumatism. Her son, who suffers from granular sore throat, has, during the whole summer, an obstinate coryza, more catarrhal than spasmodic, which leaves him in the autumn.

He inherited from his father a lymphatic element predisposing him to catarrh; but this catarrh returns at precisely the same epoch as the spasmodic asthma in his mother's case—a circumstance worthy of mention, since such coincidences are often an expression of some morbid hereditary influence.

When I saw this lady for the first time, in the Spring of 1861, she was thin and worn out by her long sufferings; she had had a cough all winter. The repeated summer congestion was beginning to leave its traces, and a slight degree of emphysema was detected by auscultation. It was in the Spring; I ordered a course of mineral waters at Eaux Bonnes, and toward the end of May I ordered several doses of quinine. At the usual time the malaise came on, the coryza, and soon the paroxysms of orthopnea, distinct and periodical at first, as they always had been during several days before they became continuous. Under the influence of additional doses of quinine the symptoms ceased.

The following year I used quinine again, and the summer affection did not appear at all. Three successive years I employed the same preventive treatment with perfect success.

Seven years have passed since then; the patient has undergone the severest mental trials and physical fatigues; during entire months she has watched beside the sick beds of her husband and father, but the cure is still permanent. The last two years only, in this exhausted condition, she has contracted an acute bronchitis, accompanied by a dyspnoea, which has no connection, according to her accounts, with her old trouble, in spite of its appearance at the same epoch. A few blisters and a soothing treatment, the bromide of potash among other things, soon overcame it. Being placed this year in more favorable conditions, she enjoys good health with the exception of a heaviness in the chest, which she has not had in this season for four or five years. Should this sensation, which is quite disagreeable, become more marked, I shall repeat the quinine in the Spring. As yet, I see no necessity for it.

I will add to this case another, that of a

lady who came under my care three years ago. Every Spring, towards March or April, she was taken with fever and an extremely violent coryza, which was soon followed by a dyspnoea, having all the characteristics of asthma. The paroxysms were cured, but the coryza was not affected by the quinine. The spasmodic and violent cough, the expectoration and the sneezing continued, and an explosion of these symptoms was brought on by the least chill. Every Spring the symptoms were the same. Her mother and another relative were affected in the same manner. This patient was of a lymphatic, lax, and anemic constitution, and belonged to an arthritic family. One of her uncles is a typical case of a gonty man. After having had sick headaches and asthma in his youth, he now has violent paroxysms of gout every year. In her aunts, I have found acne rosacea, chronic eczemas, neuralgias, and hepatic colics. Arthritism, under different forms, has stamped itself upon her whole family.

Dr. Fleury, one of the first in France to mention this form of asthma, which he had observed in his own case in 1852, devotes an interesting chapter to the subject in his excellent *Traité d'Hydrothérapie*. Previous to its first appearance he had suffered from attacks of the gout. His mother also was gonty.

After having tried a large number of remedies without preventing or overcoming this cruel disease, which returned almost at a fixed date, in the months of May or June, he had recourse to hydrotherapy, which freed him from the paroxysm. Enlightened by his own experience, he has successfully employed the same treatment in similar cases since. Among others is the curious case of a patient subject to a constant hæmorrhoidal flux, which ceased during the paroxysms. Shower baths directed upon the pelvis and thighs brought back the hæmorrhoidal flux, while the asthma disappeared at the same time.

We can compare this last circumstance with the interruption of the menses, in our patient, during the attacks. We can also note the attacks of gout which preceded the periodical asthma in Dr. Fleury's case, and which have returned several times since the cure of the thoracic trouble.

Enough has been said upon the characteristics of the affection, but before passing to the indications, I will dwell a few moments upon its pathogeny.

The name hay fever expresses the important influence attributed to the odoriferous emanations of hay in its evolution. Is it

the pollen? is it some parasite attached to these growths? is it the anthoxanthum odoratum, the aromatic folus of the grasses which cover the fields, as Dr. Gordon thinks?

It is certain that, in some cases, the odor of the hay appears to be the exciting cause of the paroxysms. The observations of Gordon and Elliotson leave no doubt as to the fact, although the latter is wisely reserved as to the determining cause of the symptoms. He gives, among others, the remarkable case of a lady patient observed by Dr. Payser.

The father of this lady had a sudden but temporary coryza every time he crossed a grass field in flower.

She, herself, every year, towards June, experienced a sensation of heat and fulness in the eyes, accompanied by redness and watering. To these symptoms there soon succeeded an irritation of the nasal mucous membrane and sneezing; then the inflammation spread to the throat and the trachea, with a sensation of heat and itching in the situation of these organs. At this time the dyspnoea was most painful. All these symptoms disappeared towards the middle of July. This lady had no doubt of their connection with the grass in flower. On the middle of August she could walk through the fields with impunity, whilst in June and July the neighborhood of grass would cause her the most acute suffering. If, at this time, she picked a handful of grass, the integuments of her hands became red and itchy; the same symptoms would appear if she employed dry hay in packing boxes. For the purpose of escaping the vicinity of hay fields during the fatal season, she took refuge at the sea shore in the roughest countries. Here she found relief when the wind came from the sea, but was less well when the land breezes blew. One day when walking at the foot of Harwich cliffs, she was taken with a sudden and violent paroxysm, explained, in the morning, when she learned that at the very hour of her walk, they were mowing a small patch of grass upon the crest of the cliff.

At another time, in the centre of a small town, at a distance from any grass, she was seized with a sudden paroxysm, and on looking out of her window, saw men making a stack of hay brought from a distance. Another time a paroxysm was brought on by her children who entered the room after having been at play in a barn filled with hay.

I might doubt the accuracy of these facts had I not seen others which present a great analogy to them.

Three of this lady's children, adds Elliotson, inherited this infirmity; a fourth had common asthma with this peculiarity, that paroxysms were brought on by the odor of guinea-pigs. Many similar facts are found in the books, enough, in my mind, to prove the influence of emanations from hay in causing the development of asthmatic coryza in certain individuals.

But although this influence is incontestable, we can see, even in the observations cited for its support, that the affection may appear without these conditions, even in the individuals most susceptible to its effects; thus proving that it is only an exciting cause. We also find, as I was just saying, analogous conditions in the etiology of common asthma. Certain odors, certain localities always, or at least during a certain period of life, provoke the paroxysms. I have come across two asthmatics in whom the odor of flax-seed meal had this effect. One of them seems to have a special susceptibility for this ordinarily inoffensive grain. It is impossible to make a poultice in his apartments without his discovering it and being seized with an attack of asthma. There are other cases in which the odor of bean flowers, or the odor of the cat, produces the same effect. The emanations of hay are indeed much more active than many of the substances feared by certain asthmatics.

A farmer of Normandy has said to me quite lately that, during haying time, both he and his laborers suffered from violent head-aches.

This circumstance is mentioned in a great number of observations, with all the more authority as the authors have drawn no conclusions from the fact, and hence had no preconceived notions upon its etiological bearing.

Periodicity is a characteristic of many arthritic affections. A spring-time periodicity is especially peculiar to them. I have often remarked that many diseases of an arthritic origin, which are recurrent or subject to periodical exacerbations, return especially at the times in which the gout of the joints most naturally shows itself. Neuralgias, head-aches, affections of the joints have exhibited this tendency: sometimes, even, the neuralgias have, like the gout, been marked by a nocturnal increase in intensity. Thus the characters of the original type are found in its derivatives.

I make this remark incidentally, without applying it to the asthmatic coryza, which comes on in the summer rather than in the spring; still the periodicity of this coryza

places it in the same category as the arthritic affections which generally manifest themselves by regular or irregular paroxysms.

If hay fever has been more often noticed in England than in France, can this be due to the greater frequency of gout in the former country? Finally, the fact noted by all observers that hay fever is generally an affection of the richer classes, may serve as a proof of its relationship to arthritism.

Continuing the study of these analogies, which, if not enough to prove a common origin, are enough to justify a further study of the question, I find, in one of my patients, a morbid condition due to the arthritic source; i. e., an urticaria, alternating with an asthmatic coryza, the latter appearing with symptoms such as an injection, an itching and a tumefaction of the eyes which recall the cutaneous affection to which it has succeeded.

Again, Dr. Payser's patient could not touch hay without an irritation of the skin of the hands, the nature of which cannot be exactly affirmed on account of the lack of details. Still its sudden appearance and its pruriginous character gave it a singular resemblance to urticaria.

Another remarkable analogy is found in the fact that urticaria, like hay fever, is often due to exterior causes, such as the ingestion of muscles, fishes' eggs, or shell fish, and occasionally of food harmless to almost all the world, such as rice and strawberries. I have met in my practice with five persons for whom this excellent fruit was a poison, and, a curious fact, those whose diathesis I could learn, either belonged to a gouty stock, or, later in life, had attacks of gout. Behind a vast number of nervous troubles, behind a vast number of bizarre functional anomalies stamped with a nervous imprint, we find arthritism.

I know that this view will be regarded as a heresy by many physicians who reject the majority of the diatheses, saying that they have not seen them. They remind me of the tourist who drove round a lake with his face turned in the opposite direction, and said there was no water. I believe if they have not seen the diatheses it is for lack of having looked for them. As to the analogies between the urticaria and the summer asthma, I wish to draw no conclusion from them. If it be admitted, as I believe, that both are due to arthritism, their succession and the analogy in their manner of development can be understood.

In my last cases of periodical asthma, I have noticed the existence of granular sore

throat. Was it a simple coincidence? Could not this sore-throat, which I have met with in other forms of asthma, intervene as a predisposing cause? It constitutes a source of irritation which might favor the determination of the morbid action to the respiratory organs. I have already spoken of the frequency of granular *pharyngitis* in children attacked by angina stridulosa, and I have given the same explanation of the rôle which it might play in the development of this affection.

The treatment should be based upon the general condition of the patient, the diathetic conditions in the midst of which the affection is developed, the functional troubles which characterized it, its progress and its localization.

If, as was the case with several of our patients, we can find, or, at least, suspect an arthritic substratum, we must order that hygiene which consists in avoiding at the same time all the causes of excessive stimulation, or of depression, sudden changes in the weather, damp cold, a lack of muscular exercise, in a word, all those functional aberrations and surrounding conditions which have such an incontestable influence over the gouty affections.

In those cases in which we can find an exciting cause, such as the emanations from hay, these causes must be avoided. The neighborhood of the sea, the fresh, pure air, often afford very marked relief.

Cold lotions, methodically applied, are among the hygienic indications of a disease, in which an over sensibility to atmospheric change appears sometimes to act as an exciting cause. They act as tonics, and the experience of all patients proves the impropriety and danger of a debilitating treatment.

Some physicians, Bostock, Payser, Elliotson, have considered some medicines of service. Lobelia inflata, the hypo-chlorides, solutions of chlorine in emanations, and in aspirations, and preparations of arsenic, have been tried, one after the other, with, it is claimed, some success.

The periodicity of the paroxysms caused me to prescribe quinine, and to it I owe the cure of the patient whose remarkable case I have given you. It seemed to me to take hold especially upon the spasmodic element and in the asthmatic form.

This is so true that in another case it checked the paroxysms of dyspnoea without affecting the catarrh. I have employed it successfully more than once in ordinary well-marked paroxysmal asthma.

When the affection returns at a fixed

period the use of quinine should be commenced seven or eight days before its expected appearance.

At the end of three years, I have been able to give up its use with one patient. In periodical diseases, whatever their nature, whether purely nervous or congestive, an interruption of the morbid habit during a certain time, sometimes suffices to put an end to it.

If the catarrhal element is well marked, and especially if it outlasts the attack, a sulphurous or arsenical treatment is indicated.

Even during the paroxysms, I should try arsenic if the quinine failed or seemed less indicated.

We should not forget to examine the pharynx and to check the granulations, if they exist.

In this case the perchloride of iron or the nitrate of silver are preferable to the tincture of iodine, on account of the action of this metalloïd upon the pharyngeal and naso-ocular mucous membranes.

The diet should be as nourishing as the state of the digestive organs will permit.

Such are the therapeutical teachings which can be derived from my cases. As in the treatment of many diseases, our present knowledge is but a stepping-stone. The construction of the edifice would require more and better arranged materials.

years ago, in fact, the only modern works on these affections at all known were the small works of Hardy and Bazin in France and the frequent editions of Wilson in England; but since the publication of the first part of Hebra, and especially within the past year or two, they have appeared with a rapidity which indicates a proportionate increase in the attention they are receiving in all parts of Europe. Journals, too, exclusively devoted to their study have been recently started in England, Italy, France and Germany. Special departments for their investigation are everywhere being established in connection with hospitals and clinics, and their treatment is universally falling more and more into the practice of men devoted to this specialty alone. In character and merit these books differ widely. Several of them are of little value, except to the authors, perhaps, as advertisements of their specialty, for they contribute nothing to our previous knowledge that is reliable; others are largely controversial, written to uphold individual theories respecting the pathology or nomenclature of this or that disease; a few are carefully prepared and valuable monographs on single affections or classes of affections; while but one or two only contain the recorded observations of master-minds in the whole field of cutaneous medicine.

The most recent of these publications are those the titles of which are above given. The first, just received through a friend in Vienna in advance of its publication there, is written by Dr. Neumann, a former assistant of Hebra, to whom the book is dedicated. As might be anticipated, therefore, its doctrines are found to be mainly those of his distinguished teacher, although published in a condensed form. It is on this account, and for two reasons, especially valuable; first, because half only of the great work of Prof. Hebra has yet appeared, and his views in relation to a large and important portion of skin diseases will remain unknown, therefore, to the profession generally for an uncertain period in the future; and, secondly, when finished it will be so comprehensive and inaccessible to general practitioners that a condensed résumé of his views will be greatly needed. It is chiefly in this respect that Dr. Neumann's book is useful, but not wholly so. He is the first to attempt to represent the changes in the tissues of the skin in the various diseases which affect it by figures drawn from microscopic sections, and although many of these illustrations are really more diagram than actual picture of the ap-

## Bibliographical Notices.

### A NOTICE OF SOME NEW WORKS ON SKIN DISEASES.

1. *Lehrbuch der Hautkrankheiten.* Von Dr. ISIDOR NEUMANN, Docent an der k. k. Universität in Wien. Mit 49 Holzschnitten. Wien: 1869. Pp. 368.
2. *Archiv für Dermatologie und Syphilis.* Herausgegeben und redigirt von Dr. HEINRICH AUSPITZ, Docent an der Universität Wien, und Dr. FILIPP JOSEF PICK, Docent an der Universität Prag. 1. Jahrgang. Erstes Heft. Prag. 1869. Pp. 162.
3. *Annales de Dermatologie et de Syphiligraphie.* Publiées par le Docteur A. Doyon. Première Année. No. 1. Paris. 1869. Pp. 64.

THE great number of books on Skin Diseases published now-a-days must astonish one whose knowledge of the literature of this branch of medicine is limited to what existed only a short time since. Not ten

pearances to be seen in the field of the microscope at a single view, still they serve the purpose for which they are intended much better than any verbal description, and are undoubtedly the result of reliable observation. The normal anatomy of the skin and its appendages, too, is well illustrated by figures taken mostly from the best works on histology. The study of the structural changes of the skin in disease has been hitherto almost wholly neglected; but recently particular attention has been directed to this branch of pathology in Vienna, as the paper on Keloid, by Dr. J. C. Warren, of this city, noticed in a previous number of this JOURNAL, and a similar article on Lupus erythematosus, by Dr. Geddings, of New York, both of which are illustrated by elaborate microscopic drawings and were published in Vienna, are examples. Such illustrations are of far more value to the student than the poor and highly colored pictures of the external lesions to be found in his text-books as characteristic of skin diseases.

The book is divided into a general and a special portion. The first contains a description of the anatomy of the skin and its appendages, of the various forms of eruptions or lesions it exhibits, and chapters on diagnosis, aetiology, therapeutics, and classification. In the second or special portion, the individual affections are arranged under the twelve classes of Hebra's system and described in a simple and condensed style, but yet at sufficient length to answer the purpose of a text-book for the student and a hand-book for the practitioner. The very latest views of the many observers who have grown up under Hebra's tuition will be found here recorded, some of which, as we shall see elsewhere, differ from those of their distinguished master. The matter of treatment is handled with that regard to detail so essential to the value of this part of the subject, and which distinguishes the writings of German dermatologists from those of other nations. A very full and valuable list of recipes useful in the treatment of skin diseases is appended to the volume. There are many points in the book which deserve a special reference, but as this is a notice and not a critical review, they must be passed over.

The Archiv for Dermatology and Syphilis meets a want which has long been felt by those interested in the study and treatment of these two classes of disease; for not only does it present in a connected form all that the reader has hitherto been obliged

to cull from an immense and ever-extending field of periodical literature, but it enables those who have hitherto recorded the results of their observations only at rare intervals in book form, to give them to the public without such delay, and stimulates others to publish what might otherwise never be made known. It is in no way like its English relative, a journal largely devoted to the dissemination of the views of any one man or school, or tinged through and through with editorial prejudice or egotism, but a fair and dignified channel, free to all who may justly claim to speak through it. Its value and success are assured by the character of its editors and the distinguished names associated with them as co-operators—among them Anderson, Bazin, Biesiadecki, Boeck, Hallier, Hebra, Köbner, Kohn, Landois, Mosler, Neumann, Reder, Sigmund, Wertheim, and Zeissl.

The promise which such names offer is fully sustained by the contents of the first number. As an introduction, we have a modest preface by the Editors, and a communication from Prof. Sigmund upon the necessity of special clinical departments for the study of venereal and skin diseases. The first regular article is from Prof. Hebra, upon the use of rubber cloth in the treatment of skin diseases, and of which a translation will appear in a future number of the JOURNAL.

Dr. Köbner, of Breslau, follows with a communication on parasitic Sycosis, the existence of which, as is known, is denied by Hebra and other authorities. It seems to me beyond question that there are two distinct affections of the beard, closely resembling each other, one of which is an idiopathic inflammation of the hair follicles, while in the other the same pathological condition is caused by the presence and growth of a fungus, and we cannot forbear expressing a critical opinion in this connection. I do not agree with Dr. Köbner in regarding this fungus as identical with that of Herpes tonsurans or ringworm, the Trichophyton tonsurans. I have often seen the rings of *H. circinatus* extend from the face into the beard, and there remain for many months, causing the destruction of the hairs, but never under such circumstances produce any of the peculiar and characteristic appearances of sycosis, and it seems highly improbable that the trichophyton, which always gives rise to a constant series of effects upon the scalp, as *H. tonsurans*, and as undeviating a succession of appearances upon the skin as *H. circinatus*, should upon the beard at one time

cause one peculiar set of symptoms, and at another time others entirely unlike them.

The next article is on *Lupus erythematosus*, by Kohn, in which the treatment of this disease is very fully discussed, and the action of caustics upon the skin considered at length. The surprising action of mercurial plaster in this affection, accidentally discovered by the writer, is for the first time announced; cases which had resisted treatment in Hebra's wards for years yielding to its use in from six to twelve weeks.

Prof. Hallier, of Jena, furnishes a long communication on the vegetable parasites of the human body, in which his peculiar views with regard to the nature and importance of these now much-talked-of growths are given, but differing in no way from those contained in his former writings on the same subject, which have been noticed to some extent in this Journal (October 1, 1868).

Dr. Zeissl contributes a short article on the so-called subcutaneous condyloma, which, according to him, is a monstrous hypertrophy of the cellular portion of the follicle.

The last of the original articles, on *Eczema marginatum*, by one of the editors, Dr. Pick, is important, as it must be looked upon as definitely settling a question about which there has been much difference of opinion. This affection was first described by Hebra as a peculiar variety of eczema, characterized by its localization upon the inner surface of the thighs, buttocks and lower abdomen, by its slow peripheral extension outwards while healing in the centre, the well-defined and elevated margin which marks its limits, and by the discoloration it leaves behind in its course. Some striking pictures of it will be found in Hebra's plates. In 1864 Köbner announced the discovery of a parasitic fungus in this elevated border, and his opinion that this plant was the cause of the disease. This Hebra stoutly denied, but since then experiments and investigations carried on by the former and Pick, the results of which are here given, show conclusively that *E. marginatum* is really a parasitic affection of the skin, caused by the presence of *Tricophyton tonsurans*, or, in other words, that it is only a variety of *Herpes tonsurans*, the peculiar appearances of which depend chiefly upon its seat, and are those of "a *Herpes tonsurans vesiculosus* combined with those of an *eczema intertrigo*."

The second part of the volume contains an exhaustive and carefully prepared notice of all recent articles in any way connected

with dermatology and syphilis, arranged under appropriate divisions, and is of very great value. The whole deserves the highest praise.

The French Journal, the *Annales*, also presents upon its title-page a long list of collaborators, among whom may be mentioned the following well-known writers on these closely united branches, dermatology and syphilis, to which it will be devoted: Bassereau, Bazin, Clerc, Devergie, Diday, Hardy, Hebra, Lancereau, Lee, Ricord, Rodet, and Rollet. With such resources at command, which, as will be seen, are the most eminent that France possesses in these departments of medicine, it can hardly fail to accomplish all that the editor promises in his preface. It is especially in syphilography, however, that we may expect, as the above list suggests, most that is novel and valuable, for it is among these observers that the widely diverse modern theories with regard to syphilis are mostly agitated. A mention of the contents of the first number will show how largely this feature will characterize the journal, and indeed, considering the state of dermatology in France at present, we could hardly expect a predominance in the other direction.

We have first a contribution to the study of *Blenorrhagic Rheumatism*, by Fournier, in which he maintains that the urethral lesion is the essential, efficient cause of the affection, that "it is the blenorrhagia which causes blenorrhagic rheumatism."

Then follows the first part of an article by Diday on the employment of ice in certain affections of the testicular apparatus. He finds it serviceable first, in the orchitis sometimes complicated by blenorrhagic epididymitis; second, in testicular neuralgia, (irritable testis); and third, in certain obscure states in which pain constitutes the predominant feature.

Rollet contributes the first of a very important series of papers on the venereal and syphilitic affections of the uterus; and Guibout a communication on Diatheses in skin diseases in a therapeutical point of view.

The bibliography of this number consists of a long review of Jeannel's recent work on prostitution in the great cities of the nineteenth century, and the extinction of venereal diseases. It closes with a review of matters pertaining to its specialty contained in contemporary journals.

The *Annales* will be published every two months.

BOSTON: THURSDAY, APRIL 15, 1869.

## NOTES FROM L'UNION MEDICALE.

*Trephining.*—M. Chassaignac considers this operation indicated in only two conditions: 1, when there is a lesion situated in a definite spot, the seat of which lesion is fully ascertained, and the effects of which may be suppressed by trephining; 2, when there are symptoms of general compression, with dilated pupils, which symptoms are tending infallibly to produce death.

*Discharge of Blood and Serum from the Ear as a Sign of Fracture of the Base of the Cranium.*—A child five or six years old fell from a third story window, and was carried to the Hospital *Sainte Eugénie*, apparently in a dying state. He lost so much blood from the right ear that, on his first day in the hospital, several folds of linen were completely soaked with it. M. Marjolin diagnosed, at the upper part of the cranium, a transverse depression, and found all the signs of fracture with depression. Revulsives and purgatives were employed, but no operation was done. The flow of blood continued in diminished quantity for three or four days, at the expiration of which it was replaced by a discharge of serous fluid, which went on for about twenty-four hours. When the serous discharge ceased paralysis of the left side suddenly set in. Treatment same as before. After a few days the paralysis subsided, the child completely regained its intelligence, and was beginning to walk about. Then, an endemic of croup broke out in the hospital, and the little patient died of that disease. At the autopsy, the only fracture found was a transverse one of the crown of the head. This was accompanied with depression of the fragments into the cerebral substance. Three or four convolutions were destroyed. The fracture did not appear to continue towards the base of the cranium, and no trace of fracture of the temporal bone (*rocher*) was discovered. The superior longitudinal sinus had not been opened by the fracture. There was no effusion of blood between the dura mater

and the upper part of the skull; but traces were evident of a vast discharge of blood between the two layers of the arachnoid.

During the discussion which followed the relation of this case (at the *Société Impériale de Chirurgie*), M. Trélat referred to the cases reported by MM. Ferry, Prescott Hewitt, and Morvan, in which bloody serum flowed from the ear without there being fracture of the base of the cranium. The lesion was either of the inferior wall of the auditory canal, or of the tympanum, or in the bones of the internal ear, the cavity of the cranium not being opened into. To authorize the inference that a flow of serosity from the ear has its source in the cavity of the cranium, it is requisite, according to M. Trélat, that: 1, this flow be not sudden, but that it follow—after a few days' interval—a discharge of blood; 2, that it be of some considerable duration; 3, that the fluid have the chemical characters and the peculiar reaction of the cephalorachidian liquid. Under these conditions a flow of serosity from the ear, said M. Trélat, is a veritable pathognomonic characteristic of fracture of the base of the cranium, while a simple flow of blood, not followed by a discharge of serosity, is not a pathognomonic sign.

*Fibrous Tumors complicating Pregnancy. Cases related at the Imperial Surgical Society, Paris, February, 1869.*—A woman was taken in labor at full time, at Argenteuil, Nov. 30, 1856. The midwife in attendance could not make out the presentation, although the parts were well dilated and the membranes ruptured. Soon a hand of the fœtus appeared at the vulva. A physician was immediately called, who tried in vain to turn the child. Another also failed. Thereupon it was determined to send her to Paris, and on the evening of December 1st she was admitted into the Hospital (*des Cliniques*). She was in an alarming condition, and Prof. P. Dubois was summoned at once. The infant was dead. The cord hung from the vulva, as also the hand and fore-arm of the child. Prof. Dubois at first thought that there was a considerable contraction of the pelvis. At this moment abdominal palpation gave no evidence of uterine tumor. The patient

having been etherized, Prof. Dubois and M. Blot (chef de clinique) made two unsuccessful attempts at version. The next day, after a bath and venesection, renewed attempts were made without success. At length, at the request of Prof. Dubois, M. Depaul, who was in attendance also, succeeded in bringing down a foot to the vulva. By drawing upon this foot, delivery was effected, though with the greatest difficulty. The head of the child was much flattened. At the moment of the passage of the head, M. Blot felt it make a sudden bound, as though it had passed a notable obstruction. The patient died the next day, after a chill, intense fever, and green vomiting.

Autopsy showed on the surface of the uterus and in the thickness of its tissue the existence of many tumors, one of which, having a pedicle two or three inches long, was retained in the pelvic cavity by extremely firm fibro-cellular bands. Thus the pelvic cavity was reduced to a third of its ordinary capacity, and hence the death of the child and mother.

Two other cases, under the observation of M. Blot, had a different termination.

December, 1867, Messrs. Blot and Pajot were called in consultation by M. Hugnier to a woman, aged 30 to 35 years, who had reached the seventh month of her first pregnancy. She had about a dozen fibrous tumors which could be felt through the abdominal parietes. One of these completely filled the pelvic cavity, and was so wedged therein that it could not be moved. The neck of the uterus was completely flattened out between this tumor and the symphysis pubis.

It was decided in consultation not to induce premature labor, but to await the usual changes incident to pregnancy. Three weeks later the tumor, following the natural ascent of the uterus, had risen from the pelvic cavity so as to allow a small portion of the head of the fetus to be made out by digital examination. The consultants decided to wait still longer.

Labor occurred Feb. 28th, 1868, the head of the fetus having, in the meantime, gradually become more accessible. As labor advanced the uterine contractions with-

drew the tumor more and more from the pelvis, and, on the rupture of the membranes, the head engaged in the superior strait, from which position at 9, A.M., M. Blot readily terminated the labor by forceps. Mother and child did well.

Last July M. Blot was called in consultation to a woman aged 35 years, for inflammation in the region of the uterus. She was two or three months pregnant, and was found to have a fibrous tumor filling the pelvic cavity and flattening the neck of the uterus against the symphysis pubis.

The inflammation having passed off, the pregnancy took the normal course. M. Homelle, the attendant, subsequently informed him that labor terminated naturally. The tumor rose above the superior strait, as in the previous case and by the same influences, and permitted the extraction of a living and healthy child.

The first case, unlike the last two, terminated fatally in consequence of fibrous adhesions preventing the ascent of the tumor.

M. Blot thinks that such tumors increase in size during pregnancy, and diminish after labor. In the case under his observation, the tumors had decreased about one-third.

In conclusion, according to his experience, no general rules can be given for management of fibrous tumor of the uterus complicating pregnancy. In a good proportion of cases labor may not be attended with very great difficulties, but when adhesions exist the child cannot be born alive, and the mother may succumb. Unfortunately, this last grievous complication cannot be made out beforehand.

At a subsequent meeting of the Society, the cause of the increase and diminution of such tumors was discussed, M. Guéniot maintaining, against others, that it had not been scientifically demonstrated that pregnancy was the active cause of either. He related a case in which six months after delivery there was not the least change in position, volume, or consistence of the tumor.

Prof. Brown-Séquard communicated to the Academy two facts which he had observed in connection with lesion of the *corpora testiformia* in guinea-pigs. The first was

the production of hæmorrhage seated uniformly under the skin of the ear. This form of hæmorrhage had never been before pointed out. The only sanguinary effusions produced by lesions of the nervous system which had been observed, were that into the kidney in diseases of the spinal marrow, and hæmorrhage of the intestine in lesions of the brain. Another not less remarkable result of lesion of the restiform bodies was the production of dry gangrene of the ear. Even when the injury of the corpus restiform was produced on one side only, the gangrene may show itself upon both ears; but more often it is on the same side with the wounded restiform body.

Another fact was alluded to by Prof. Brown-Séquard—that section of the sciatic nerve induces epilepsy when the face is irritated at a certain point, just as occurs after lesion of the spinal marrow. On this point M. Colin stated that he had often divided the lesser sciatic nerve of a horse, and had produced nothing but halting. The Professor replied that everybody had seen animals with the sciatic nerve cut, and which were not epileptic for all that. But, what had not been hitherto known was that by irritating certain parts of the face when the nerve had been divided, attacks of epilepsy had been provoked.

THE SIAMESE TWINS.—The *Gazette Hebdomadaire* has an article on the Siamese twins. We discover nothing in it additional to what has appeared in American and English journals. One fact, however, from the English investigations of the twins, had escaped our notice. Under the sphygmograph the pulse of Eng, who is the larger and the more robust, gave a more powerful impulse than that of Chang, whose arterial system is said to furnish evidence of organic senility. The *Gazette* says one of the brothers appears "called to" an existence of longer duration than the other; and that the day may come when will arise, for the first time, the question of detaching a living man from a corpse.

DR. AMORY kindly furnishes the following information with reference to ether in membranous croup:—

MR. EDITOR,—While studying in Paris,

two years ago, I was informed by M. Roger's *Interne*, with whom I was going through the "*Hôpital des Enfants Malades*," that the operation of tracheotomy for membranous croup was there *never* performed with the administration of ether. As a reason for this, it was stated that oxidation of the blood was prevented from a deficiency in the supply of air to the lungs, thus producing analgesia.

I have seen the operation there performed as often as six times, and always without the use of any anæsthetic. In these cases the children offered no resistance and seemed to suffer no pain. None of them died during, or for several hours after, the operation. Of these six cases four entirely recovered, and in the other two the operation was merely undertaken to mitigate the suffering of the little patients, and with little expectation of their recovery, there being mucous râles in one or both lungs before the operation. Membranous croup was very prevalent during that winter, and I saw some other cases terminate fatally which had been operated upon, though I was not present during the operations.

I mention this, as I know that in this part of the country it is the custom to etherize the patient before tracheotomy is performed. While a medical student, I assisted in one operation and just missed seeing another, in which the patient died *before* the operation was concluded; in the former case, I strongly suspected at the time that suffocation from the ether, and not the operation, was the cause of death, though much care was exercised in the administration of the anæsthetic.

I desire to call the attention of the profession to this, and should like to see in your *JOURNAL* an account of the experience of surgeons who have *not* used ether in this operation; as I have never seen any allusion in medical books or journals to the analgesia caused by membranous croup. If this is a fact, much time and exhaustion from struggling against the ether may be saved to the patient.

R. A.

LUXATION OF THE HIP IN A YOUNG BOY.—At the monthly meeting of the Suffolk District Medical Society, March 27th, Dr. Tuck related a case of dislocation of the right hip upon the dorsum ilii, occurring in a healthy boy 6½ years of age. He was playing "horse" and fell, his companion falling upon him. The usual shortening of the limb and turning in of the toes were present. The head of the femur could be

plainly felt upon the dorsum ili. Ether was given, and reduction was easily effected by manipulation; the thigh being first flexed upon the body, then rotated upwards and outwards, and finally extended, when the head of the bone slipped into place with a sharp snap.

This accident is noteworthy from the rarity of its occurrence in children. In fifty-one (51) cases of hip dislocation reported by Malgaigne,\* in only one was the patient under fifteen, and Hamilton† has collected only seven (7) instances occurring at seven (7) or under, out of eighty-four (84) cases.

[In the edition of 1863, nine (9) such cases are given by Hamilton.—D. F. L.]

EXTRACTS FROM AN ACCOUNT OF AN OPERATION FOR THE RADICAL CURE OF HERNIA. By J. FAYRER, M.D., F.R.S.E., &c.—The method of performing the operation is simple, but it requires some care and confidence for its effective completion. The fore-finger of the left hand, oiled, is inserted into the inguinal canal, and the scrotum invaginated is pushed before it up to the internal ring with firm and decided pressure. One ligature, strong and well-waxed, is then threaded in the needle, the point of which is insinuated along the palmar aspect of the finger on its radial side, until it has reached the extreme apex of the invagination; it is then forced through the abdominal parietes, and appears on a line with the anterior superior spine of the ilium; about  $1\frac{1}{2}$  or 2 inches internal to it. The needle is then unthreaded and withdrawn, to be threaded with the second ligature, and again introduced, this time on the other side of the finger to be pushed through the abdominal wall as before; this time transfixing a short distance from the point where it first pierced, but emerging through the same opening in the integument.

The needle is again unthreaded and withdrawn. The plug is now pulled into the canal, the apex being firmly tied against the apex of the invagination, and the threads firmly knotted over the small piece of wood. The operation is thus completed.

The plug is left *in situ* for three or four days or more, until pus appears to flow freely from beside the ligatures. These are then cut and the plug withdrawn. The discharge is gently pressed out, a pad and spica bandage are applied, and the patient is kept in bed and cautioned not to strain at stool for some days; as soon as the wounds have cicatrized, a truss may be ap-

plied, which should be worn for some months, especially when any exertion is made; it may gradually be left off when the tissues have become firmly consolidated. The time occupied in treatment varies from a month to six weeks in ordinary cases; if there be much suppuration, and that have burrowed among the abdominal muscles, there may be delay, and counter-openings may be necessary, but such cases are the exception. The only one was that of a native who was attacked with erysipelas and died of pyæmia, the result of cellulitis. . . .

There was thus a total of 67 cases, of which 46 were apparently successful; 9 were relieved; 11 failed altogether, and 1 died.—*Medical Times and Gazette*.

A REVIEWER, speaking of Dr. Murchison's views of the functions of the liver, &c., says:— . . .

At present we are very much in the following position. We do not know whence the glycocholic and taurocholic acids come, nor whither they go, beyond having a vague idea that they are useful in the absorption of fat; we do not know the origin of the so-called glycogen; and we only know that, normally, glucose is destroyed in passing through the lungs. As to the bilirubin and biliverdin-coloring matters, we have some idea that they are derivatives of cruorin, and that they are partly reabsorbed and partly expelled, in a changed form, along with the feces. This is certainly very little, but we fear it is only too just an exposition of the exact state of our knowledge as to the bile and its functions. . . .

As to the diagnosis of the cause of jaundice, Dr. Murchison also opposes Dr. Harley's doctrine that in jaundice from obstruction the bile acids appear in the urine, but not when the jaundice arises from suppression. He also rejects Dr. Harley's mode of testing for bile acids, inasmuch as it affords no means of separating the reactions of the urinary pigments from those of the bile acids.

The subsequent chapters on fluid in the peritoneum and on pain in the liver are also highly interesting, especially the latter. His remarks on the removal of gall-stones are, we think, sound and practical. He advises alkalies as most likely to do good. Such also is our opinion, but, in common with our author, we also hold that hygienic conditions must be carefully attended to. The great cause of gall-stones is sluggish bowels, and the great cause of sluggish bowels is indolent habits, still more if associated with high living. Of no malady can it be more aptly said that prevention is better than cure.—*Ibid*.

† Page 621, Edition of 1860.

## Medical Miscellany.

At a meeting of the Obstetrical Society of London, March 3d, 1869, Dr. Brunton read a paper on Twin Pregnancies, detailing seventeen cases of twins observed in his own practice, and nine cases obtained from friends. Of these cases, sixteen had children of the same sex (males or females), with two amniotic sacs. Nine had children of opposite sexes (a male and a female) in one sac; and in one case there were two sacs, and one male and one female child. The conclusion at which he arrived was that, if a male ovum came down from each ovary at one and the same time, conception taking place, we had here an explanation of the existence of twin males, and so for female ova. But if two ova came down from the same ovary, conception taking place, we had twins of opposite sexes (male and female), and this pointed to the function of the ovary—viz., that probably the ova cast off from each ovary are alternately male and female—in other words, each ovary casts off at one and the same time a male, or each a female ovum. In no case were the twins of the same sex in one bag of membranes.

Dr. Playfair remarked that Dr. Brunton had overlooked the cases of conjoined twins, which were never of different sexes, and yet must have had but one sac.

Dr. Brunton replied that he could not see that this fact disproved his theory. His observations were of natural cases. Moreover, in the cases of conjoined twin-monsters, there might have been a coalescence of the ova (males or females) from each ovary, producing a double monster of the same sex.—*Medical Times and Gazette*.

**CARBOLIC ACID.**—We think it necessary to put our readers on their guard against an incautious use of carbolie acid. It seems to be forgotten sometimes that this substance exercises a powerfully destructive action upon animal tissues, and that it is, in fact, a very strong caustic when concentrated. There is no doubt that many serious accidents have recently occurred from Surgeons not being aware of the properties of the remedy they use so freely. It must also be remembered that the direct application of carbolie acid, even in a diluted form, to a granulating surface, will often delay cicatrization, and tend to promote suppuration, whereas, if it is employed at a distance from the wound, it will tend to diminish the formation of pus. There is, moreover, a good deal of evidence to show that it tends to stimulate the circulation through the smaller vessels, and thus gives rise to hæmorrhagic oozing, from recently cut surfaces, preventing their primary adhesion. If, however, it be properly applied in a diluted form to the wound itself, and in some permanent and non-volatile form to the external parts, it will be found to have a powerful influence in retarding and diminishing suppuration.—*Ibid*.

It was intended that the quotation in our last issue credited to Dr. Harrop should follow immediately after the remarks of the Editor of the *American Journal of Pharmacy*, but by some accident a dislocation took place.

**HARVARD TO THE RESCUE!**—That young man who edits *The College Courant* (Yale) must be looked after. Hear him!

"An exchange speaks of President Eliot, of Harvard, as a representative of 'muscular Christianity,' and one who will bring her up to the front rank and infuse something of the spirit of modern life into her veins. The editor speaks as a son of Harvard, and from the tenor of his words we should infer that Harvard had heretofore not been in the front rank. We always considered Harvard not to be far behind any American College."

That is to say (our younger brother in the Editorial line intimates), he didn't know *before* that Harvard was so far *behind*!

**THE DIFFERENCE.**—Science may properly take cognizance of *sexual precocity*; but it is another thing for parents to seek to make money by exhibiting to the public indiscriminately the extraordinary mammary development of a three-year-old child.

THIRTY-FOUR students received the degree of M.D. at the Chicago Medical College the 23d of March. Two *ad eundem* and four honorary degrees were also conferred.

## MEDICAL DIARY OF THE WEEK.

MONDAY, 9, A.M., Massachusetts General Hospital, Med. Clinic. 9, A.M., City Hospital, Ophthalmic Clinic.

TUESDAY, 9, A.M., City Hospital, Medical Clinic; 10, A.M., Surgical Lecture. 9 to 11, A.M., Boston Dispensary. 9-11, A.M., Massachusetts Eye and Ear Infirmary.

WEDNESDAY, 10, A.M., Massachusetts General Hospital, Surgical Visit. 11 A.M., OPERATIONS.

THURSDAY, 9 A.M., Massachusetts General Hospital, Medical Clinic. 10, A.M., Surgical Lecture.

FRIDAY, 9, A.M., City Hospital, Ophthalmic Clinic; 10, A.M., Surgical Visit; 11, A.M., OPERATIONS. 9 to 11, A.M., Boston Dispensary.

SATURDAY, 10, A.M., Massachusetts General Hospital—Surgical Visit; 11, A.M., OPERATIONS.

**TO CORRESPONDENTS.**—The following communications have been received:—Paralysis of the Motor Nerves of the Eye—Physiological and Therapeutical Uses of Ergot.

**PAMPHLETS RECEIVED.**—New York State Inebriate Asylum Superintendent's Report, 1868.—Valedictory Address to the Graduating Class of the School of Medicine of the University of Maryland. By S. T. Wallis, Esq.—On the Treatment of Paralysis by Electrization, with an Explanation of a new Galvanic Apparatus. By A. D. Rockwell, M.D., New York.

**DEATHS IN BOSTON** for the week ending Saturday noon, April 10, 10t. Males, 51—Females, 53.—Abscess, 1—accident, 3—apoplexy, 1—asthma, 1—disease of the bladder, 1—disease of the brain, 4—bronchitis, 8—burns, 1—cancer, 2—cancerum oris, 1—consumption, 18—convulsions, 1—diarrhœa, 1—diphtheria, 1—dropsy, 2—dropsy of the brain, 4—dysentery, 1—scarlet fever, 10—typhoid fever, 2—disease of the heart, 4—infantile disease, 1—influenza, 1—disease of the kidneys, 4—locomotor ataxia, 1—inflammation of the lungs, 8—marasmus, 2—old age, 2—paralysis, 1—premature birth, 1—pyæmia, 1—rheumatism, 1—scrofula, 1—disease of the spine, 1—ton-sillitis, 2—ulceration of the legs, 1—unknown, 8—whooping cough, 1.

Under 5 years of age, 33—between 5 and 20 years, 12—between 20 and 40 years, 25—between 40 and 60 years, 17—above 60 years, 17. Born in the United States, 69—Ireland, 30—other places, 4.

### A CASE OF FOLLICULAR ENTERITIS.

By S. G. WEBBER, M.D.

THE notes of the following case were kindly furnished by Dr. Buckingham, who saw the patient in consultation.

A girl, 3 years old, ate heartily of pigs' feet for breakfast. This was the only error of diet which could be discovered at that time, though this child and her brother had always been badly fed.

She was first seen by Dr. Parker, about noon. Up to that time she had vomited a little, but no part of the pigs' feet was found in the vomitus. She complained also of tenderness of the teeth. A cathartic was administered, but no dejection obtained. Then enemata were given, which brought away, at first, dark and slimy dejections; afterwards, several greenish and slimy ones. The vomiting continued throughout the sickness, and towards the last partially digested blood was thrown up.

Four days from the commencement of the attack, Dr. Buckingham was called, and at 6 o'clock, P.M., there was no pulse at the wrist; hands and forearms were cold; the remainder of the body was warm. The face resembled the face of a patient in the collapse of cholera. There was constant restlessness and crying out, with hand on epigastrium. The abdomen was not tympanitic; it was full and hard in the neighborhood of the cæcum. Oleum terebinthinæ, by enemata, and tinct. opii p. r. n., were prescribed.

She died at 3, A.M., on the fifth day of the disease, after two enemata. There had been no dejection.

The brother, 10 years old, was attacked with similar symptoms at the same time, but soon regained his health.

After the death of the girl, it was learned that before her sickness she occasionally complained of blindness.

I was requested by Dr. Buckingham to examine the deceased child.

VOL. III.—No. 12

The body was well nourished, with a large amount of fat. Rigor mortis was moderately well marked.

Lungs, heart, liver, spleen and kidneys were healthy; there was no sign of disease in any of the above organs.

The ileum, for about a foot above the cæcum, was very much congested; higher up, the congestion gradually faded away, and at two feet from the cæcum it had entirely disappeared. The upper part of the large intestines was also congested.

The mesenteric glands corresponding with the diseased intestines were enlarged, and in the acute angle formed by the junction of the ileum and cæcum, there was a large, indurated, nodular mass, composed of many swollen glands united.

The stomach and intestines were opened. The stomach contained a dark fluid, seemingly partially digested blood. The small intestines contained a similar fluid, which was black in the upper part of the duodenum, and changed gradually to a dark-green color towards the ileum. The cæcum contained a gelatinous substance. The rest of the large intestines was very nearly empty. The mucous lining of the stomach showed many spots, varying in size, where the smaller bloodvessels were much injected and unusually visible.

The interior of the small intestines, over the space corresponding to the congested portion, and the whole of the large intestines, were more or less thickly covered with small elevations filled with pus, each with a dark depressed spot in the centre; evidently inflamed follicles. This change was most marked in both small and large intestines in the neighborhood of the cæcum. The ileo-cæcal valve, and the parts in its immediate neighborhood, were much congested, and apparently all the follicles were inflamed. This great change, with the pressure of the mass of the glands in the angle, must have very much if not quite obstructed the passage through the ileo-cæcal valve.

Peyer's patches, for a distance of a foot and a half from the cæcum, presented a singular appearance. They were en-

[WHOLE No. 2147.]

larged and prominent, elevated nearly a sixteenth of an inch above the mucous surface, and had a brush-like appearance. The patches above that distance were abnormally distinct and gradually became normal. Also, the follicles were abnormally distinct for some distance above the region where they were most diseased.

The follicles of the large intestines were less affected the further the distance from the cœcum; but there were diseased follicles scattered thinly over even the lowest part of the gut which was removed, nearly to the end of the rectum.

The appendix cœci was healthy.

The specimen was shown to Dr. J. B. S. Jackson, who considered it a case of acute folliculitis.

The head was not examined.

No microscopic examination was made.

#### REMARKS UPON A CLASS OF OBSTETRICAL CASES.

By GEORGE CAPRON, M.D., Providence, R. I.

THE class of obstetrical cases to which I would respectfully invite your attention is that in which the head of the child is the part last expelled; whether this occur spontaneously—as in cases of presentations of the breech, knees or feet, or artificially—as in turning in presentations of the arm or shoulder, and other cases requiring that operation. It is a well-known fact that in these presentations a large percentage of the children are lost, and that death in a large proportion of the cases is caused by compression of the funis during the last stage of labor. The percentage is differently estimated by different authors, varying from twenty to thirty-three per cent. The greater estimate probably falls short of the truth; I think I do not err in saying that in primiparæ, it amounts to nearly or quite one half; and it is doubtful whether the greater success in the case of multiparæ reduces it below thirty-five or even forty per cent.

NOTE.—In this estimate of the percentage of loss, reference is had to the *whole class* of cases. Statistics based upon breech presentations *alone*, which is the most favorable variety of this class, would show much more favorable results.

Every practitioner of experience must often have been disappointed and indeed mortified (to say nothing of the emotions prompted by humanity), by having a fine, healthy child die in his hands, notwithstanding his most strenuous efforts to save it. Among our Catholic patients—who believe

the baptismal rite essential to insure the infant the light of Heaven—we are made to feel our responsibility with especial keenness. Whatever views may be entertained upon this subject by the parents or friends, it is plainly our imperative duty to put in requisition all the resources that art or ingenuity can suggest to preserve the life of the child, when its preservation is consistent with the safety of the mother. The opinion of some authors that a considerable proportion of the deaths occurring in these cases are caused by injury done to the spine, and particularly of the neck, is probably unfounded. It is certainly a severe, and we may hope an unjust imputation of ignorance and rudeness, that requires to be well-supported by facts. That it has occasionally occurred, particularly in the hands of rude and ignorant female practitioners, is undoubtedly true. I have recently seen a case in which I thought this to have been the fact, and I have always been of the opinion that too much caution could not be exercised to guard against an accident of this kind, which in the existing weak and relaxed condition of the muscles might happen from a very moderate degree of extension.

My reason for selecting this particular subject is, that as far as I have investigated it I have found in the books no sufficiently full and detailed directions for managing this class of labors, nor any full account of a manœuvre which I have practised for a number of years, by which I am confident that I have saved the lives of a considerable number of children that I should have lost by any other known procedure.

I was led to practise the manœuvre hereafter to be described by observing, by chance, that after the shoulders were expelled—could the head be brought into the most favorable position of which it was susceptible when in the pelvis—the child might breathe and even cry before the head was fully expelled.

Among the obstacles to the delivery of the head, endangering the life of the child, in these presentations, those most frequently met with and most important in the present connection, are a cessation of uterine contractions and unusual rigidity of the soft parts, both of which are liable to be present in the same case. Deformity of the pelvis, it is true, may be a more serious obstacle, but fortunately this complication is of rare occurrence. Where it does exist in a marked degree the child will almost certainly be lost.

While the head remains in the uterus the

stimulus of its presence keeps up the contractions, but where it has escaped from that organ and occupies the vagina, uterine contractions often entirely cease. In this situation the only forces brought to bear upon the head are the contractions of the coats of the vagina, and the forcing down of the uterus by the voluntary action of the diaphragm and other abdominal muscles. The former of these is very limited in amount, and the patient being exhausted and discouraged by long continued hard labor, and thinking, perhaps, that her task is finished, yields herself up to the indulgence of her comparative freedom from pain and withholds all voluntary aid. In this situation of affairs the physician is in a dilemma—extension to any considerable amount is inadmissible, the funis is almost certain to be compressed, pulsation is soon found to have ceased, the child twitches spasmodically, and the experienced accoucheur foresees the result.

Rigidity of the soft parts in a troublesome degree, as is well known, is most frequently met with in first labors, and more especially if the woman be somewhat advanced in life; and I may add that according to my observation it is more common among Irish than American women.

In order to manage with the best chances of success the presentations under consideration, I would suggest the following general plan, which is by no means claimed as original except in a few particulars.

*First.* All attempts at manual assistance, under ordinary circumstances, should be avoided until the os uteri is fully dilated, and the hips and even the shoulders are expelled by the natural forces.

*Secondly:* In making examinations great care should be taken not to rupture the membranes, as the nearer the labor is to being accomplished before this happens, the more successful is the result likely to be. Unfortunately, the membranes often rupture spontaneously in the early stage of the labor; sometimes they are ruptured accidentally in making an examination, and I have known them to be ruptured intentionally, with the view of ascertaining more precisely the presentation, and much trouble, including the death of the child, has been the consequence.

*Thirdly.* If there be great rigidity, bleeding, nausea, anodynes, pediluvia, fomentations to the pudenda or a hip bath, warm sudorific and relaxing drinks, the use of belladonna ointment and time, will be preferable to any manual assistance that can be rendered.

*NOTE.*—In modern days bleeding is so much out of fashion that it is rarely proposed, though formerly it was considered one of the safest and most reliable means of accomplishing this end. In the meantime, however, the use of anaesthetics has been introduced into obstetrical practice, and it must be admitted that they have claims to the highest rank in overcoming rigidity, alleviating the suffering, and shortening the pangs of child-birth. The effects of chloroform are often charming, but it is a treacherous agent, sometimes killing when danger is least suspected. It has not been my misfortune to kill any one with it, but I have seen effects from its use that have entirely deterred me from administering it by inhalation. From the use of ether, on the contrary, I have never witnessed any evil consequences, and in cases to which it is adapted, and when the amount of suffering is such as to demand it, I administer it freely and fearlessly.

During the last stage of the labor frequent draughts of cold water are often beneficial in stimulating the uterus to increased action, but the agent upon which the greatest reliance can be placed when the soft parts are in a favorable condition is ergot. When ergot is used, the choice of the time to administer it is important. Its full effects are desirable only during the last stage of the labor.

*Fourthly.* When the breech presents it is rarely, if ever, necessary, or even proper, to bring down the legs, and more especially in first labors, in which the gradual distention produced by the slow advancement of the breech is of the greatest importance in preparing the way for the head.

*Fifthly.* In regard to bringing down the arms, notwithstanding the high authority to the contrary, I am decidedly of the opinion that it should not be hastily done, or even under ordinary circumstances done at all, for the following reasons:—While they remain in the vagina and perhaps extend up into the neck of the uterus, the distention they occasion is the most natural and certain stimulus to expulsive action; and, by their position, they may in some measure protect the funis from compression. After the hips, with the legs folded upon the abdomen, have passed through the external parts, there can be no great difficulty in the passage of the shoulders and arms in almost any position they may chance to be, and the greater the distention of the external parts, and the greater the effort required to accomplish this part of the labor, the more readily will the head follow, so far, at least, as to descend into the pelvis, where it can be successfully managed.

*Sixthly.* The most favorable position of the head after the expulsion of the shoulders is with the face inclining posteriorly, and when delivery is effected by turning and in aiding the child along in the presentations under consideration, this position should be favored by acting upon the body and shoulders, and also by passing the left

hand or a finger or two up upon the head, when practicable, and making pressure in a direction to favor this position.

We will now suppose the head to be in the pelvis, the face inclining backward into the hollow of the sacrum, the shoulders and arms liberated, the funis compressed, but the child still alive, the pains inefficient, the woman discouraged; there is great anxiety about the life of the child, and we have not our forceps at hand; what shall we do?

Under these circumstances the body of the child should be carried directly forward between the thighs of the mother, until it forms a right angle with the long axis of the pelvis, or even until its back is nearly in contact with the abdomen of the mother, and be supported in this position with the right hand, or, if the labor be not immediately finished, by an assistant. In the meantime, one or two fingers of the left hand should be passed so as to reach the chin or a higher portion of the face, which should be gently depressed and brought down, and at the same time, if necessary, the occiput may be pushed upward by the fingers of the right hand in such a manner as to give the head a quarter turn on its own axis, and bring the mouth and nose directly to the vulva. This manœuvre can usually be accomplished with great facility, especially if favored by a pain or a little voluntary aid of the mother in forcing down the uterus. In order to be successful, however, this evolution must be performed with dexterity and not with force, and should not be attempted until the head has descended or is descending into the hollow of the sacrum; as to separate the chin too early from the breast deranges the natural process of labor, and while the head is high up the body should be kept in a line with the axis of the pelvis, and should be gently swayed from side to side or backward and forward to excite the womb to action, and the chin, when it can be reached, be depressed upon the breast. The uterus should in the meantime be gently compressed and kneaded, with the view of exciting action. When the head has been brought into the position described, the mouth and nose presenting at the vulva, the child, if not asphyxiated or too much exhausted, can breathe freely, and will sometimes attempt to cry many minutes before the head is expelled, and with a little attention to keeping the labia separated and the perineum pressed backward, its chances of life are for a sufficient length of time nearly as great as after complete delivery. The most

favorable position of the woman is on the left side, a little inclining towards the back. The thighs should be widely separated, and the right one supported by an assistant.

The idea of admitting air to the child before the head was delivered was suggested many years ago. The plan proposed was to keep the perineum pressed back and to introduce a female catheter for the admission of air to the nose or mouth of the child, and I recollect being highly gratified with the occasional success of this plan, but I became convinced by observation that the success depended entirely upon the situation of the head. If low down, and the face situated posteriorly, by separating the labia and pressing back the perineum, sufficient air will sometimes be admitted to enable the child to catch its breath. The catheter is of little use. While the body of the child is nearly in a line with that of the mother, the face is so shut in by the perineum and the closure of the vagina, that to supply it with air is an awkward business; besides, when this can be done the operation above described can more easily be performed, and success will be much more certain. When the face is forward—a somewhat rare occurrence—the body of the child should of course be carried backward, when the same object will be attained. With the view of expediting the delivery of the head the vectis or forceps can often be used with great advantage, and the position into which the head is brought by this manœuvre is the most favorable position possible for the operation. The body is held entirely out of the way, and instruments can be applied with great facility and in a moment's time. We are cautioned by authors to guard well the perineum, as though this was the most important duty of the physician; but it seems to me that it is of secondary importance when compared with the life of the child, and especially as it is presumable that after the shoulders, perhaps with the arms up, have passed, the head will follow with but very little danger of this accident. I am aware that it does sometimes happen under the most careful management, but it is probably of rare occurrence in these presentations, and whether it does or does not happen will depend more upon the time taken up in the delivery and the consequent condition of the organs, than upon anything that can be done by protecting the perineum with the hand. Aside from all considerations in reference to the life of the child, I am confident that this is the easiest and most expeditious method of delivering the head. It requires the least possible room,

is the most favorable for the application of instruments, and, whether the child is in danger or not, is the method I usually pursue. It is, perhaps, unnecessary to remark that the manœuvre here recommended has no application to those cases in which the head is detained at the superior strait—a class of cases much more difficult to manage, and attended with much more danger to the child.

The utility and frequent applicability of the plan above imperfectly described might be illustrated by the relation of a very considerable number of cases, in one of which the child absolutely cried before the head was born; but as this paper is perhaps already too long, I shall relate one only.

On the 27th of February, 1851, I was called to see a Mrs. G., an American woman, aged 27 years, who was in labor with her first child at term. She had been married nine years, during which time she had miscarried six times in the early months without much trouble, except that on one occasion she had profuse hæmorrhage, on which occasion only I had attended her. She had been in labor about two hours when I arrived and learned that the membranes had ruptured previous to the commencement of the pains. On examination I found the inferior or pelvic extremity of the body and one foot presenting. The arms, genital organs, and os coccygis of a female child could be distinctly made out, and the situation of the foot indicated that the knee was drawn up upon the abdomen. The os uteri was not fully dilated, but there was no evidence of extreme rigidity, and as the pains were efficient and the process of labor going on naturally, I did nothing of importance except to watch its progress. In less than an hour the os uteri was fully dilated, and the inferior part of the body and foot presented at the vulva and were soon expelled. The other leg was flexed upon the abdomen as is usual in breech presentations. The shoulders, with the arms up over the head, soon followed, and, as the child was not large and the external parts apparently not very rigid, I apprehended no delay in the expulsion of the head. As soon, however, as the head had escaped from the uterus, the pains in a great measure ceased, and what few there were seemed to produce no impression upon the child. I found also that the external parts were more unyielding than I had supposed, and that the funis had ceased to pulsate. By performing the evolution above described the face was made to present at the vulva, when the

child at once began to breathe, and made a feeble attempt to cry. Air was freely admitted to the face by separating the labia, and a quantity of bloody mucus which seemed to obstruct the breathing was wiped away. The woman was urged to aid such pains as she had as much as possible, and an assistant was directed gently to grasp and compress the uterus. In this situation of affairs I waited several minutes, rendering such assistance as I could, expecting momentarily that the head would be expelled. Being disappointed, however, in my expectations, I sent her husband for my forceps, which were in my chaise standing near the house. The child being held by an assistant, one branch was passed over the head and used as a vectis. In this manner the delivery was soon effected. The child was alive and strong, and the mother had a favorable recovery. As nearly as I could judge, five or six minutes elapsed after the child began to breathe and made an attempt to cry, before the head was delivered.

In one case, to which allusion has been made, and which occurred a number of years before, the child breathed and cried stoutly nearly or quite double that length of time. The woman lying on her back, the child was supported in a perpendicular position, standing, as it were, upon its head. On that occasion I had not my forceps with me.

Having spoken of the use of instruments in this class of cases, I would remark that I have lost a considerable number of children by not having them at hand, and I have so often regretted this occurrence that I now make it a point to be always provided with short forceps or a vectis. The forceps is evidently preferable, as both branches may be necessary, while one branch answers the purpose of a vectis perfectly well.

In conclusion, I would remark that others may have understood the directions given by authors differently, and may have practised this or a better method; but it has seemed to me that there were no sufficiently particular directions for the management of this class of cases to enable the inexperienced to manage them with confidence and the greatest attainable success.

If the perusal of this paper should suggest to the mind of the practitioner a single new and practical idea, that may save the life of an individual or serve the cause of humanity, the ends of the writer will have been answered.

## A CASE OF INTESTINAL CALCULUS.

Translated for the Journal from the *Wien. med. Wochenschr.*, by A. H. N.

The patient was 31 years old, of a robust constitution, and perfectly healthy till he arrived at the age of 16.

From his 6th till his 14th year he was employed each summer in the fields guarding cattle, and during this time his principal articles of food were bread, cherries and sorrel.

At the beginning of his 16th year, he began to suffer from frequent attacks of nausea, vomiting and constipation, for which he received medical treatment, and the symptoms disappeared in a measure, so that he was able to resume out-door work.

In the course of six months nausea and vomiting again came on, the latter being accompanied by intense cutting pains in the umbilical region. He again applied to a physician, and in the course of two or three weeks was partially relieved, so that he was able to go into the fields, though not entirely free from abdominal pains.

From his 17th till his 30th year patient continued to work, suffering at irregular intervals in the manner above described, and seeking medical advice every three or four months, when pain was unusually severe. During this entire period his diet was limited to milk, soft-boiled eggs and barley-gruel. The use of meat, pastry or beer was followed invariably by severe pain, vomiting and constipation.

On the 29th of September, 1866, his condition having become no longer supportable, he abandoned work, returned to his parents, and summoned the assistance of Dr. Aberle, by whom this case is reported. Patient was found in bed with the following symptoms:—

He complained especially of obstinate vomiting and severe pain in abdomen, accompanied by great prostration. The pain in abdomen was of a sharp, cutting character, and came on every ten or fifteen minutes, causing him to cry aloud. The abdomen was found to be greatly distended, especially in the ileo-cæcal region, and vicinity of ascending colon. Upon the right side, the abdomen was quite tender upon pressure; upon the left side, however, no pain whatever was experienced, not even when strong pressure was applied.

A more careful examination of the ileo-cæcal region disclosed a tumor about the size of a turnip, above which a smaller tumor could be felt about one-half the size of the other. Both tumors presented an ir-

regular surface, and were exceedingly painful upon pressure; the patient would not admit, however, that the cutting pains had been particularly severe in their vicinity.

At this point it occurred to Dr. Aberle that a case had been reported by Cruveilhier, where 615 cherry-stones were found in the large intestine. Considering, then, the history of this patient, and remembering that, from his 6th to his 14th year, cherries had formed a large portion of his food during the summer, it seemed possible that the tumors here found might be caused by collections of encrusted cherry-stones. This conclusion seemed the more justifiable when the very irregular surface presented by the tumors was considered, and the fact that intestinal concretions are found usually in the large intestine, and cause pain in the entire abdomen. Patient was therefore immediately bled; poultices were applied to abdomen; enemata of oil were given, together with morphine to allay the pain. After this treatment had been followed for several days, the pain and vomiting ceased, and patient was able to leave his bed. The tumors, however, were found not to have diminished in size. As he continued to improve, a strong drastic cathartic was next given, with the hope of breaking up and expelling the concretions. This occasioned severe colic and was rejected. It was noticed soon after this, however, that the tumors had changed their relative position, which tended to confirm the diagnosis already made. As drastic cathartics could not be given, a persistent use of enemata and castor-oil was made, until at the expiration of a year (June, 1867) a stone was evacuated weighing about two ounces.

Upon the seven days immediately succeeding, one stone was passed each morning, and subsequently two to four each day, so that in the course of two or three weeks the patient had been relieved of thirty-two stones, weighing in all above three pounds. In the centre of each of these calculi was found a cherry-stone, increased to so great a size by the substances deposited around it. After the evacuation of these stones the tumors in the ileo-cæcal region disappeared entirely, and the patient has since enjoyed most excellent health.

A chemical analysis of the stones showed them to be composed as follows:—

Inorganic substances	{ Phosphate of lime.
	{ Phosphate of magnesia.
	{ Sulphate of lime.
Organic substances	{ Considerable fat.
	{ Animal lime.
	{ Traces of cholesterine.

The following analysis has been made (in another case) of a calculus which had formed around a plum-stone:—

Water . . . . .	22.5
Substances extracted by alcohol and ether . . . . .	.3
Other organic substances . . . . .	11.3
Phosphate of lime . . . . .	60.5
Phosphate of magnesia . . . . .	4.3
Sulphate of lime . . . . .	1.1

100.0

The above shows the composition of the outer layer, which differs but slightly from that of the inner, as will be seen from the analysis of the layer immediately surrounding the plum-stone, given below:—

Water . . . . .	17.5
Organic substances . . . . .	9.2
Inorganic substances . . . . .	73.3

100.0

The coloring matter, which is undoubtedly identical with that of the feces, was slight, so that even the darkest layers, when pulverized, were but little discolored.

Intestinal calculi are usually small, seldom exceeding in size a hazel-nut, although in rare cases they have been known to attain the size of an apple.—(Förster, vol. ii. p. 153.) They lie imbedded in a fold of the intestine, or in the vermiform appendix, covered with mucus, and although at times their existence may not be suspected during life, they more frequently cause irritation, inflammation, and even ulceration of the mucous membrane. When analyzed, they are found to be composed principally of carbonate or phosphate of lime, and phosphate of ammonia and magnesia, deposited around a fruit-stone or other foreign body.

Fürstenburg has divided intestinal calculi into four classes.

1. *True Intestinal Calculi*.—These are found only in horses, are of a grey or brown color, and have been known to attain the enormous weight of 20 pounds. They are composed principally of phosphate of ammonia and magnesia.

2. *False Intestinal Calculi*.—These are foreign bodies, or concretions, around which deposits of phosphate of ammonia and magnesia have been formed, making their outward appearance identical with that of true calculi.

3. Concretions consisting of a mass of hair, vegetable fibres and various salts; they have a porous structure and an ash-grey or brown color. They are found in the large intestine of horses and swine, and in both

the stomach and large intestine of dogs and ruminating animals.

4. *Hair-balls* (*Ægagropili*).—These are frequently met with in the intestines of animals, and are sometimes found encased in a shell or coating composed of various salts, which gives them a firm, smooth outer surface.—(*Magaz. f. d. ges. Th'rh'lk.*)

## Reports of Medical Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.  
CHARLES D. HOMANS, M.D., SECRETARY.

JAN. 25th.—*Fever—Typhoid?*—in a Patient 69 Years of Age; Death Forty-sixth Day.—Dr. CORTING reported the case.

B. A., aged 69; master mechanic; in affluent circumstances; a large, muscular man, 6 feet 1 inch in height, and weighing 190 to 200 pounds. Cellulo-fatty development considerable; of somewhat Esau-like tendency; habits remarkably regular; uniformly from youth strictly temperate; disposition cheerful, mild and rather retiring; hitherto always healthy, having a large, high, airy, detached, well-ventilated and well-drained residence; became ill about the 1st of December, 1868. Complained of some discomfort in bowels, with a sense of tightness over the abdomen. Thought he would "starve it out," and took only light food for several days. A few days later, took cathartic pills; and these not proving satisfactory, repeated the dose Dec. 10th. Called medical advice two days later.

At that time, Dec. 12th, he was about house, suffering from sensations of weakness only. His pulse was slightly accelerated, being 80, or, at times, a little more. Tongue slightly coated, whitish. Breath very fetid. Skin, heat, &c., not remarkable. Went to his chamber in afternoon.

For some days after this he continued to sit up most, if not all, of the day; was quiet, or dozing a greater part of the time. At night slept well without dreams or confusion. Jan. 1st to 2d, it is recorded "sleep quiet as an infant's."

From Dec. 15th to 18th (third week of illness), had a troublesome headache, which increased on lying down, so that he spent most of two nights in the chair. This then passed off, and he had no more of it, or of any other pain, during the whole of his sickness.

He took to his bed early in the fifth week, and generally retained a dorsal pos-

ture. No bed sores. He invariably affirmed that he was comfortable, and felt no cause of inaction, except weakness. His mind was clear, his intellect generally active; though apparently unaware of his peril to the last. Though often drowsy, he was always easily roused. At times there was some slight slowness of comprehension, but no delirium until the last few hours, and no unconsciousness until he was moribund. *Never any jaclitation or subullus.*

At the first of his illness he did not have chills or sensible increase of temperature; but as the disease progressed several chills occurred (the first Dec. 27th, the last Jan. 14th), generally light, and succeeded by increased but not excessive heat. The severest, which took place January 3d, was followed by such extreme prostration that for several hours he was thought to be in a dying condition.

The pulse, for the first half of the sickness, rarely exceeded 90. After each chill, it continued higher than before. In the last weeks it rose to 100 (Jan. 2d), then 120 (Jan. 4th), and finally, in the last days, to 150, and even more.

The respirations, ranging from 24 to 28 during the middle of the disease, became over 30 (Jan. 4th), for several days were 48, and for the last two days were 60 a minute.

The tongue, from having a thin, whitish coat, became foul, dark, stiff, cracked, and exceedingly troublesome, for these reasons, especially in the last days. There was a proportional amount of sordes on teeth and gums.

Rose spots, though sought for, were never found. Sudamina, not numerous, however, were noticed Dec. 29th, and a few days later. Neither epistaxis nor other hæmorrhage occurred at any time.

The bowels were occasionally distended with gas, and never entirely free from it. A frequent annoyance from this source had been experienced during health. There was never discovered, though often sought for, any tenderness in the iliac region, nor in any other part of the abdomen. From Dec. 13th to 16th, had loose, dark-colored dejections, apparently prolonged effects of the cathartic pills. After this, he required enemata to move the bowels, and the dejections were solid and normal to the last.

In the third week of his sickness his urine was very high colored, and left behind a thick, red deposit in the vessel. Afterwards, it had a normal appearance. Examination in fourth week of illness, by heat

and acid, gave no results. Dec. 29th (fifth week of illness), analysis gave spec. grav. 1012, a trace of albumen, excess of urea—otherwise normal. Jan. 7th (sixth week of illness), analysis gave specific gravity 1008; otherwise normal. Urine was always abundant, and during the latter part of the time was passed into an urinal without rising from the bed.

Though for a few days in the early part of the sickness, about the time of the purgation, there was a slight jaundiced hue in the skin and eyes, the liver gave no other evidence of disturbance, though most diligently examined. The spleen could not be felt.

The sounds of the heart were always normal.

The action of the chest was natural, without râles, or cough, until the last few days. After the prostration of the night of Jan. 3d, from which he never fully rallied, the respiration became gradually more and more labored and oppressed, accompanied with rattle, and coarse râles all over the front. The back could not be examined during the last week. During the last day or two breathing was short, noisy and jerking.

Jan. 4th, in consultation with Dr. Buckingham, a thorough examination was had, especially of the extremities. The legs and feet were moved at will, naturally. There was no swelling, or tenderness, or want of sensibility in them. The same may be said of his arms and hands.

Two days later (three days after the severe chill), the left leg began to swell, and became œdematous. This increased rapidly, till the whole limb was tense; and motionless, apparently through weight and stiffness. No tenderness could be found in any part of it. There was no pain in the limb. Two or three days before death the swelling subsided, and masses could be felt in the ham, and (the day before death) along the course of the great vessels. Jan. 8th the right hand had become puffed, and so stiff that the fingers could not be closed. This entirely passed off three or four days later.

From the commencement of the disease there was loss of appetite, and he generally took the allowance brought to him rather from a sense of duty than from any desire for food. He gradually rejected gruels, broths, &c., and asked for wine and other stimulants. The effect of these was always very satisfactory to the patient, and flattering to friends. For the last two weeks, or more, he lived almost entirely on various forms and compounds of alcohol. Jan 2d

he asked for ale, and piteously begged for more when attendants were disposed to limit the quantity. As an indication of nature's cravings in this direction, which were followed rather than anticipated, the amount taken in twenty-four hours, as recorded for Jan. 6th to 7th, may be instanced. It consisted of one pint and a half of brandy, one pint and a half of old Madeira wine, one tumbler (half pint) of milk punch strong with St. Croix rum, one tumbler of wine whey, three bottles (pints) of ale, three pints of water to dilute the wine and brandy; and three teaspoonfuls of beef tea, tried at three different times and repelled with apparent disgust after each single spoonful.

Death took place, without struggle, Jan. 18th, 1869.

Although the disease is not usual at such advanced age, and in this instance had many perplexing peculiarities, yet by a review of daily notes kept during its progress (of which the foregoing account is a resumé) the diagnosis from the first of typhoid fever appears to be sustained. The autopsy, as follows, made by Dr. John Homans, gives it additional confirmation:—

"A portion of the lower part of the upper lobe of the right lung about four inches in diameter was solidified, of a red color, friable and cedematous. Two small abscesses, about the size of peas, just beneath the pleura, such as are found in cases of pyæmia, were seen in the lower edge of the lower lobe of the left lung.

"In the ileum, at about two and a half inches from the ileo-cæcal valve, was an irregular ulcer, two inches by one inch, penetrating to the muscular coat. Whether it occupied a Peyer's patch could not be certainly determined; the long axis of the ulcer was parallel to that of the bowel. A second ulcer was seen one inch above the first, circular in shape, and not so deep. The mesenteric glands and spleen were normal. The left external iliac and femoral veins were filled with red, partially diffluent, grumous clot; the foot, ankle, leg and thigh were cedematous."

Dr. Jackson, who had examined the specimen when first removed, said the ulceration was opposite the mesentery, and that in one extremity there was some appearance as of a Peyer's patch that was not ulcerated, but it was very equivocal. There was also dilatation of the vessels of the sub-peritoneal cellular tissue, as is often seen in typhoid cases. Ulcers, resulting from acute disease, and unconnected with typhoid, but seldom occur in this part of the intestine. The spleen was normal in Dr. C.'s case; but

it often subsides after the second week if it has been enlarged. Typhoid fever is certainly a disease of the comparatively young, but he well remembered that Dr. Jas. Jackson used to speak of its occasional occurrence in old persons.

*Feb. 8.—Typhoid Fever after Middle-age; Peyer's Patches.* Dr. COTTING, in relation to the case reported by him above, said that, according to the books, the age of the patient was against the diagnosis, but that the general symptoms during life and the autopsy justified it. Aitken, in his work on "The Science and Practice of Medicine,"\* one of the last but not the least, says old persons cannot have typhoid fever, only in exceptional cases, as Peyer's patches disappear after the age of 45-50. The following is Dr. Aitken's statement:—

"This lesion in the ileum is especially recognized as the 'anatomical sign' of enteric or typhoid fever. It is necessary to remember, however, in connection with the age of typhoid-fever patients, that the solitary vesicles and the aggregate glands of Peyer are known to be most fully developed and most active in youth, up to the age of early manhood; after that time they begin to disappear, and are obviously less active in the adult after thirty years of age. Structure and function seem to be alike impaired by age, till at length, after forty or forty-five years, traces only of their existence are apparent, or they have altogether disappeared. The gland substance (whose structure has been so well described by Dr. Allen Thompson, Kölliker, and Bochni) no longer exists; and the places where the patches of Peyer once were, may be detected only after careful examination—a mark of varied form and character being all that indicates the place of the patch. There is, therefore, a good anatomical reason why typhoid lesions are rarely found after fifty years of age, and seldom after forty. Dr. Jenner records only three cases beyond fifty—namely, one at fifty-one and two at fifty-five. Dr. Wood has observed one case at fifty-five years of age. Dr. Murchison notes two cases above sixty-five, and refers to five other cases between 60 and 75, related by MM. Lombard and Gendron. Dr. Wilks refers to the case of a woman, aged 70, of very doubtful history (Path. Society, 1861). These exceptional cases are explicable when it is known that the existence and functional activity of these glands are sometimes prolonged for an indefinite term of years beyond the usual period of

\* The Science and Practice of Medicine, by Wm. Aitken, M.D. Edin. p. 375.

their existence. On the other hand, it is in childhood and early life that these glands are most obvious, and their functional activity the greatest; and therefore it is extremely significant to find that 'more than one half of the cases of typhoid fever occur between 15 and 25 years of age; and in very early life the proportion of cases of typhoid would be greater were it not that many children laboring under this disease are described as cases of 'Infantile Remittent Fever'' (Murchison).

Dr. Cotting added that he had sought for authority for the statement of Aitken, but had been unable to find any. None of the works on anatomy, general or pathological, at hand, contained any intimation that Peyer's patches disappeared in the later periods of life; nor was there, so far as he could find, any allusion to such disappearance in other treatises on Theory and Practice. The morbid anatomists he had applied to were not aware of any facts to support the statement. In Kölliker's Human Histology, Vol. II., p. 102, is a plate described in a foot-note as a "Portion of a Peyer's patch of an old man," which was the only reference to the subject he had seen. This was not figured as an exception, and there is nothing in the context to show that it was an uncommon thing to find Peyer's patches in old men. Aitken makes his statement as though the disappearance was an established and well-known fact. "The gland substance," he says, "no longer exists." Is his great work to be judged by this specimen of it?

Dr. Jackson said he had seen cases where there was no appearance of these patches, but he did not remember the ages of the subjects. He had examined a man 44 years of age, who died of typhoid fever, with perforation of one of the ulcerated patches.

Dr. Hodges said Peyer's patches vary in form, number and dimension; frequently, instead of being elongated, they are round, and if of small size may seem of doubtful identity. He had never seen or heard before this evening that they are not found after a certain age; they belong entirely to the mucous coat, and might be swept away by disease; formerly they were regarded as pathological by some writers, but now they are universally considered to be normal. He had never thought of ascribing to age their absence or diminution in size. For purposes of demonstration, or in the dissecting room, he did not recollect having been unable to find them. He alluded to a fatal case of poisoning by antimony, in which attention was attracted

to the strongly marked Peyer's patches and the appearance of ulceration they presented. The specimen was shown by Dr. Jackson, in 1848.

Dr. Jackson said that he had long ago remarked that the patches frequently vary from their typical form. They may be circular instead of elliptical, and quite small; and he had prepared a specimen for the College Museum to show this fact. If typhoid fever occurs, these patches will probably be diseased; and then the mistake will very naturally be made of supposing that there is disease, and, it may be, ulceration in the mucous membrane as well as in the patches. Well-attested cases of a second occurrence of typhoid fever in the same individual have been observed. And it would be curious to see if in such there would be disease in the patches, but higher up than usually found; the patches below having been previously destroyed. In reference to Dr. Cotting's case, the ulceration was certainly the result of acute disease; and such disease, and particularly ulceration, is rarely seen in the lower part of the ileum, except in cases of typhoid fever. Peyer's patches he had never seen acutely inflamed in adults, except in fever; but in a child that died of acute dysentery, and in a very severe form, he had seen them coated with lymph, as well as the mucous membrane of the large intestine; and he had recently seen the same appearance in a little child three years old that had died of acute follicular enteritis. In the exanthemata of children and in croup the patches are said to be sometimes inflamed. Redness he had seen several times in such cases, but nothing more; and he was inclined to doubt its pathological importance. Dr. J. alluded to the redness of the patches that he had observed in persons who had died whilst the process of digestion was going on, and in whom there was no reason to suppose that the appearance was in any way the result of disease. These cases occurred between twenty-five and thirty years ago, and have been fully referred to in the published Catalogue of the Society's Museum. He had never, however, seen any confirmation by others of this observation.

At a meeting of the New York Pathological Society, Dr. Lewis Smith exhibited the appendix vermiformis removed from a mulatto child, two years old, who died of broncho-pneumonia. The specimen was interesting on account of its extreme length, six inches.—*N. Y. Medical Record.*

# Medical and Surgical Journal.

BOSTON: THURSDAY, APRIL 22, 1869.

WE cheerfully accord considerable space for the paper of Dr. H. K. Oliver, read at the last meeting of the Society for Medical Improvement.

MR. EDITOR, —I beg your insertion of the following remarks made before the Boston Society for Medical Improvement concerning the comments of Dr. J. B. S. Jackson upon a clinical lecture by Prof. Oppolzer. Yours truly,

HENRY K. OLIVER, JR.

At the meeting of this Society on the 8th ult., Dr. J. B. S. Jackson offered some comments upon the clinical lecture on "Ulcus Rotundum Ventriculi" by Prof. Oppolzer, of Vienna, which appeared, translated by Dr. Lincoln, in the Boston Medical and Surgical Journal for March 4th. Under other circumstances—had, for example, the comments been offered by a gentleman less distinguished than Dr. Jackson, or had a difference of experience, simply, been submitted by him, it would not have been worth while to take up the time of the Society by again referring to the subject. But the case is otherwise. Dr. J. is a person of authority in the profession, and he has, in submitting his remarks, made strong suggestions of the incompetency of Prof. Oppolzer as a clinical teacher. Moreover, the comments have appeared in a public medical Journal, accompanied by advice to young men which signifies, virtually, "wherever you go in pursuit of your medical studies, avoid the wards of Prof. Oppolzer. He is a man of indecent ideas; he is, moreover, not to be relied upon as an accurate teacher."

There are many young men in this city who, at some period in the past twelve years, have listened with pleasure and, as they supposed, with profit to the teachings of Prof. Oppolzer. They feel that injustice has been done him, and they ask for a hearing in his behalf.

I will take it for granted that the translated report of the lecture in the Medical Journal, is, as far as it goes, a correct one, and will now ask permission of the Society to examine the objections put forward by Dr. Jackson.

In some of his comments upon the lecture, Dr. J. seems to me to have made much of trivial points, and in others to have misinterpreted the idea intended to be conveyed, while in others he seems to disagree, not with Oppolzer alone, but with many writers of acknowledged reputation.

Of the points which seem to be of little moment, the first is that of the selection of a title of the affection. Oppolzer uses the terms "Ulcus Rotundum Ventriculi" and "Perforating Ulcer." They did not, however, originate with him. Rokitsky employs the term "Perforating Ulcer," as does also Abercrombie. "Ulcus Rotundum" is used by Müller. Cruveilhier prefers "Simple Ulcer" and "Chronic Ulcer." All these names are more or less appropriate, and yet an objection to each is made by Brinton. Dr. Jackson,

while giving, in his published comments, an excellent reason for calling the affection "Round Ulcer\*," favors no name but "Chronic Ulcer." But the ulcer is not always chronic. Rokitsky says,† "This process may run an acute course; though it is commonly chronic."

Cruveilhier, who, if I am not in error, first suggested the name "Simple, Chronic Ulcer," intimates more than once that the lesion may run an acute course. He says, for example:—"It is evident that the acute ulcer is much more likely to induce this perforation than the chronic ulcer, which latter is almost always followed by protecting adhesions."

Brinton§ says that "its progress is sometimes so rapid as to penetrate the stomach and destroy life in a few days."

See also Chambers.||

In regard to the use of Latin by Oppolzer, which is so strongly criticized by Dr. Jackson, we can hardly believe the latter gentleman to be really serious. The Latin has been and is now the language of science—the universal language. Until within a comparatively short time all the lectures in the Medical School of Vienna were delivered in Latin; and now, the prognoses by the bedside are almost always given in this language. Do we not all of us employ the Latin constantly? Do we not say tinnitus aurium, fistula in ano, delirium tremens, angina pectoris, &c. &c.? Are we not taught hundreds of technical terms in human anatomy, from Calvaria over Pons Varolii to Os Calcis? And do we not all write prescriptions in Latin, good and bad?

Dr. Jackson thinks the term "bits of ice" is better than "pills of ice." I had almost determined to pass over this objection as being really too trivial to dwell upon, but as Dr. J. has thought it worth while to make inquiry of the translator of the lecture with regard to this particular point, I may be pardoned for alluding to it. "Eispillen" is a term in not infrequent use in the Vienna Hospital, and means something more than "small bits of ice." It includes, namely, a suggestion as to the method of administration. The connection in which it is used by Oppolzer shows of itself that he intended that the ice should not simply be held in the mouth but be swallowed. He therefore says "the best remedy is Eispillen," which, since we do not commonly use the term "pills of ice" in English, might be better translated by a phrase such as the following:—"The best remedy is bits of ice, small enough to be swallowed whole." The use of this term "Eispillen" is strictly in accordance with the genius of the German language, in which an idea which we should express by a phrase is expressed by a single, though complex, word.

The next objection of, as it seems to me, trivial importance, is to the use of the term "Magistery of Bismuth." This is "nothing more

\* "The ulcer is by no means always round, though it is sometimes remarkably so, and always tends more or less to that form."

§ Digestion and its Derangements, p. 362.

than the substrate," and it may be found by reference to the index in the United States Dispensatory, a work of much later date than the "old days of alchemy."\*

In other portions of the <sup>1</sup>ecture criticized by Dr. Jackson, he has evidently misapprehended the idea which Oppolzer intended to convey. In one instance, also, Dr. J. has, in quoting from the translation, inadvertently added a comma in such a position that the meaning is thereby obscured.

First, the word "continuous" is alluded to as being a very mild term to express the character of the pain in case of perforation. But Oppolzer is not speaking of the severity of the pain in such cases, in either of the two places in which he uses the word. He simply calls attention to the fact of its unmitigating character as a symptom of perforation and peritonitis.

Dr. J. also misinterprets Oppolzer's idea when referring to the use of "conche preparata." The latter mentions the composition of this remedy in such a way as not only not to encourage, but virtually to interdict its employment.

I next come to the subject of the excrement of dogs, with regard to which Dr. Jackson speaks with so much feeling; and I must be allowed to say that I cannot conceive how a careful reader could fail to appreciate, as Dr. J. has, the meaning of Oppolzer here. "(Dog's dung has been employed for the same purpose.)" This is simply a matter of history; and there is not the slightest intimation that Oppolzer ever used dog's dung, or that he advises its use. To make it, moreover, quite clear that the reference to this substance was a matter apart from the main current of his remarks, the reporter enclosed it in parentheses, the purpose of which Dr. J. most unaccountably—I had almost said uncharitably—suggests can be for no other purpose than to cover up the indecent idea which he attributes to Oppolzer.

Within the memory of more than one member of this Society, human urine mixed with molasses was frequently prescribed by the most esteemed physicians of a neighboring city, as a remedy for croup, and that without throwing over it the "mantle of a foreign language." This fact was mentioned some time ago at a meeting of the Society for Med. Observation, by a late Prof. of Clinical Medicine, but not one of those present imagined for a moment that he was accustomed to employ such a mixture in his own practice.

The sentence which Dr. Jackson has copied incorrectly is the following: "The nutrition is often but slightly affected, provided there is no hæmorrhage and cardialgia does not set in during the night." In the transcription Dr. J. has inserted a comma after the word hæmorrhage. The clause, as read correctly then, is easily understood, or if not, it is abundantly explained by the sentence which follows it.

As regards the points in which Dr. Jackson differs from Oppolzer, and in differing from him differs from well known authorities, the first is concerning the size of the stomach. Dr. J. has never found anything remarkable about the size of the organ in round ulcer, excepting in one case.

\* A friend has suggested the fact that we sometimes speak of saturnine colic, aqua regia, elixir opii, &c., and, quite often, of lunar caustic.

Cruveilhier,\* in speaking of contraction of the pylorus as affecting the capacity of the stomach, says, "The contraction of the pylorus is divided into two classes; in one there is enormous dilatation of the stomach; . . . I have cited elsewhere a case in which contraction was the result of the cicatrix of a circular ulcer which occupied the pylorus."

Rokitansky† says:—"Contractions or stenoses are the result . . . of cicatrization after ulcerative destruction of the tissue at this" (pylorus) "and at other points." "In common stenosis of the pylorus it (dilatation) is mainly developed at the splenic portion; it equally reaches an enormous degree, and proves fatal at last by paralysis."‡

Brinton§ speaks of the local dilatation of different parts of the stomach from local failure of muscular contraction, from the destruction of the tissue by the ulcer.

Chambers|| says that in thirteen cases of dilated stomach at St. George Hospital, two had chronic ulcer.

See also Foerster and Reynolds, and others.

As regards the diminution of the size of the stomach, Rokitansky says: "A diminution of the stomach is sometimes produced as a permanent condition in consequence of an insufficient supply of nutriment; in other cases it is the consequence of textural disease, especially that produced by cicatrization of extensive ulcers.

And again, "when the ulcerative process has involved the muscular coat . . . a union (may be) gradually effected. We find then corded cicatrices which shorten the stomach in its transverse diameter."¶ . . . "

Brinton\*\* says:—"Where the previous loss of substance has been considerable, this process" (of cicatrization) "often seriously affects the shape and capacity of the stomach."

See also Foerster and Habershon.

Dr. Jackson has never seen the slightest appearance of an hour-glass contraction of the stomach to which Oppolzer refers. I make the following quotations:—

Rokitansky,†† in speaking of "congenital malformations of the stomach, in which an annular contraction divides it into a cardiac and a pyloric stomach," says:—"Similar and various other malformations are observed as acquired conditions; they have their origin mainly in loss of substance and in cicatrization of the so-called perforating gastric ulcer."

Budd‡‡ says:—"When the ulcer is large and situated across the lesser curvature of the stomach, the process of healing, by the contraction that attends it, often permanently alters the shape of the stomach, diminishing its breadth at that part. This change of shape is very striking in these two preparations from the King's College Museum, in each one of which the stomach is divided into two pouches, as if by a string passed transversely round it, looping up the greater curvature towards the lesser."

\* Op. cit., liv. xii. p. 2.

† Pathological Anatomy (Sydenham Society), vol. ii.

p. 22. ‡ Ibid., p. 22. § Op. cit., pp. 22 & 23.

|| Lectures, p. 505, note. ¶ Op. cit., p. 23.

\*\* Op. cit., p. 32. †† Op. cit., p. 21.

‡‡ On the Organic and Functional Diseases of the Stomach, p. 115.

Brinton, continuing the remarks above noted with reference to cicatrization, says:—"In such instances the cicatrix corresponds to a constriction of the organ, which gives it more or less of an hour-glass shape. And in extreme cases the contraction amounts to an absolute stricture which impedes the transit of food, and thus gradually causes great hypertrophy and dilatation of the over-distended segments of the stomach behind the obstruction."

See also Foerster, Habershon, Heschl and Bennett.

Dr. Jackson remarks:—"Oppolzer speaks of the continual contraction of the organ as the ulcer extends;" and adds, "but in ulcers of the largest size, I have seen nothing of the kind." Dr. J. does not here give the exact language of the translation, which reads, "The stomach is diminished in size, when the ulcer is extending and yet continually contracting."

Cruveilhier\* says:—"It is not uncommon to find ulcers of the stomach completely cicatrized, except at a single point, where the ulcerative process still goes on and ends by perforation." And again, "Perforation may occur; . . . after cicatrization, and it may in such a case be the result, first, of a fresh ulceration which is established at the very bottom of the cicatrix or at a point in its circumference, . . ."

To the remark of Oppolzer that catarrh relaxes the muscular fibres and thereby gives rise to dilatation, Dr. Jackson opposes the statement that the mucous membrane is generally quite healthy.

Rokitansky† says:—"There is no further morbid appearance beyond a thickening of the parietes in the immediate neighborhood of the ulcer, and a tumefaction of the gastric mucous membrane." And again,‡ whilst we find the tolerably uniform irritation within, giving rise to hypertrophy of the mucous membrane. . . . And again,§ "It (the ulcer) is invariably accompanied by chronic catarrh and hemorrhage of the gastric mucous membrane: . . ."

Budd|| says:—"Chronic inflammation of the kind we are now considering sometimes results . . . when the pyloric orifice is slightly strictured . . . the stomach cannot always completely empty itself, and what remains in it, after digestion is over, frets and inflames its mucous coat."

Brinton,¶ in speaking of localized dilatation, says:—"It seems not improbable that in all of them the accumulation of the gastric contents, which form the immediate cause of the dilatation, and thickening of the coats of the stomach," &c.

Abercrombie\*\* divides the ulcer of the stomach into three classes, in two of which he says the mucous membrane is healthy, while in the third it is generally diseased.

See also Reynolds, Foerster, Habershon.

There seems to be little doubt that the coats of the stomach are apparently healthy in some cases, while it is quite unlikely that Rokitansky would

make such statements as I have quoted without his experience justified him in so doing.

The next objection is to Oppolzer's statement of the combination of *ulcus rotundum ventriculi*, and chronic maladies of the stomach in general, with tuberculosis pulmonum and phthisis. In this phrase the translator has omitted\* the word "schliesslich," which means here "in the end." The sentence with this restitution will read:—"Most cases of *ulcus rotundum ventriculi*, like chronic maladies of the stomach in general, are, in the end, combined with tuberculosis pulmonum and phthisis."

Langston Parker† says:—"We shall observe, however, in pursuing our investigations, that these forms of pulmonary irritation" (as results of gastric affections), "if continued, soon degenerate into one of the forms of inflammation I have alluded to, and are, in some instances, followed by phthisis, of which Andral, De Larroque and myself have reported examples."

Parker, also, in speaking of one of Louis's cases of phthisis, says:—"In this case it certainly appears that the disease in the chest may in the first instance be produced by the gastric irritation, which terminated in ulceration of the coats of the stomach."

One of the conclusions Parker arrives at is ‡:—"Inflammatory irritations of the digestive organs are readily, under certain circumstances, transmitted to the lungs, where they may become the source of various diseases, as cough and disordered respiration, bronchitis, pneumonia, hæmoptysis, and even tubercular phthisis."

Brinton states that out of twenty cases of his own four had phthisis, and adds:§—"The gastric ulcer is not unfrequently accompanied by pulmonary disease. . . ."

And again||:—"Lastly, as regards the complications of the gastric ulcer with diseases of other organs, the best information which I have been able to collect is derived from the writings of Jaksch, Dittrich, and Engle. Comparing the statements of these observers, which refer to a total of some hundreds of cases of the lesion, we find them all agreeing as to the frequency with which the ulcer is associated with pulmonary tubercle. This complication appears to be present in about nineteen or twenty per cent. of the whole number of ulcers."

Brinton, however, does not seem inclined to think that even the above percentage is large enough to prove any immediate connection between the two affections, and adds¶:—"These complications seem to indicate what indeed there is little difficulty in supposing—that this long and exhausting malady predisposes the constitution to a variety of other diseases; . . ." This is probably the view Oppolzer takes of this point, judging from his use of the word "schliesslich."

\* In case of perforation Oppolzer states that

\* Omitted purposely, as Dr. Lincoln informs me, having been considered superfluous in the translation. After reflection, Dr. L. agrees with me that the position of the word gives it a different signification from that which, at first sight, it seemed to have.

the liver is pressed back by the air in the peritoneal cavity, and that there is consequently a resonance on percussion in the region of that organ." Dr. Jackson does not remember seeing such a displacement in any dissection, nor has he heard any reported here, and adds:—"The peritoneum is not distended by rupture of the stomach, as the pleura is by rupture of the lungs." I remark, in the first place, that Oppolzer does not say that the displacement of the liver may be seen on dissection; he is referring to the appearances which may be noticed immediately after the accident of perforation. It would hardly be expected that the liver would remain pressed out of place after the cause of such displacement—the air in the peritoneal cavity—was allowed to escape by the section of the abdominal walls. With regard to the possibility of the escape of air from the stomach which Dr. J. doubts, I would remark that, considering the fact that a development of gas in the stomach in the disease of this organ under consideration is not uncommon, it would not be surprising if, when perforation ensued, some of it should escape into the cavity along with the other contents of the stomach; especially if the rupture were occasioned by external violence, or by the effort of vomiting. The amount of air thus escaping, however, would seldom cause much distention, and would probably escape observation by any means of investigation except that mentioned by Oppolzer, namely, percussion of the right hypochondrium. That such a condition of things as is stated by Oppolzer may actually exist, in opposition to the belief of Dr. Jackson, I call attention to the following:—Dr. Charrier reported a case\* of perforation into the peritoneum, observed in a lady who had presented, for a certain length of time, gastric symptoms of an indefinite character. There were two perforations which were the result, without doubt, of two ulcers more or less old. *The depression of the liver and its separation from the diaphragm was noticed, due to the sudden escape of gas into the peritoneum.*

Dr. Jackson objects to the use, by Oppolzer, of the term "necrosis" as applied to the death of soft tissues. This use of the word is, however, quite common in Germany, and is sometimes met with in other than German authors.

Rokitansky, on page 159, vol. i., heads a section thus:—"GANGRENE, NECROSIS," and commences the section as follows:—"Like normal textures, new formations of every kind, tumors, exudates, pus—are liable to become necrosed. Fluids degenerate through necrosis to gangrenous ichor. . . ."

Piorry speaks of "Necrosie péritonique. Gangrene du péritoine." (Nysten.)

It is also used in English: "Necrosis Cerealis—Ergotism—Morbus Cerealis." The gangrene sometimes following the use of ergot. (Dun-glison.)

Some points in regard to the treatment, which Dr. Jackson thinks is certainly remarkable, have already been noticed by me. One or two other criticisms are made, the first of which is of the use of belladonna. "This," says Dr. J., "is probably given with a view to relax the muscular coat of the intestine, but we should hardly like to

give enough of the drug to produce such a marked constitutional effect, when we have so many perfectly safe laxatives at our command." To this I reply, that there is no reason to suppose, from the words of Oppolzer, that the drug is given as a laxative, and, second, that when used with this view belladonna is a perfectly safe drug. First, Oppolzer says:—"Give bismuth with morphia, or, if the patient is inclined to be constipated, with belladonna." That is to say, when the patient is inclined to be constipated, give instead of an anodyne which will aggravate the constipation, like morphia, one like belladonna, which will not constipate. But granted, secondly, that Oppolzer recommends the belladonna in order to move the bowels. This property it has confessedly, and it produces its effect in this regard without exciting any dangerous symptoms.

Stillé\* says:—"Trousseau declares belladonna to be the remedy, *par excellence*, for habitual constipation. It does not purge nor produce loose stools, but only renders defecation easier."

"Cases illustrative of the efficacy of this treatment are reported by Fiessinger,† by Blache,‡ and by Fleury.§

"A similar approbation of the medicine is expressed by Leared,|| by Wilson Fox,¶ and by Fleming."

I will also quote from Wood's Therapeutics and Pharmacology, p. 800, under the head of Belladonna:—"In the internal neuralgic affections of the abdomen, as gastralgia, enteralgia, nephralgia, &c., the external use of the medicine should be resorted to when the complaint is complicated with vomiting or purging, while opium is used internally. But, in the contrary condition of constipation, it would be better to try the effects of extract of belladonna internally."

Finally, Dr. Jackson objects to the employment of local bleeding and cold application to the epigastrium in perforation, as being useless and as tending to the patient's discomfort, and therefore cruel. Dr. J. would, however, allow active treatment to be employed if there is the slightest chance for the patient under such circumstances.

I reply, first, perforation of the stomach is not invariably fatal.

Habershon\*\*—"Where perforation has taken place, and the symptoms of peritonitis suddenly produced, there is a slight chance that life even then may be prolonged."

Bennett††—"Many cases are on record of evident perforations of the stomach, which have been cured by judicious treatment; . . . such perforations have a great tendency to become re-closed by the rapid formation of fibrous lymph round their edges."

Valleix‡‡—"Finally, and it is the observations of Delpsch which furnish us with this very interesting information, we see that perforation of the

†† Commentary on case, p. 446.

‡‡ Vol. ii. p. 573.

\* Quoted in Valleix, vol. ii. p. 569.

stomach need not be immediately fatal, even when it takes place into the peritoneal cavity."

Wood\*—"Under any plan of treatment, the case must be considered as almost desperate; but the one described affords some little chance of a favorable issue."

Brinton†—"In other instances, the effusion of the gastric contents is confined to the immediate neighborhood of the perforated spot. . . . In other instances, the portion of peritoneal cavity circumscribed by the inflammation continues to suppurate, and is thus gradually converted into a chronic abscess, which finally discharges its contents at some point or other of its exterior. There are about twenty cases of this kind on record."

2d. Local bleeding is recommended by several writers in perforation of the stomach.

Wood‡—"Peritonitis dependent upon perforation of the alimentary canal, or other cavity, requires a somewhat peculiar treatment. Depletion may be pushed as far as the strength of the patient will permit."

In the case of recovery alluded to by Bennett, leeches were applied to the abdomen, and Cruveilhier§, in a record of a case to which he was called, says:—"I diagnosticate a perforation of the stomach (15 leeches, cataplasms to the abdomen)."

Valleix|| in speaking of the treatment of peritonitis as a consequence of perforation, says:—" . . . leeches are to be employed as in the preceding affection, taking the precaution to graduate these means to the condition of the (vital) forces of the patients."

Other writers include the treatment of perforation in that of peritonitis from other causes, recommending pretty generally bleeding, and, as a rule, say nothing of making peritonitis from perforation an exception. Stokes, however, remarks that in most of these accidents the powers of life sink so rapidly that bleeding, either local or general, cannot be attempted.

3d. Concerning the employment of cold applications to the epigastrium.

Copland¶ says, under the head of the treatment of peritonitis:—"It was advised by the late Dr. Sutton, of Greenwich, and by some German physicians, to apply cold or evaporating lotions, or ice, to the abdomen in peritonitis." Copland prefers warm applications, but adds:—"Dr. Symonds, however, remarks that, in some cases, cold evaporating lotions have seemed preferable to other applications, the evaporation being accelerated by blowing the surface with a common bellows. 'The relief,' he adds, 'has been most striking, even when the disease was too far advanced for a cure.'"

I will simply add that the employment of cold in some affections is far more common in Vienna than here. We are, for example, a little disinclined to apply cold to the joints in acute rheumatism; but, in Vienna, this is the chief means of treatment of this affection, and I do not remember to have seen any cardiac or other complication result from it.

This finishes what I have to say of the special points of Oppolzer's lecture which have been

commented upon by Dr. Jackson. But I beg the patience of the members of the Society for a short time longer.

In a previous volume\* of the Boston Medical and Surgical Journal, there is a report of a lecture on "Ulcus Rotundum," by Prof. Oppolzer, communicated to the Journal by Dr. J. C. White, immediately after his return from Vienna. This report, as I understand from Dr. White, was made up from his own notes of Prof. O.'s lecture. I purpose quoting one or two portions of this report.

"It (Ulcus Rotundum) often occurs in tuberculosis, though there is no connection between them."

"Sometimes it affects the pyloric orifice itself, and no food can pass into the intestine. The abdomen sinks, the stomach is distended even below the umbilicus, and unless the pylorus dilates again, marasmus carries the patient 'to the ground,' as the Germans say. Enlargement of the organ takes place in the case above mentioned, on account of paralysis of its muscles, induced by the collection of fluid in its cavity. Enlargement may also be caused by the chronic catarrh which generally accompanies the ulcer, and in this case we shall have the usual symptoms of dyspepsia. The stomach has been so much enlarged as to simulate pregnancy, and has been punctured for ascites. . . . An ulcer may, on the other hand, cause contraction of the organ by its cicatrix, or of the pylorus, as in cancer."

"Oppolzer gave him pills of chopped raw veal. . . ."

"If constipation contra-indicates the use of opium, we must substitute extract of belladonna."

"Ice pills given often, &c."

"If chronic catarrh and enlargement of the organ are present, we must direct our treatment to the former. . . . The mucous membrane of the stomach is usually thickened and covered with a dense, pale mucus, which does not allow the gastric juice to come in contact with the food. . . ."

In closing the report Dr. White remarks:—"From the frequent occurrence of this disease in Vienna, I am inclined to think that many of our cases of 'dyspepsia' might be resolved into the same, were we not so easily satisfied and blinded by that very unsatisfactory word."

On page 329, of the same volume, there is another lecture of Prof. Oppolzer, "On the Therapeutics of Diseases of the Stomach," translated from the "*Zeitschrift der k. k. Gesellschaft der Aerzte zu Wien*," by Algernon Coolidge, M.D. From this lecture I will make a few quotations.

"I have often seen good effects from local bleeding, in . . . ulcers producing inflammation in their neighborhood, or in the diaphragm. But local bleeding I used only in strong persons and when great tenderness existed."

"I have often with good success employed heat and cold."

"In ulcers of the stomach I preferred opium to its tinctures. In persons suffering at the same time from obstinate constipation, I was obliged to resort to belladonna or conium."

"In danger of perforation of the stomach, the

\* Op cit., 5th ed., p. 174.

† Op. cit., 6th ed., p. 856.

‡ Vol. iii. p. 331.

† Op. cit., p. 173.

§ Liv. xv. p. 2.

¶ Dict. Pract. Med.

\* Vol. lvii. p. 269.

best agent is opium, which stops peristaltic motion, thereby favoring the chance of adhesion."

"In ulcers of the stomach of any kind, I always prefer the carbonates of the earths to those of the alkalies, because they irritate less the surface of the ulcers."

"Vegetable charcoal is useful . . . As common wood coal generally contains splinters, which cause irritation, it is best to use coal made of burnt bread."

I call particular attention to the remarks concerning the use of opium, and to the avoidance of irritating substances.

To return to the lecture which is the subject of Dr. Jackson's comments, and to the fact that important points do not receive mention therein, one has only to know that less than fifteen minutes is required to read the lecture in the original, in a deliberate manner, and to be informed that Oppolzer spends from an hour to two hours by the bedside of a single patient, to be convinced that a very full report has not been given.

Finding, as I have, that Dr. Jackson's experience in the round ulcer has differed from so many authorities, it has occurred to me that the opportunities for observing the disease might not be so good in this country as in Europe. Dr. J., for instance, has only seen two or three times a cicatrix that he thought might be caused by the healing of a chronic ulcer. He admits, however, that cicatrization is remarked upon by authors as sufficiently common.

Brinton\* says:—"The healing of such ulcers by a process of cicatrization, appears to be far more frequent than is generally supposed. The examinations of Dittrich, Jaksch, Willigk and Dahlrup reveal a total of 147 scars, and 156 ulcers, making the proportion of the former nearly equal to that of the latter." Brinton does not hesitate to admit the statements of these observers, and adds:—"In favor of these results we may point out, how easily cicatrices of small size might escape discovery, in less careful scrutinies of the mucous membrane of the stomach than those made by these excellent observers."

Rokitansky†:—"A cure may result at any of the stages, as proved by the various cicatrices frequently observed on the inner surface of the stomach."

See also Reynolds, Valleix, Foerster, Heschl and Bennett.

No one will question Dr. Jackson's faculty of observation, and there is no alternative but to accept the conclusion that the affection is comparatively rare in this country. I quote from Dr. Wood on this point. Dr. W.‡ says, in speaking of the percentage of the frequency of the simple ulcer of the stomach, given by Brinton:—"This is certainly much beyond anything to be met with in the United States. During more than 25 years in which I was physician of the Pennsylvania Hospital, I did not meet with one fatal case of simple ulcer of the stomach; and my colleague, the late Dr. Pepper, assured me that his experience corresponded with my own. Nor did I see, in the same institution, more than four cases in which the symptoms authorized the inference that they might

proceed from simple ulcer of the stomach; and of these, two at least were in foreigners. In private practice, moreover, instances of the kind are extremely rare. The difference can be ascribed only to the mode of living. . . ."

In conclusion, if the writers whom I have referred to in this paper are to be relied upon, I think I am justified in saying that the evidence of Prof. Oppolzer's incompetency as a clinical teacher is not sufficient to warrant the advice to young men so publicly given by Dr. Jackson. If the latter gentleman is right in his opinion, by all means let the fact be widely known, for a teacher with such a decided and extraordinary faculty of commanding attention and of imparting information as Prof. O. is a very dangerous person if his matter is not accurate.

I did not intend at this time to attempt any eulogy of Oppolzer, but I cannot forbear, before closing, to mention a remark made by Dr. Bowditch after his return from Europe a few years ago. On my asking him how he liked Prof. Oppolzer, he replied, with earnestness, that he certainly was the finest clinical lecturer he had ever listened to; but he immediately qualified his remark—if it can be called qualifying—by adding, "I don't know; Louis, in his prime, was perhaps his equal."

And again, in a letter from Vienna to the *London Medical Times and Gazette* of May 19th, 1860, may be read the following:—"The most frequented clinic is, with justice, that of Prof. Oppolzer. . . . Before all things is his teaching rich for the investigation of disease; and so exact and conscientious an analytical diagnosis is nowhere else to be met with. He is the very model of a clinical teacher. . . ."

(At the completion of the reading of this paper, Dr. Jackson remarked that he still stood by the statement of his experience as recorded in the article published by him. The writer desires to say that no question is raised as to the reliance upon this record. The friends of Prof. Oppolzer simply ask that respect may also be paid to the statement of his experience.)

WE trust the JOURNAL readers will endorse the wisdom of giving the preceding article at length and without abbreviation of the references to authorities. It is not merely that this course was the most respectful toward the distinguished names whose conflicting experience was cited; but we have now had brought together forms and placed on record the clinical observation of some of the lights of the medical world, in a manner which is instructive in the highest degree. The conflict of experience here set forth is no new thing under the sun. For instance, in former days it was the fashion to refer everything to "Louis's laws," just as it was the custom for the "Faculty" of a preceding generation to carry gold-headed canes. As the stethoscope song has it:—

"Said he—the man must die you see,  
By the fifty-seventh of Louis's laws."

Now one of those dicta was that tubercle chiefly affected the left infra-clavicular space. Observa-

\* Op. cit., p. 163.

† Op. cit., p. 31.

‡ Op. cit., 6th ed., p. 636.

tion in this country did not confirm that statement. In a word, statistics which appear at first sight abundant to superfluity, are sometimes found, on comparison with other collections of facts, to be not sufficiently comprehensive.

**OZONE TEST FOR BLOOD STAINS.**—The *Lancet* of March 30th speaks of the ozone test for blood-stains (the action of the coloring matter of the blood upon the resin of gnaiaum in the presence of autozone) as a new color test for blood. That Journal represents this test to have been discovered in Australia, and to have been recently approved by an English chemist. We are informed by excellent authority that the *Lancet* is in error here; that the test was discovered by Van Deen in Germany; and that it was used in the investigations conducted in this city with reference to the murder of the Joyce children, as long ago as the summer of 1865. It formed also, as we are apprized, a part of the evidence offered by the Government in the recent trial of Andrews at Kingston.

**DR. BROWN-SEQUARD.**—In relation to the communication made by Dr. Brown-Séquard at the preceding session of the Imperial Academy, that gentleman, at the meeting of the 23d of March, was interrogated by several of his colleagues, as to what part of the restiform body he cut or irritated in order to produce the dry gangrene and sanguineous effusions he had described.\* He replied that his point of election was the end of the *calamus scriptorius*. Section of a very few of the fibres was sufficient. Nothing was easier, he said, than to expose the restiform bodies, and to irritate or cut them. He further remarked that certain peculiar conditions were a sure index that the experimental lesion had really affected the part of the restiform body indicated. These were paralysis of the tongue and anaesthesia of the lips, from which resulted dropping of food introduced into the mouth; the hypoglossal and trifacial nerves arising in the neighborhood of the *calamus scriptorius*. The Professor again pointed out the analogy which exists in a very great number of instances, between the symptoms experimentally induced in animals, and those revealed by clinical observation in man.

**PROSTITUTION IN CHINA.**—The *Union Médicale* has an article translated from the German, describing prostitution in China. The evil exists to an enormous extent in the cities of the Celestial Empire. The dwellings where the traffic is carried on are hardly "houses of ill fame." So far from their being kept shady they are made conspicuous by blue window shades, whence they are called

"blue houses." At night the curtains are raised in the front windows, the reception apartments rendered brilliant with lights, and the building resonant with what is called music. Their patrons enter day and night without concealment. The prostitutes are entirely in the power of the proprietors of these establishments, and are often sold, when children of a dozen or more years, to be trained up to their miserable occupation. When no longer serviceable these creatures are often turned off to wear out their existence in the streets, picking up a meagre pittance by mending garments and sundry menial offices.

As a concomitant of the social evil in China the most unbridled obscenity of language prevails in books and in the family circle, the presence of children placing no check upon it.

As a consequence of this state of things, venereal disease is rife and in a virulent form; but is said to be worst among women frequented by Europeans. The Chinese accordingly avoid those women whose traffic is among foreigners, to whom they endeavor to leave the inferior article.

**PARALYSIS FOLLOWING THE USE OF CHLOROFORM.**—At the session of the k. k. Gesellsch. d. Aerzte, Vienna, Feb. 19, there was reported a case in which the patient became completely aphonic and aphasic after awaking from the slight degree of narcosis required for the removal of a tooth. There was also at that time considerable spasm of the glottis, most marked during inspiration. The loss of voice and speech continued during five weeks; but for three weeks past the patient has been able to speak in a low voice. The treatment up to the date of report was mainly by electricity; the constant stream is found most useful. Dr. Hofnobl, who reported the case, believes that the symptoms were due to cerebral apoplexy, caused by the chloroform narcosis. The patient was a perfectly healthy woman, a cook, aged 22, and never had hysteria.—*Wochenbl. d. k. k. Ges. d. A. in W., Mar. 3.*

D. F. L.

**AMERICAN MEDICAL ASSOCIATION—CORRESPONDENCE OF DRS. BALDWIN AND NOTT.**—We have received printed copies of a lengthy letter addressed by Dr. W. O. Baldwin, of Montgomery, Alabama, to Dr. J. C. Nott, formerly of Mobile, now of New York; and of one from Dr. Nott, in reply to Dr. Baldwin. The purport of these letters is to deprecate any coolness on the part of Southern medical men toward the American Medical Association, during its approaching session at New Orleans. Dr. Baldwin says:—

"You may have seen some little dissatisfaction expressed in newspapers over a *nom de plume* indicating the author to be a physician, but I assure you such sentiments are confined to but very few, and have failed to reach the great heart of the profession. I was grieved, however, to see even this manifestation of opposition to the great repre-

\* Vide Journal of April 15th.

sentative interests of the medical profession of this country. It has no root and can bear no fruit in science or general beneficence.

"This dissatisfaction grew out of the action of the Association at its meeting in 1864, in relation to a preamble and resolutions introduced by Dr. A. K. Gardiner, of New York. These were, in fact, a remonstrance against the war ethics of the Government, and, in substance, provided that the President of the United States, heads of departments and members of the United States Senate be requested by the Association to 'take such action as shall cause all medicines and medical and surgical instruments and appliances to be excluded from the list *called contraband of war.*' The action taken on these resolutions by the Association was to lay them on the table indefinitely, and which, in parliamentary parlance, I believe, means that it was 'not desirable to consider them at that time.'

"I assume, then, the broad ground that it was a question with which the Association had nothing whatever to do, and one which was not properly before it for discussion; and, it seems to me, that it was expecting too much of our Northern brothers to suppose that they, at a time when all the sinews of war were called most vigorously into execution, would place themselves in antagonism to their government upon a question which was entirely outside of their *professional position and accredited duties.* In doing so, they certainly would have been transcending their legitimate sphere and meddling with the prerogatives of those to whom the regulation of the ethics of war had been assigned and who claimed exclusive jurisdiction over the question.

"Pardon me, dear doctor, for trespassing so long upon your valuable time. I know that you will excuse it in the interest you feel in the general prosperity of the medical profession of the whole country, and especially in the desire which you feel to see your Southern friends come fully up to their duty, in meeting the honorable advances which have been made by our Northern brothers, looking to a complete and perfect fraternization. I think the American Medical Association is to be the power through which a greater good is to be accomplished for the profession in this country, than has yet been achieved. On this point you may perhaps hear from me at some future time. I will only say now, that its organization had its inception chiefly in an idea which has not yet been realized—that of elevating the standard of medical education in this country. But I believe its labors in this direction will yet be felt and acknowledged. To this end, it *must be national* and represent the interests of the profession in every part of the country. Those who comprehend the grandeur of its germ, appreciate full well the ultimate possibility of its nature, and will see to it that the inspiration which gave it birth shall be worked to a final and successful end. The advancement of science, the affections of an enlightened brotherhood, the interests of society and the good of humanity are, all united with it, and from every section I have the most gratifying assurances of a determination to bury all other sentiments in the one great purpose of promoting harmony and concert of action, with the kindest

feelings of fraternal regard. Assure our friends of the North of this, and tell them we desire to meet them in large numbers in New Orleans in May.

"With assurances of the highest regard, believe me, dear doctor, most sincerely and truly your friend,  
W. O. BALDWIN, M.D."

In Dr. Nott's reply occurs the following passage:

"Now, sir, I beg leave to say a word of my personal experience, since the war, at the North. Soon after the war closed, I was summoned to Washington as a witness in the Wirz trial, and seized the occasion to run over to Philadelphia to see what I could discover that was new, in the way of books, instruments, practice, &c.; we having been shut out from the world for four years. Not only did the medical gentlemen of Philadelphia receive me politely, but they seemed to feel as if they thought I might feel some delicacy in presenting my rebel face in their midst, and were more desirous than I had ever seen them of treating me with hospitality.

"About a year ago I came to pitch my tent in the city of New York, determined to ask no favors of the members of the profession, and not one of them can say that I ever solicited an introduction to him; and yet it would sound like egotism were I to tell of half the respect, the hospitality and kindness I have received, both in and out of the profession, in the city of New York. It is but justice to the faculty in New York to say that in tone, talent and attainment, it will compare favorably with that of the large capitals of Europe."

*Comments of the St. Louis Medical Reporter.*—With reference to the letters of Drs. Baldwin and Nott, the *St. Louis Medical Reporter* says:—

"On reading these letters the thought has arisen in our mind that if the party now in power were only actuated by the spirit of genuine patriotism and true Christian charity which glows in the utterances of Drs. Baldwin and Nott, instead of by feelings of hatred, malevolence and revenge, how soon the wounds inflicted on the body politic by the late civil war would be healed, and the Union established on the sure basis of enduring friendship and mutual affection. We hope that the Association will set an example in this respect which may even yet reach the hard and obdurate heart of politicians. Let the motto be: 'The union and harmony of the profession for the sake of the Union, for the good of humanity.'"

On page 108 of the same number of the *Reporter* is the following passage:—

"*Negro and Female Medical Students.*—We see it stated in the *New York Medical Gazette* that the faculty of the Massachusetts Medical College having left it to the students to decide whether negro men and white women should be matriculated, they decided to admit the former and reject the latter. Perhaps if the women had blacked their faces they might have fared better."

Notwithstanding that the old volcano still gives an occasional rumble, we have no doubt that the association will be kindly received in New Orleans; and we think the selection of that city for the

meeting this year well-timed. Social attrition will do much toward smoothing some of the rough corners. But political allusions had better be altogether eschewed.

WHAT IS "PROTOPLASM?"—By Dr. LIONEL S. BEALE, F.R.S. It will be remarked that in the lecture referred to in the *Medical Times and Gazette* of March 6, Professor Huxley includes under the term "protoplasm" matter in very different states, and maintains that this "protoplasm" is the physical basis of *life*, or the basis of physical *life*.

1. Living moving matter, as that in the cells of *vallisneria*, the hairs of the nettle, the matter of an amoeba, a white blood-corpuscle, and a pus corpuscle, is protoplasm.

2. Contracting matter—as of muscle, which is capable of shortening or lengthening (contraction, relaxation), but not of moving in any direction like the amoeba and the white blood-corpuscle, &c.—is protoplasm.

3. Albuminous matter, as white of egg, which is not capable of any movement at all, is protoplasm.

4. Dead and roasted matter is protoplasm. "Mutton contained protoplasm of the same nature as was found in every living thing." "As he spoke he was wasting his stock of protoplasm, but he had the power of making it up again by drawing upon the protoplasm of some other animal—say of a sheep. (Laughter)."

If a white blood-corpuscle, a piece of muscle, white of egg, and roast mutton are all to be called *protoplasm*, surely the name may be also employed in speaking of hair, horn, nail, bone, wood, coral, and shell, and a number of other things; indeed, we might call men, animals, and plants, dead or alive, *protoplasms*. Huxley makes no difference between dead and living and roasted matter, and he confuses together the living thing, the stuff upon which it feeds, and the things formed by it, or which result from its death.

If the *forms* assumed by water are due to the properties of its constituent gases, it must be admitted that these forms are not quite so numerous as those taken up by protoplasm, and that the greater number of elements in the latter substance will not account for the difference. It is quite true we cannot ascertain by physical investigation any difference between the protoplasm of the embryo of a worm, dog, and man, and I have myself dwelt upon this, but it by no means follows that the *properties* of protoplasm to form worm, sheep, bird, man, as the case may be, are due to the arrangement and nature of its component molecules, of which Dr. Huxley knows nothing definite. Of course any one might assert that the differences exhibited by the fully formed "protoplasms" of these living things are to be explained by supposing a gradual alteration in property and arrangement of the elements as growth advances, but it would be absurd to attribute these alterations to physical changes, because there is no instance of non-living matter undergoing such alterations in property. Mr. Huxley teaches *unity of power*, and it was therefore unnecessary for him, at least in the city of Hume, to defend himself against the

charge of teaching materialism, which could not with reason be made. Dr. Huxley manifests a tendency to modify his old views and to bring them more in accordance with the results of researches made during the last ten years. Already the vacuoles of his periplastic substance have become tenanted by the simple or nucleated protoplasms, and he may yet discover that the latter existed before the former, and that, after all, the endoplasm is really of more importance than he was disposed to think. From this the transition to the opinion that the periplastic matter is formed by the protoplasm, which possesses power of a remarkable kind, will be simple and easy enough.—*Medical Times and Gazette*.

THIRD DENTITION. By J. K. DODGE, West Eau Claire, Wis.—Two cases of third dentition have lately come to my notice, which may be of interest to the profession. One was that of a lady of 48 years, who had her teeth taken out eight months since, and who now has a right superior cuspid erupting, and I think there are signs of others. The second case was that of a daughter of the first, aged 18, who had her teeth taken out some six months since; a right superior cuspid appeared, which I extracted. These are interesting cases, happening the same to both mother and daughter.—*Dental Cosmos*.

THIRD DENTITION.—Dr. H. H. Nelles, dentist, reports in the *Canada Journal of Dental Science*, the case of a lady forty-five years of age, from whom he extracted a number of roots preparatory to the insertion of a full set of artificial dentures. Upon a second visit, to his surprise, he found that nature had sent forth a well developed superior *cuspidatus*. In anticipation that nature would complete the work thus auspiciously begun, Dr. Nelles deferred inserting an artificial set of teeth. This case brings to mind a fact related of himself, by a gentleman of our acquaintance. When he was 19 years of age, his four upper incisors were broken off by a blow with an iron bar. The roots were extracted but no artificial teeth inserted. Some months after, while at the table eating, he was greatly startled to discover the points of teeth projecting through the gum. The incisors soon fully supplied the place of the lost second teeth, and are as perfect in every particular as one could wish.—HENRY GIBBONS, JR., M.D. *Pacific Med. and Surg. Jour.*

ANOTHER SPECIMEN OF WESTERN BABIES.—Detroit has entered the lists in competition with her sister cities and villages of the West, and promises to be not far behind any of them in giving to the world infants of Brobdignagian proportions.

On the 19th of February, Mrs. J. W., 43 Sibley Street, was delivered of a well-formed male infant 24½ inches long, weighing 16 pounds *in puris naturalibus*. The forceps were brought into requisition in effecting the delivery, the mother being rather under-sized, although a well proportioned woman. Her weight, in fact, *after parturition*, is stated as only 92 lbs.—*Detroit Review of Medicine and Pharmacy*.

## Medical Miscellany.

**AMERICAN MEDICAL ASSOCIATION.**—Delegates to the meeting of the American Medical Association at New Orleans who pay full fare thither can be returned free on the certificate of the Permanent Secretary, by the New Haven, Hartford and Springfield Rail Road and by the Providence, Hartford and Fishkill Rail Road, provided that on the latter road the delegates present their certificates to the Superintendent at the depot in Hartford. Certificates good during the month of May.

B. H. CATLIN, M.D.,  
Committee for Connecticut.

**DEPARTURE OF DR. E. H. CLARKE FOR EUROPE.**—Dr. Edward H. Clarke has left for a sojourn of several months in Paris. His absence will be regretted by a large circle of patients and friends. A few days before he sailed, we persuaded him to lend us the manuscript of his address to the Graduating Class at the recent Commencement of the Medical College; and we propose occasionally to make from it certain extracts.

**DEATH OF DR. ALEXANDER H. STEVENS.**—At a special meeting of the New York Academy of Medicine, held April 2d, 1869, for the purpose of paying a tribute to the memory of the late Alexander H. Stevens, M.D., a series of resolutions were unanimously passed, expressive of the high estimation in which he was held by the members of the Academy, and of their deep sorrow at his departure.

**CASES OF ALLEGED TRANCE.**—We presume that most of the cases of alleged trance in young girls which are prolonged for weeks or months, and said to be attended with abstinence from food, may be diagnosed as hysteria with surreptitious nourishment. One of these cases is now on the *tapis* in the English Medical Journals.

A NOVELTY in journalism is the announcement of a bi-monthly *Journal of Parasitology*, to be published under the direction of Prof. Hallier, of Jena. Parasites of man, of animals, and of plants are to be described; and authors of all countries will be allowed to write for the periodical in their vernacular. A literary Babel!

At a recent meeting of the New York Pathological Society, Dr. Noyes exhibited a cutaneous horn, five eighths of an inch in length, removed from the edge of the upper tarsus of the left eyelid of a young man aged eighteen. On the top of this growth was a single eyelash. Although no microscopical examination of it had been made, he supposed that it consisted merely of an aggregation of epithelial scales. He considered it a very rare form of disease, but as often happened, a parallel one had just been reported in a late number of the Boston Medical and Surgical Journal.—*N. Y. Medical Record*.

**CEREBRO-SPINAL FEVER.**—We regret to hear that this fatal disease has made its appearance in Dundalk, Ireland, and has proved fatal in many instances. Dundalk has always been remarkable for its salubrity.—*British Medical Journal*.

**ANTIDOTE TO CARBOLIC ACID.**—Messrs. Calvert wish to make known the fact that sweet-oil or castor-oil in large quantity is the best antidote to carbolic acid, when it has been swallowed in poisonous doses.—*Medical Times and Gazette*.

**DR. WM. PEPPER**, in a paper on Phosphorus Poisoning, says:—"It appears to us, then, that phosphorus acts as so many other poisons do, by entering the blood in the form of a highly irritant substance, and in the course of its excretion from the various glands, induces a degree of irritation bordering on inflammation, attended with a proliferation of cells, which, as frequently happens, are not fully organized, and readily undergo fatty degeneration."—*Am. Jour. of Med. Sciences*.

**PRURITUS VULVE.**—It is stated (*Gazette des Hôpitaux*, Jan. 7th, 1869) that this annoying affection is often entirely cured and always diminished by a lotion consisting of five parts of corrosive sublimate dissolved in fifty parts of alcohol. A teaspoonful of this solution is to be diluted with a pint of tepid water, and applied as a wash to the parts several times in the day.—*Ibid*.

### NEURASTHENIA, OR NERVOUS EXHAUSTION.

By GEORGE BEARD, M.D., Lecturer on Nervous Diseases in the University of New York.

I AM to speak to-night of a condition of the system that is, perhaps, more frequently than any other, in our time at least, the cause and effect of disease.

I refer to *neurasthenia*, or exhaustion of the nervous system.

The morbid condition or state expressed by this term has long been recognized, and, to a certain degree, understood, but the special name *neurasthenia* is now, I believe, for the first time presented to the profession.

It is quite recently, indeed, that the phrase nervous exhaustion has been popularized, at least as a term expressive of any special condition of the system. Prof. Austin Flint, in his Treatise on the "*Principles and Practice of Medicine*," devotes a brief space to this subject, and acknowledges his indebtedness to Dr. Fordyce Barker for first suggesting the phrase "*neurasthenia*" as expressive of a special morbid condition. Besides this brief notice of Prof. Flint, this important condition of the nervous system has not, so far as I know, been dignified by a separate heading, or distinct chapter in any of our most approved treatises on the Practice of Medicine, although the general phrase "*nervous exhaustion*" quite frequently occurs in conversation and medical literature, and is now the common property of the profession.

My own attention was called to this morbid condition quite early in my professional life, and in the cultivation of the department of Neurology and Electro-therapeutics, I have enjoyed excellent opportunities both for the study and the treatment of all the various grades and phases of this frequent malady. As a matter of necessity in describing, recording and studying cases of nervous disease, I have for some time been

in the habit of employing the term *neurasthenia* to express the morbid state that is commonly indicated by the indefinite phrase nervous exhaustion.

This nomenclature would seem to be justified by philological analogy, by scientific convenience, and by actual necessity.

The derivation of the term *neurasthenia* is sufficiently obvious. It comes from the Greek *νευρον*, "a nerve," *a*, privative, and *σθενος*, "strength;" and, therefore, being literally interpreted signifies want of strength in the nerve.

The character of this malady, if I be allowed to call it such, may best be understood by comparing and contrasting it with *anæmia*, a condition which has been more thoroughly discussed, and is therefore more vividly appreciated by the profession at large.

*Anæmia* (derived from *a*, privative, *αἷμα*, euphonic, and *αἷμα*, "blood") is to the vascular system what *neurasthenia* is to the nervous. The one means want of blood; the other, want of nervous force.

Both *anæmia* and *neurasthenia* may be the effects of acute or chronic diseases, and both may be either acute or chronic in their course. Thus *neurasthenia* may be the effect of wasting fevers, exhausting wounds, parturition, protracted confinement, dyspepsia, plithisis, morbus Brightii and so forth. *Anæmia*, as is well known, may result from the same diseases.

Both *anæmia* and *neurasthenia* may also be the cause of chronic and acute diseases. Thus *neurasthenia*, or nervous exhaustion, may give rise to dyspepsia, headaches, paralysis, insomnia, anæsthesia, neuralgia, rheumatic gont, spermatorrhœa in the male and menstrual irregularities in the female. *Anæmia* also is the source of many of these diseases, though perhaps it is more frequently the effect.

*Anæmia* and *neurasthenia* may cause each other; *anæmia* is often the result of *neurasthenia*, and *vice versa*.

Both *anæmia* and *neurasthenia* are most frequently met with in civilized, intellectual communities. They are a part of the compensation for our progress and refinement.

*Anæmia* and *neurasthenia* may run into  
[WHOLE No. 2148.]

\* Read before the New York Medical Journal Association.

each other, and become so closely inter-blended that it is oftentimes impossible to determine which was the cause and which was the effect, or which is the ruling condition.

Both of these conditions, whether existing separately or in combination, are best treated by some form of constitutional tonics. In anæmia we give those tonics that directly and specially affect the *blood*; in neurasthenia we give those remedies that directly and specially affect the *nervous system*.

In regard to the pathology of neurasthenia we are compelled, in the absence of definite knowledge, to reason from logical probability.

My own view is that the central nervous system becomes dephosphorized, or, perhaps, loses somewhat of its solid constituents; probably also undergoes slight, undetectable, morbid changes in its chemical structure, and, as a consequence, becomes more or less impoverished in the quantity and quality of its nervous force.

That molecular disturbance, sufficient to give rise to the symptoms of nervous exhaustion, may take place in the central nervous system, is rendered logically probable.

The fact that such changes can be produced artificially, as proved by the researches of du Bois-Reymond.\*

We are, I think, driven to accept this view from what we already know of the brain and spinal cord—of their relation to the intelligence and activity, of their intimate chemical structure, of their diverse appearances in health and disease. We know that the intelligence of men and animals is proportioned to the quantity and quality of the cerebral contents, that the proportions of water, of phosphorus, of fat, and of the other solid constituents of the central nervous system vary more or less, with the age, and with the intellectual and moral capacity,† and that all forms of insanity‡ are dependent on *some* central morbid condition.

From these established facts we logically conclude that even the slightest and most transient disturbances of the nervous system are the results of correspondingly slight morbid changes of the brain or spinal cord, or of the peripheral nerves.

I admit that this view is speculative, but I feel assured that it will in time be substantially confirmed by microscopical and

\* See Reynolds's System of Medicine, vol. ii., p. 48.

‡ Maudsley's Physiology and Pathology of the Mind, p. 59.

chemical examinations of those patients who die in a neurasthenic condition.

Neurasthenia may result from any causes that exhaust the nervous system. Hereditary descent terribly predisposes to neurasthenia, just as it predisposes to all forms of nervous derangement. The law of *reversion* is frequently illustrated here, and sick headache, epilepsy or insanity or dyspepsia in the grandfather may skip over a generation and show itself as neurasthenia in the grandchildren. Among the special exciting causes of neurasthenia may be mentioned the pressure of bereavement, business and family cares, parturition and abortion, sexual excesses, the abuse of stimulants and narcotics, and civilized starvation, such as is sometimes observed even among the wealthy order of society, and sudden retirement from business.

The *diagnosis* of the neurasthenic condition is sometimes entirely clear, and again is quite difficult. The diagnosis is obtained partly by the positive symptoms, and partly by exclusion. If a patient complains of general malaise, debility of all the functions, poor appetite, abiding weakness in the back and spine, fugitive neuralgic pains, hysteria, insomnia, hypochondriasis, disinclination for consecutive mental labor, severe and weakening attacks of sick headache, and other analogous symptoms, and at the same time gives *no evidence of anæmia or of any organic disease*, we have reason to suspect that the central nervous system is mainly at fault, and that we are dealing with a typical case of neurasthenia. But neurasthenia may be associated with anæmia and with almost every conceivable form of organic disease. In such cases it is sometimes very difficult to ascertain whether it is the cause or the effect. The history of the symptoms will help us to decide this question; which is, however, of little import, for in either case the general treatment will be substantially the same.

The *prognosis* in neurasthenia is as various as are the symptoms of the disease. Acute neurasthenia resulting from acute disease usually recovers rapidly; but sometimes becomes chronic, especially when the previous disease has been long and exhausting.

Chronic neurasthenia—of which form I am chiefly speaking—may result in paraplegia, in general paralysis, in neuralgia, in uterine disturbances, in dyspepsia, in chorea, in hypochondriasis, in hysteria, and in actual insanity; or under proper treatment it may go on to perfect recovery.

Chronic neurasthenia sometimes proves

directly fatal, without causing any organic disease; but such a termination is not usual. It is, *par excellence*, a chronic condition, and patients afflicted with it may last for half a century. We are all of us more or less familiar with such cases. I have a friend who has been afflicted with neurasthenia for more than fifty years, and yet during all this time he has been severely engaged in the complicated duties of a lawyer, a judge, and a man of business. There is not an organ of his body that has not suffered from this prolonged neurasthenia; from the time he was fifteen years old until now there has been no day in which he has been free from pain. Even anæmia has supervened, but though the lamp of life has often flickered, yet at the advanced age of seventy it still "holds out to burn."

It is an established fact that opium eaters who are poisoned and weakened by the drug, are comparatively exempt from many other diseases. Opium eaters, I believe, all agree that it is very hard for them to take cold while under the influence of the evil habit. Just so, neurasthenia seems to protect the system from many acute diseases that so often prove fatal to the hardy and muscular.

Ralph W. Emerson, in one of his essays, quotes an authority who very happily compares a republic to a raft, which never sinks, but always keeps our feet under water, while a monarchy is a stately ship that may at any time strike a rock and go down in an instant.

This comparison just as aptly illustrates the difference between the nervous civilized man and the hardy barbarian. From statistics that I compiled and arranged a few years since, it appears that the expectation of human life or average longevity has at no time been greater than in the present century; that in no other country is it so favorable as in our own, and that no class, on the whole, live longer than our leading brain-workers, who are, of course, peculiarly liable to be affected with chronic neurasthenia.

But though neurasthenic patients live, they "live at a poor, dying rate," and demand and need relief, and many of them are very fortunately quite amenable to treatment.

The one principle on which neurasthenia is to be treated is by the concentration of all possible tonic influence on the nervous system—air, sunlight, water, food, rest, diversion, muscular exercise, and the internal administration of those remedies, such as

strychnine, phosphorus, arsenic, &c., which directly affect the central nervous system.

The nervous tonic which I largely employ in neurasthenia is *general electrization*. In this method of treatment the feet of the patient are placed on a sheet of copper to which the negation pole is attached, while the positive, either a large sponge or the hand of the operator, is applied over the head (the hair being previously moistened), on the back of the neck, down the entire length of the spine, down the arms, over the stomach, liver, bowels, down the lower extremities—in short, over the entire surface of the body, from the head to the feet; but with special reference to the head and spine.

The evidences that the electric currents when thus applied over the head and spine directly affect the brain and spinal cord, and, to some extent, the nerves that issue from them, are the following:

1. The investigations of Dr. Erb, of Germany.\*

By experiments on the cadaver he proved that the galvanic and Faradaic currents directly affected the brain and spinal cord—the galvanic more than the Faradaic.

2. My own repeated observations in cases of myelitis. In some cases of inflammation and even of congestion of the cord, an exceedingly weak current (either galvanic or Faradaic) will sometimes cause the most acutely painful sensations, both in the cord itself, and in the peripheral nerves that go to the viscera and the extremities. On the other hand there are cases of nervous disorder, where the nerve-centre is in a condition of partial anæsthesia, and consequently bears much stronger applications of electricity than when in a normal condition.

3. The remarkable tonic effects that are produced by applications of electricity over the head, and down the spine, even when the rest of the body is not touched.

These tonic effects of general electrization may be explained in two ways.

*First*, the electric current may directly improve the quantity and quality of the vital force, in accordance with the theory of the correlation and conservation of forces.

*Secondly*, the violent and repeated muscular contractions that are produced during the operations of general electrization greatly increase the processes of waste and repair. I once supposed that this passive exercise of the various tissues of the body, internal as well as external, might be the only ex-

\* Deutsches Archiv. 3 Band. IX.

planation of the results obtained by general electrization.

That this view was a mistaken one is proved by the fact that these tonic effects are very markedly observed from applications of a mild galvanic current over the surface of the body, even when no muscular contractions are produced.

The power of general electrization to relieve neurasthenia and to cause increase of weight, was illustrated in a very pleasing and satisfactory manner in the case of a young physician whom we have treated during the present autumn. He was 28 years of age, and for a long time he had been subject to severe and repeated attacks of nervous and sick headache. To use his own expression, he had been "living on a lower plane than was normal." Over work and long confinement had reduced him to a condition of serious exhaustion, and when he called upon us in September he could not walk two miles without fatigue. Although 5 feet 9½ inches in height, he weighed but 112 pounds, and for many months there had been no sign of any increase. He had closely studied his own case, had been thoroughly examined, and had tried nearly every form of internal medication.

I began treatment by a mild application of electrization with the Faradaic current. He felt temporarily enlivened and exhilarated, but when he returned two days subsequently, he stated that he felt no special benefit, although he had gained *one half a pound in weight*. This change, slight as it was, encouraged him, for it had been months and years even, since he had been able to detect any increase in weight. I may say here that he watched and studied his symptoms, and carefully ascertained his weight, from day to day, not as a hypochondriac at all, but as a scientific man, inspired not by any special faith in the remedy, but by an earnest desire to test for himself the tonic effects of general electrization. He continued to increase in weight with remarkable regularity and uniformity, and at the end of three weeks he found that he had increased nine pounds. When I last saw him his weight was 124 pounds. The improvement in his general condition has gone on hand in hand with the increase in weight. His appetite is keener, and his digestion much easier. His attacks of headache still annoy him, but his capacity for endurance has been greatly enlarged. Whatever relapses may occur in coming months or years, he feels now that he has at least found a means of relief and permanent benefit.

In this case the applications were made very thoroughly, all over the person from the top of the head to the feet, and with a powerful current. Both the Faradaic and galvanic currents were used, chiefly the Faradaic. It is worthy of remark, also, that this patient always experienced a feeling of temporary enlivenment and exhilaration after each application, and sometimes the headache from which he suffered was driven away in the midst of the treatment.

I may say, also, that when he first came I prescribed oxide of zinc, by *exclusion*, because he had used nearly every other internal tonic. He took, however, two or three doses of one grain each, for the first day, dropping it entirely as soon as he found that he had increased half a pound in weight.

This case I regarded as preëminently a typical one—a typical illustration of neurasthenia and of the benefit that may be received from general electrization.

But sometimes the treatment is protracted for weeks before any decided and permanent benefit is received.

This was well illustrated in the case of a stout, plethoric gentleman, whom we treated for neurasthenia in the summer of 1868. He was treated for several weeks before we could detect or could appreciate any very decided benefit. Finally we alternated the galvanic with the Faradaic current, and succeeded in affording him positive relief from many of the symptoms of nervous exhaustion from which he had suffered for years.

There are cases of neurasthenia that do not yield to general electrization, even after it has been perseveringly employed. These exceptional results may be variously accounted for. It may be that our diagnosis is wrong, and that organic disease of some kind is stealthily eating out the patient's life. It may be that their nervous systems are exhausted beyond restoration. It may that severer applications and larger perseverance might have resulted in positive benefit.

Dr. Rockwell and myself have records of 30 cases in which nervous exhaustion seemed to be the leading condition. Some of these cases were complicated with hemiplegia, paraplegia, hysteria, hypochondriasis, and so forth; but the majority complained chiefly of, and only sought treatment for, the *general* symptoms of nervous exhaustion, as I have described them. The results of treatment are as follows:—

Cured . . . . .	4
Greatly benefited . . . . .	16
Slightly benefited . . . . .	5
Not perceptibly benefited . . . . .	5
Total . . . . .	30

A few of those who were slightly or greatly benefited have measurably relapsed; but up to the present time the majority, so far as we can learn, have retained or increased the improvement they received. Two or three of the cases that relapsed are now under treatment.

In the limited time allowed me on this occasion it has been manifestly impossible to do anything more than to present the outlines of so important a subject as neurasthenia. I have, therefore, not aimed to be exhaustive, but only to be *suggestive*.

The principles on which I mainly insist and to which I call special attention, are briefly these:—

1. The term neurasthenia, as expressive of a very important and increasingly frequent condition of the system, is eminently justified by philological analogy, by convenience and by necessity.

2. The one principle on which this morbid condition should be treated is by the employment, either separately or together, of constitutional tonics, that specially affect the nervous system.

3. Among the various internal and external tonic remedies for neurasthenia, general electrization is oftentimes preëminent. The superiority of general electrization in cases where internal medication has failed, is apparent in the ease and rapidity with which it increases the appetite, promotes sleep, and develops the size and weight of the muscles—thus preparing the way for the *digestion of food*, which is itself one of the very best of tonics; for *rest*, which is really food for the nerves; for muscular exercise, which, in its turn, prepares the way for air and sunlight.

In this capacity of general electrization for marshalling to its aid other tonic influences, lies, I think, the secret of its power, perhaps the best interpretation of its success.

#### AN ADDITION TO CAMMAN'S DOUBLE OR BINAURAL STETHOSCOPE, INTENDED TO REGULATE THE AMOUNT OF PRESSURE ON THE EARS.

Messrs. Editors:—At the last meeting of the Suffolk District Society I presented an addition to the double stethoscope. Ac-

companying this communication is a cut representing this instrument with the addition.

As the double stethoscope is very little used, even in this country, where it was invented, except by graduates of Harvard and Bellevue, and almost never, I believe, abroad, convinced of its great superiority over the single instrument I will briefly mention the reasons for this superiority, and then speak of the addition which has been recently made to the instrument.

Its advantages are:—

1. It greatly intensifies sound. Most of the single instruments simply conduct, a few slightly intensify them.

2. It is much more easily applied to the chest, and maintained in place—a certain amount of knowledge of the art of balancing seeming almost necessary to manipulate the single instrument successfully.

3. We can keep our eyes upon the pectoral extremity, and thus be assured of its perfect adaptation, and prevent the friction of clothing, &c.

4. It excludes from the ear sounds not conducted by the instrument. The statement once made by Prof. Flint, that “in the conduction of thoracic sounds by Camman’s

binaural stethoscope, their quality and pitch were altered," has been since corrected by him, and he says that after further use of the instrument he finds "the objection on this score without foundation;" and he adds "I am sure that this instrument will supplant all wooden stethoscopes, as soon as it is fully appreciated. . . . Some practice is requisite to realize its value; hence many reject it after an insufficient trial, when, had they continued to use it, they would have been after a while unwilling to give it up."

The instrument consists of a bell-shaped extremity N, made of ebony, one inch and a half in diameter, to which are attached two elastic tubes M M, three inches long, and one half an inch in diameter, made of wire and covered with silk, which articulate at L L with two German silver tubes B B crossed, about ten inches in length and one quarter of an inch in diameter, which terminate in ivory or hard rubber tips A A, to fit into the ears.

The adaptation of these tips was formerly effected by a simple elastic band, passing about the tubes B B, these tubes being connected by arms meeting in a joint at K.

The only way in which the pressure on the ears could be varied, was by lengthening or shortening the elastic band, or by slipping it up and down on the tubes. The great inconvenience of this was particularly evident in my classes in auscultation, where the stethoscope was passed from one to another, and where not only were heads of all sizes, but where naturally much difference of opinion existed in regard to the amount of pressure desirable.

About a year ago I stated the difficulty to Mr. Moses G. Farmer, well known to our profession for his connection with the physiological experiments of Dr. Upham, in the case of M. Groux, and he immediately suggested the addition represented in the cut. C J represent a standard (so fixed as not to interfere with motion in the joint at K), the upper part of which is a screw. II represents a slide movable on this standard, F a spiral spring, and D a nut. G G represent two arms attached by simple box joints to the slide at I I, and to the German silver tubes at E E.

It will be readily seen how the pressure of the tips A A upon the ears can be nicely regulated, by regulating the tension of the spiral spring F by turning the nut D.

O represents a smaller pectoral extremity, which can be used sometimes with advantage in localizing heart murmurs, or when the application of the larger one is difficult

on account of emaciation of the patient or other cause, but ordinarily the larger one should always be used. The instrument, with and without the addition, is made in a superior manner by Messrs. Codman and Shurtleff, 13 and 15 Tremont street.

In closing I would strongly urge all who practise auscultation to use the double instrument, and would simply suggest that they be not dissuaded from its use by the *roaring* which will annoy them at first but which they will soon disregard; that they never apply it over clothing except when absolutely necessary, and that they make inference from the results with great caution.

F. I. KNIGHT.

### CEREBRAL AMAUROSIS.

By Dr. IG. MEYER, K.K. Kreisphysicus in Steyer.

[Translated for the Journal by B. JOY JEFFRIES, A.M., M.D., from the Vienna Weekly Medical Journal.]

(Continued from page 155.)

*Trouble of mobility in the limbs*, especially as hemiplegia and paraplegia, was a pretty often noted symptom in the recorded cases, more particularly in diseases of the spinal cord, of the pons and crus, apoplectic effusions, pus and softening in the brain, and with tumors of the hemispheres (4 times in 22 cases). Unilateral paralysis comes apparently most generally with unilateral affections of the pons, corpora striata, optic thalami, and the middle lobes of the cerebrum. According to Romberg, paralysis of one arm or one leg, when dependent on cerebral affection, has its seat always in the cerebrum. Thus in a case of Rosenthal's (*Med. Halle.*, 1863) there was an irregular mass over the left half of the partly flattened pons, and reached over the crus cerebelli ad pontem, left, to the left half of the small hemisphere; the trigeminal was compressed, and the neighborhood of the left facialis and acusticus softened to a mass. Corresponding to this there was during life severe and oppressive pain in the back of the head and temple, amaurosis of both eyes, right-sided paralysis of the facialis and anæsthesia of right side of the face to the lower angle, loss of smell and taste on right side, paralysis of the right abducens and paralysis of the left upper and lower extremity. In a second case in which there was also a tumor in the left half of the pons Varolii and left crus cerebelli, paralysis of the right extremities existed, paralysis and anæsthesia of the left half of the face, then paralysis and anæsthesia of the trigeminal, abducens, facialis

and acusticus, smell and taste weaker left, and imperfect articulation. In a third case, finally (an irregular mass the size of a walnut on the left process cerebelli ad pontem) the left half of the face was paralyzed, the speech unintelligible (intermittent sleeplessness), confusion of objects, difficult motion of left upper and lower extremity.

*Sexual anomalies* were occasionally referable to the diseased condition of the cerebellum. Of the recorded cases, there was only once increased sexual desire, in a man aged 52, where the anterior part of the cerebellum was softened to a pulp, in the centre of which was an apoplectic effusion.

Very praiseworthy attempts have recently been made to diagnosticate the form of the cerebral disease, and more particularly its locality. The difficulties in reference to the diagnosis which still exist in all such cases, authorize us to glean what we can from the records touching this point.

Exudations at the base of the brain and in the ventricles are more readily diagnosticated from the course of the disease and the symptoms. Most prominent and constant were headache (7 times), vomiting (7 times), sopor and coma (5 times), convulsions (4 times), and, finally, difficulties in the motion of the eye. Wunderlich gives as the principal symptom mental bewilderment, progressing to imbecility or idiocy.

*With softening of the brain*, the most frequent symptoms were headache, troubled consciousness, convulsions and paralysis. Difficulties of speech were only in two cases expressly noticed as morbid symptoms. Changes in the mental condition also but twice. (According to Wunderlich these last, and difficulty of speech, especially when it is rapidly followed by hemiplegia, indicate the existence of softening.)

*With cerebral abscesses and pus formation*, there came pretty constantly, headache, often sopor and coma, convulsions and hemiplegia. More seldom noticed were dizziness, mental alterations, epilepsy and troubled motion of the eye. Besides these, headache very intense, dizziness, clonic cramps and twitching, paralysis of one half of the body or one extremity, contractions of the face and deviation of the tongue were recorded as general symptoms of cerebral abscess; more rarely, any marked disturbance of the senses, of sight namely.

In cases recorded as *apoplexy*, besides the usual difficulty of motion (hemiplegia) the principal symptoms were headache, troubled consciousness, dizziness and mental changes. In cerebral hæmorrhage, weakened intelligence and lack of power of

speech accompany the complete hemiplegia; generally facial paralysis, deviation of the uvula and soft palate, and impeded motion of the tongue. The symptoms vary greatly here with the locality of the effusion. In apoplexy, where there is only unilateral disturbed motion, and the mental faculties remain perfect, it may be assumed that the extravasation has taken place in the corpora striata or optic thalami (the centres of motion). Where aneurisms were found, the most frequent appearances were headache, dizziness, impeded movement of the eye, and the consciousness affected.

In *cerebral tumors*, the diagnosis is more difficult, and their locality is hardly if at all to be determined. Cerebral tumors, as is known, often remain a long time latent, especially during their early development; this applies to tumors in the deeper layers of the cerebellum, the posterior lobes of the cerebrum, in the ventricles, often the lateral ventricles, as also with tumors of moderate size in the cortical substance and the surface of the hemispheres. The symptoms much depend upon the pressure which such tumors exercise on definite portions of the brain, as well as on certain nerves, upon the extent of the tumor, and also the accessory hyperæmia, inflammation, extravasations in them or their neighborhood.

Most generally, cerebral tumors first manifest themselves by symptoms of irritation (headache, dizziness, tonic and clonic cramps, disagreeable sensations, pain at various points), and after this by paralysis (commonly hemiplegia), which never comes suddenly, but gradually. The mental functions are impaired, memory and power of thought weakened, and finally complete inability; often there are attacks of epilepsy, and, as final symptoms, marasmus, coma and death. The diagnosis of a tumor is only possible when several functions of the brain are impaired and paralyzed at the same time, the paralysis of a part gradually developing by increasing weakness, and symptoms of irritation existing, temporary or constant, beyond the district of the paralysis. Impairment of the various senses, especially of vision, as also sleepiness, temporary unconsciousness, stiffness in the neck, a sensation of numbness and uncertainty, convulsive twitchings, vomiting without definite cause, are always grave symptoms.

If we endeavor to draw some conclusion as to the locality of the tumor from the appearances especially noticed in these cases recorded, and compare them with what was

observed in the later periods, we may deduce the following:—

1. Tumors in the hemispheres (most frequent in the noted cases) besides the troubles of vision, had, as general symptoms, headache (in nearly all cases), disturbed consciousness, dizziness, and as less frequent appearances formication and deafness, epileptic attacks, hemiplegia, convulsions, sopor and coma and troubled mobility of the eye. In irritating tumors of the peripheric parts of the cerebrum there are often contractions and convulsions, the signs of paralysis and irritation interchanging.

According to the very instructive analysis of Prof. Duchek (*Jahrb. d. Gesellsch. d. Aertze in Wien* 4 Heft. Sept. 1864, &c.) in disease of the anterior lobes (not only tumors but abscesses) there were troubled consciousness and disturbed mental functions; impaired speech only twice in six cases, as also headache, epileptic attacks and paralysis (of the opposite extremities) twice, in the majority sopor and coma towards the end. According to Wunderlich, tumors of the anterior lobes have no constant symptoms. He speaks, however, of impaired mental functions, impeded articulation to complete loss of articulation, and epileptic attacks, as symptoms in some cases. Affections of the convex surface of the cerebrum have, according to Duchek, no definite symptoms. Wunderlich gives disturbance of the mental functions, weakness and partial paralysis of the extremities and facial muscles of the opposite side, in broad tumors of the convex surface, which extend deep inwards.

According to Duchek, there are no disturbances of the mental functions and the senses, in diseases of the middle lobes. Headache was present with all, and subsequent symptoms of paralysis; in one case there were attacks of dizziness, in another of epilepsy. Tumors of these parts can of course affect the trigeminal, trochlearis, abducens, oculomotorius and sometimes the facialis of the same side, interfering also with vision. Duchek says in disease of the posterior lobes (two cases) there were in one case epileptic attacks and paralysis of the extremities of the opposite half of the body.

Vision was destroyed in two cases (Friedrich, Davison and Wunderlich).

With tumors of the corpora striata and optic thalami in which imbecility was present, there were headache, sopor and coma, with difficulty of motion as constant symptoms. Besides these were seen convulsions, photophobia, morbid sensitiveness to sound and vomiting.

According to Duchek unilateral paralysis on the opposite side of the body occurs, with affections of the corpora striata and optic thalamus. In a case of sarcoma of the left optic thalamus (Leyden) there was paralysis agitaus.

In two cases of tumors of the corpora quadrigemina, besides trouble of vision, there was constant headache and dizziness. In isolated disease of the corp. quadrigemina (tubercle in cases of Hensch and Steffen) double paralysis of the oculomotorius (ptosis, squint) was the principal symptom; we may have besides these, symptoms of paralysis in the facialis and the extremities of that side, and, finally, general convulsive cramps.

In tumors at the base of the brain and *fossa sylvii*, besides troubled vision, headache alone was pretty constantly observed. Convulsions were seen three times, disturbance of mental functions twice, and epileptic attacks twice noticed among nine cases.

Tumors of the pituitary gland are of especial interest, as they so often affect the sight. In twenty-two cases headache always occurred. As other symptoms were noticed, paralysis three times, vomiting, sopor and coma with mental disturbance five times, dizziness three times, excitation of the higher senses three times, convulsions, difficulty of swallowing, disturbed consciousness twice.

Duchek, in his two cases, speaks of periodic headache, dizziness, scintillation before the eyes, impaired vision and squinting. Wunderlich speaks of trouble with the sense of smell. In the majority of the cases, however, these symptoms are not much attended to.

[Hedland records (*Ammon's Zeitschr. f. Ophth.* B. V. p. 367) the case of an amaurotic woman who had a tumor of the pituitary gland and disorganization of the brain, with such severe pain in the perfectly healthy pharynx, that she thought she had a tumor there. Paralysis seldom occurs, according to Romberg, with affections of the pituitary gland and its neighborhood; the same in the cases reported by Engel.]

Tumors of the pons and crura cerebri occasioning amaurosis (10 cases), had, as other constant symptoms, headache (8 times), hemiplegia (6 times), and impeded articulation (5 times); besides, occasionally, formication, troubled mobility of the eye (6 times), sopor and coma (each 4 times), difficulty of swallowing (3 times), vomiting twice, twice hearing affected, and twice other senses affected.

The symptoms in affections of the pons

and *crura cerebri* were most thoroughly studied. Duchek noticed paralysis of the oculo-motorius of the same, and of the extremities of the opposite side, in diseases of one crus cerebri. Weber gives as accompanying them, paralysis or weakening of the vagus and sympathetic and impeded function of the intestine.

Duchek gives a résumé of 15 cases of disease of the pons. In cases where death took place in a short time from hæmorrhagic effusion in a large part of the pons, there was sudden unconsciousness and loss of speech, paralysis of motion and sensation in the limbs and great contraction of the pupils. (Brown-Séquard refers this symptom, which in unilateral affections occurs on the opposite side, to trouble of the fifth within the pons.) In cases where there was a more gradual formation of the alterations (tumors), or when with only partial destruction of the elements of the pons life lasted some time, paralysis of the facial nerve appeared either on the same or the opposite side, paralysis of the extremities of the opposite side, or paralysis of all four extremities and the tongue. Intelligence was also affected. In a case of Stein's with chronic primary tubercle of the pons Varolii, intelligence was perfect, but there were affections of the trigeminal and facial and collateral paralysis.

The cases also published by Rosenthal show that tumors of the pons, besides causing paralysis of the motor nerves of the globe, produce also paralysis of the facialis (sometimes of the trigeminal) and hemiplegia of the opposite side. He says that there is generally amblyopia or amaurosis of both eyes, and that smell and taste are sometimes affected; tumors of the middle portion of the pons extending into and pressing the medulla oblongata cause paraplegia or general weakness of all the extremities, mental impairment, difficulty of memory and thought and speech, which last symptoms he refers partly to paralysis of the facial, partly of the hypoglossus, by the tumor pressing on the olivary or pyramid of the medulla oblongata, or on the under wall of the 4th cerebral ventricle.

Affections of the *cerebellum* were rare among the above collected cases of amaurosis. In one case besides it, there was unsteady gait, and pain in the ear, pain in the back of the head and vomiting. According to Wunderlich tumors of the cerebellum generally affect the sight, squinting was not constant but frequent (pressure on trochlearis); the facialis and acusticus were also generally affected.

The most constant symptoms of disease of the cerebellum are, according to Duchek, troubled mobility (general muscular weakness, uncertainty of gait, staggering), the patient walking in a curve to one side or the other. Lack of co-ordinate movement is also noticed with affections of the cerebellum. According to Scherer the pupils are always dilated, the reverse of their contraction in diseases of the pons, only in rapidly fatal hæmorrhage and the invasion of the neighboring parts are they contracted. Jackson, notwithstanding the frequency of amaurosis, does not consider the cerebellum as the centre of the optic fibres, since Comette found, in congenital absence of it, all the senses normal. The amaurosis is due perhaps to participation of the optic thalami. There were no symptoms on the part of the genital system.

In extended *multiple tumors* the symptoms are of course very varied, and any deduction or reference much less possible. In the above seven cases headache (5 times), impaired motion of the globe (4 times), paralysis, convulsions and vomiting (each 3 times), were the principal symptoms. Hearing was affected twice, smell once.

In amaurosis where disease of the spinal cord was found, there were generally present all those symptoms accompanying such affections, namely, paralysis, formication, and impeded articulation. Dizziness was only twice expressly noticed. Hearing or the other senses seldom affected.

In locomotor ataxy (Duchenne), where the posterior roots and posterior cords were affected, impaired sight was noticed, early impeded gait from lack of co-ordination, impaired sensation of touch, and at the same time hyperæsthesia.

Paralysis of the ocular muscles generally preceded the gradually progressive amblyopia. Unilateral dilatation of the pupil was sometimes noticed (if the hardening reached high up in the cervical part of the cord in the upper cervical ganglia, where the commencing irritation or hardening caused a spasmodic condition of the dilator).

Amaurosis may occur also in caries of the spine, a case of which Rosenthal reports (Wiener med. Presse. vi. Jahrgang. nr. 45). A woman, æt. 54, had an S-shaped curvature of the spinal column, a point painful to pressure or without it, over the left posterior crista ossis ilei, hyperæsthesia and severe neuralgia of the thigh and leg, gradual loss of power of walking, and amaurosis of both eyes (ophthalmoscopically, discoloration of the optic papillæ, fatty degeneration of the optic fibres). The other symptoms

in this case were, a bitter taste, occasional gnawing in the stomach, at certain times during the night or day extended redness and burning in one ear and side of the face, periodical increase of temperature and sweating of the left foot and leg; all which denoted irritation of the cerebral and vasomotor nerves; these latter for the limbs, according to the late experiments of Schiff and Bezold, come from the medulla oblongata and spinal cord and partly also from the sympathetic, and so reach the nerves of the extremities.

## Bibliographical Notices.

*A Practical Treatise on the Diseases of Women.* By T. GAILLARD THOMAS, M.D., &c. &c. Second Edition, Revised and Improved. Philadelphia: Henry C. Lea. 1869. 8vo.

This book consists of 647 pages of lucid, condensed, and instructive reading matter, clearly printed in good sized type. There are also no less than 225 illustrations unusually well executed. We have seldom read a medical book in which we found so much to praise, and so little—we can hardly say to object to—to mention with qualified commendation. We had purposed a somewhat extended review with copious extracts, but we hardly know where we should have space for it. We therefore content ourselves with expressing the belief that every practitioner of medicine would do well to possess himself of the work, and to make himself master of its contents. One extract only we give, as furnishing the key-note of the author's uterine pathology. Dr. Thomas had been present in Paris in 1854, during the discussion at the Academy of Medicine with reference to the treatment of uterine displacements, and paid strict attention to its progress. Influenced, he says, "by the arguments which it elicited, and by the teachings of Valleix, whom I daily followed at La Pitié, I was convinced of the truth of Velpeau's position [that displacements are the main thing in uterine pathology]. Experience, however, has led me to dissent from it. I have found most of my cases of displacement which were attended by evil symptoms, to be accompanied by marked evidences of inflammation; have found them usually susceptible of no permanent benefit from replacement; and have obtained relief from the symptoms for which I was called chiefly by means which cured uterine in-

flammation. I have noticed that similar displacements almost invariably result from inflammation which commenced when the uterus was in its proper place; and have seen complete retroversion of the womb where no inflammation existed, produce, after the patient had become accustomed to it, no symptom. These observations have led me to discard the belief in the mere dislocation as being commonly the cause, and induced me to regard it as generally a result of inflammation. In making this statement I am not, however, disposed to deny the occasional morbid agency of uncomplicated displacement which may have resulted from inflammatory action, which has entirely passed away, or from force suddenly or gradually applied, or from loss of power in some of the uterine supports. A source of error which may arise in such cases as to the primary link in the chain of disease, exists in the fact that a displacement induced by the second or third of these causes will sometimes create congestion, inflammation and ulceration of the uterus."—Ed.

## Medical and Surgical Journal.

BOSTON: THURSDAY, APRIL 29, 1869.

NOTE FROM DR. J. B. S. JACKSON IN REPLY TO DR. OLIVER.

MR. EDITOR:—The criticisms in the last number of the JOURNAL by Dr. Oliver of my own (25th ult.) upon Prof. Oppolzer's lecture on "*Ulcus Rotundum Ventriculi*," require some remarks, and they shall be as brief as possible.

Dr. O. has collected a great amount of most valuable information upon the subject in question, and we must certainly be very much obliged to him for the good service that he has done; several of his statements being, I presume, more or less new to most of your readers, as they are to myself.

In my remarks before the Medical Society I made no allusion to authorities, but gave only the general impressions that I had received from the cases that I had seen; and it would be proper for me to state upon what number of cases these impressions were founded. It must have been one of those mere coincidences that we often meet with that Dr. Wood, of Philadelphia, did not see a case of the disease in question during a period of twenty-five years of Hospital practice; and it may be regarded as

a similar coincidence that a very considerable number has been met with here. The number, however, is small, as compared with what might be seen in Europe; but they seem to be enough to justify "general impressions." I was not at all pleased with Prof. O.'s lecture when I first read it; and almost at the moment of setting out for one of the late meetings of the Medical Society, it occurred to me to take the JOURNAL with me and make the remarks that were afterwards published. I had consulted no authorities, nor any of our recorded cases; but, since Dr. O.'s publication, I have examined these last, and they are as follows: In the Medical College Museum there are 14 specimens; in the Medical Society's Cabinet there are 5; and of my own dissections there are 8. Some of the two first were from patients whom I examined; many were received by me in a fresh state; and all of them were examined by me and recorded, more or less fully, in the Catalogues of the College and Society's Museum. One was not properly a case of ulcer, but a case in which there were the two distinct cicatrices of two ulcers; and one was the case of an elephant that I dissected in 1835, and in which a large, circular ulcer was found upon the pylorus. To the above cases, also, there might be added one of which I made a mere memorandum, and in which an ulcer upon the pylorus caused fatal hæmorrhage; and also Dr. Hosmer's case (JOURNAL, 8th inst.), as the specimen was shown at the last meeting of the Medical Society.

Dr. O. thinks that what I say of the term *Ulcus Rotundum Ventriculi* is trivial, but I cannot agree with him. If the name of a thing is descriptive, it should be as nearly as possible correct; and such names in science are very often objectionable, because, with the changes that are constantly going on, it is found that the description will not apply. I made a mistake in saying that the ulcer "always" tends to the round form, and I very well know that such is not the case. In fact, the specimen from Dr. Hosmer's case, above alluded to, was lying upon the Society's table when Dr. O. was reading his remarks, and was a remarkable exception to the contrary. I am well aware, also, that the ulcer is sometimes recent, and have seen a few such; but, when the ulcer looked somewhat so, the symptoms would perhaps show a chronic affection. In a lad who died at the Hospital in 1842, of acute necrosis of the upper maxillary bone, there were two large, gangrenous, and apparently acute ulcers in the stomach. Dr.

O. refers to Cruveilhier; but I think there can be no question that this author regarded the disease as essentially chronic, and only acute by exception.

As to some of my other trivial criticisms, I certainly was serious in what I said of Prof. O.'s free use of the Latin language. We have done away with a great many of the formalities of former times, and with much of our Latin, with the rest; and this change to a greater simplicity is a relief.—I was not aware until recently that the term "ice-pills," in the German, is so generally used; and, as Dr. O. remarks, the translation certainly might have been here improved.\* But it is generally the fashion to translate from the German very literally; and the consequence is that the simplest thoughts are sometimes almost incomprehensible.—What Dr. O. has remarked upon what I said of the "magistry" of bismuth is very true. It is no more objectionable than the term lunar caustic; but we have enough of such terms already, and do not want to have any more imported. Language in some measure is a matter of taste, and I did not attach any importance to these last criticisms, though I did to what was said of the term "*ulcus rotundum*."

In a sentence that I quoted from Prof. O.'s lecture a comma was inadvertently put in where there should have been none, as Dr. O. states. I can see no possible objection to it; but, on leaving it out, and even with the aid of the next sentence, the meaning is beyond my comprehension. The obscurity is in the expression "during the night."

I also allow that I misunderstood what Prof. O. says of the use of belladonna as a substitute for morphia.

In the case of perforation, it seems strange, as I remarked, that Prof. O. should not have alluded to the use of opiates; but it appears that in a lecture that was translated by Dr. Coolidge he does so. So important a point in practice, however, should, it seems to me, be alluded to by Prof. O. whenever he speaks at all fully upon the subject of perforation. In this last lecture referred to he says that opium is the best agent in "danger of perforation;" and if he means to say when there is a threatening of perforation, I would ask how he would be sure of this? In our cases, certainly, the accident occurs without warning.

Prof. O. says that the pain is "continu-

\* So far as we are informed the translation was quite correct. All that was wanted would seem to be a footnote explanatory of what the Germans mean by "ice-pills."—EDITOR.

ous" when perforation occurs—from peritonitis, of course; and Dr. O. remarks that he is not speaking of the severity of the pain. Now, that is just what I intended to say, and found fault with—that he does not speak of it. As to recovery in case of perforation, of which there would seem to be so considerable a chance, according to the authors quoted by Dr. O., I think that we must make some allowance for error of diagnosis; the existence of the disease in question being by no means always an established fact.

The proportion of 147 cicatrices to 156 ulcers, referred to by Dr. O., is something that would be inconceivable, were it not for the coincidences to which I have already referred as of such frequent occurrence. In the case of cicatrization that I examined, and above alluded to, the appearance upon the external surface was as if the organ had been stabbed through with a knife. One other very much less marked case I remember, but I cannot find the record. These, I believe, are all that I have seen; and I intended to make the number large enough when I said that I had never met with cicatrices more than two or three times. It is, of course, out of the question to hunt through a pile of cases for a negative.

As to the *conchæ preparate*, I am very sorry to see that I read Prof. O.'s remarks carelessly, and consequently misunderstood him; but I do not feel so sure as Dr. O. seems to that Prof. O. would not use the remedy if he thought it best, and let his patients bear with some disagreeable sensation in the stomach. And the allusion to the dog's dung might have been spared if Prof. O. had much objected to that remedy. When he has so much that is valuable to say to his class, his time might be better occupied than in referring to the objectionable and disgusting remedies of by-gone days.

As to some of the other points referred to by Dr. O.—the size of the stomach, the hour-glass contraction, the condition of the mucous membrane, the use of the term necrosis, the distention of the abdomen and the occurrence of phthisis at the close of the disease—I can only, after having examined the cases that have occurred here, reiterate what I have already said.

Before closing, I wish to say what I should have said in my first remarks, that I have always heard the very highest praises of Prof. O., as a man of erudition and especially as a clinical teacher. But I must add that, after making all due allowance for the criticisms upon my first re-

marks, there still seem to me to be some very objectionable points in the lecture.

Yours very truly,

J. B. S. JACKSON.

P. S.—It is of course understood that the cases observed here and above referred to were not common chronic ulcerations of the stomach, but cases of "chronic," "round," or "perforating ulcer," several of them terminating in perforation or hæmorrhage.

#### NOTES FROM THE GAZETTE HEBDOMADAIRE DE MEDECINE ET DE CHIRURGIE.

*Thoracentesis*.—A writer in the *Gazette* refers to its citation in 1863 of Dr. Bowditch's statistics setting forth that out of 75 patients subjected to thoracentesis 20 recovered their health, and pronounces the operation a therapeutic conquest of great value. Dr. Fossagrives takes the ground that the utility of the operation is "subordinated to a question of opportunity," i. e. that the time when it is done should be well chosen. He is in favor of early puncture—say when inflammatory action has begun to subside. While he cannot see what harm can come from premature puncture, he sees but too well, and in consequence of a long series of sad recollections, the injuries produced by an effusion which perpetuates itself, which compresses and crowds the lung, which puts upon it a cowl of unyielding false membrane, and which, in ordinary cases, leads the patient through a thousand dangers made up of asphyxia, of purulent formation, of hectic fever, to a condition which can only by comparison be called recovery, and which is attended with a functionally imperfect lung, and often with irremediable deformity of the chest.

*Della famosa Tarantola*.—The *Gazette*, quoting from the *Gazetta Medica Italiana Lombardia*, says we must renounce the marvellous history of the tarantula, and conclude that the stories about the effects produced by the sting of that colossal spider have sprung from imposture, credulity, and the effects of nervous disorders, of the nature of hysteria or of melancholy. Prof. Paolo Panceri has caused to be bitten by the *Lycosa tarantula*—to which has been most especially attributed *tarentism*—a turtle, on the lower lip; an aquatic salaman-

der, on the back; a pigeon, on the breast, &c. He then induced a tarantula obligingly to bite the upper lip of a rabbit. Finally, that nothing should be wanting to the demonstration, Prof. Francesco Gassi was happy enough to get himself bitten on the left hand. The result of the experiments—which were made in June and July, 1868—was that the bite of the tarantula does not differ from that of an ordinary spider, except that the former produces somewhat greater pain and swelling.

*The Nerves of the Cornea.*—The same journal quotes from the *Zeitschrift für Rationelle Medicin* von Henle u. Pfeufer, the experiments of Dr. H. Peter Möller on the nerves of the cornea. The conclusions of the German observer are to this effect. Having impregnated the nerves with chloride of gold, Dr. Peter Möller examined them as colored by that agent, and reports that though the "nerve tubes" cross the corpuscles of the cornea and are apparently in close contact with them, yet the former are never in real connection with the latter—are not "continuous with their substance."

CANCEROUS TUMOR SAID TO HAVE BEEN CURED BY GASTRIC JUICE.—M. Garnier, in the *Union Médicale* for April 10th, 1869, describes a case of tumor—alleged to be cancerous—of the left temporal region, removed, *digested away*, by gastric juice obtained from the stomach of a dog through an artificial fistula. The case was treated at the Hospital of Lodi, by Dr. Tansini, where the patient, a woman 52 years of age, entered the 13th of January, 1868. She was discharged the 19th of the following March, perfectly freed from her tumor, and in a very satisfactory general condition.

As no careful differential diagnosis had been set up, M. Garnier justly considers it doubtful whether the tumor were a cancer or a simple ulcerating epithelioma. He remarks that the acetic acid treatment imported into France from England was effectual in epithelioma, though not in cancer, and that if the tumor in Dr. Tan ni's case were the former, there was nothing strange in its destruction by gastric juice. M. Garnier, after stating that this agent had

been praised by Professor Lussana as capable of *digesting* tumors of "bad character," goes on to describe the rules laid down by that "physiological savant" for its employment; and adds that it only remains to test it upon ulcerated cancers, and fully declared scirrhus of the breast.

We would add the question whether there is any reason to suppose cancer of the stomach to be limited by the action of the gastric juice.

PHYSIOLOGY, &C., IN SCHOOLS. PROF. DALTON'S BOOK. EXTRACT FROM THE VALEDICTORY ADDRESS OF PROF. CLARKE.—"Formerly no instruction in anatomy, physiology, therapeutics or hygiene was given in our public and private schools. Now this is often done. The tendency of the age is in favor of the change. I will not stop to inquire whether this tendency is a wise one or not. I only state the fact, without discussing the principle that underlies it. The fact that the public demands, and that our schools are giving, instruction in medical and physiological matters confronts us, and we must accept it. Yet, I fear that the text-books employed, and the instruction given, are not of the best sort. A brief examination of some of the physiological and semi-medical books used in our schools has convinced me that they are far from correct. If it be true that a little knowledge is a dangerous thing, it is also true that misstatements, error and falsehood, especially when heralded by authority, are more dangerous still. They are then pernicious. It would be better for the youth of both sexes to grow up ignorant of the structure of their bodies and of the beneficent laws of health, and so be guided by the instincts which a good Providence has bestowed on man, than to be taught false theories and half truths. The latter are blind guides and lead to destruction. . . .

"Then let the experiment of rudimentary education in the various branches of medicine, especially in anatomy, physiology, therapeutics and hygiene, be fairly tried in our schools. Let it be tried in the best manner. If it fails, after a fair and satisfactory trial, it will be given up. But in order to make the experiment a fair one the medical profession must direct it. I cannot say that I have any hearty faith as to the good that will come of it. Yet I do not know—none of us can know—how far the knowledge of a peculiar and recondite science like medicine can be wisely diffused among the

public. We must wait the developments of the age, and accept the result. . . .

"One word as to text-books. Most of the books used for this sort of rudimentary and popular medical education have been written by imperfectly educated medical men, or by amateurs, or by charlatans. The result has been a sort of unwholesome medical literature, that has poisoned and not invigorated, that has misled and not enlightened the minds of our youth. If this difficulty can be remedied it will be for you to prepare and apply the remedy. If books of any real value can be produced they must be written by our most learned and accomplished physicians. The preparation of a good text-book for beginners implies the completest knowledge of a science on the part of its author. . . . You must master a science before you can explain its smallest fact."

Dr. Clark concludes his remarks on this head by rejoicing with the rest of the profession that "within the last year a text-book of physiology for schools and academies has been prepared by one of the most accomplished of American physiologists—Dr. John C. Dalton."

EXTRACTS FROM THE FIFTY-FIRST ANNUAL REPORT OF THE McLEAN ASYLUM FOR THE INSANE, JAN. 1, 1869.—Two hundred and seventy persons have been under treatment at the Asylum during the year just closed. One hundred and twenty-six of these were males and one hundred and forty-four were females. In the same time, ninety-two—thirty-eight males and fifty-four females—have been admitted. Ninety-four—forty-five males and forty-nine females—have been dismissed, leaving the number occupying the house to-day, one hundred and seventy-six, of whom eighty-one are males and ninety-five are females. The condition of those dismissed, has been registered as follows: thirty-four—sixteen males and eighteen females—*recovered*; seven—three males and four females—*much improved*; twenty-two—ten males and twelve females—*improved*; eight—four of each sex—*not improved*; twenty-three—twelve males and eleven females—*dead*. In the early part of the year, nineteen persons were discharged by your direction, whose condition did not appear to be such, either in appreciation of comforts, necessity of care, or prospect of cure, as would warrant, on the part of their friends or of the Asylum, the expenditure requisite for a longer residence here. This, however, has reduced the weekly average

number of persons to one hundred and sixty-six—a number less by twenty, than the average for many years. For many weeks, the whole number of patients was about one hundred and sixty. It has gradually increased, until it is to-day, one hundred and seventy-six—less by only two, than upon the first of January, 1868. This reduction of numbers has increased the average cost of board to each patient, while the ordinary expenses of the Asylum have not been very different from those of the year previous. . . .

Very nearly the same general and abundant means of occupation, recreation and amusement have been in operation, as have been described in former reports. We are again under great obligations to Dr. Walker and the Directors of the South Boston Hospital, for several charming harbor excursions for the patients; to Mr. Kimball for free admission to the Museum, and to Dr. Upham for tickets to the Great Organ Concerts. . . .

The Association of Superintendents of American Institutions for the Insane, held its last annual meeting in Boston. A part of one day was spent by the members in examining every portion of our premises, indoors and out, and a session for business was holden here. This Association, composed of medical men who are at the head of establishments for the insane in all the States, has for some years had under consideration "the legal relations of the insane." After many prolonged discussions and a careful examination of the subject in all its various aspects, a "project of a law" was unanimously agreed upon, as ensuring as far as legislation can, the prompt care of the patient, the protection of his personal liberty and the safety of the public. This "project" is printed as an Appendix to this Report.

EXTRAORDINARY RECOVERY.—The *Russian River Flag* of Feb. 11th tells the annexed:—

On our recent tour through Mendocino county, we made the acquaintance of B. F. Chase, a foreman in the Caspar mill, who received a wound in July, 1864, the nature of which, and his complete recovery, furnishes one of the most remarkable cases of the kind to be found on record. He was doing some work under a picket saw, which, when in motion, runs at a tremendous speed. Inadvertently raising his head against the saw, he instantaneously received a cut beginning at the frontal bone, one-half inch above the nose, and running back to the

occipital bone, making an incision nine inches in length (taking in the convexity of the skull). Dr. A. C. Folsom was sent for and arrived in half an hour. He very naturally supposed the wound was a fatal one, and at first thought that it would be useless to dress it, believing the man would die within a few minutes. But Mr. Chase being perfectly conscious and suffering no pain whatever, the doctor finally concluded to attempt a careful dressing, even if the patient should die under the operation—encouraged somewhat, he says, by remembering the case of the man in Vermont who had a tamping iron blown through his head and recovered therefrom. The cut in Mr. Chase's head gaped open so that the skull bones were a full inch apart. The doctor made no attempt to probe the depth, but did insert a pocket rule  $1\frac{1}{2}$  inches into the brain (besides the thickness of the skull-bone), which was as far as it would go without touching the walls of the cut. On account of its circular shape the saw must have penetrated the brain much deeper than a point on a straight line from one extremity of the wound to the other. Dr. Folsom estimated that the brain was cut nearly to its base, or fully three inches deep. He carefully removed all fragments of the skull—taking out over 30 pieces—and washed out the sawdust that had got into the opening, using warm water to promote hæmorrhage, which was slight for such an extensive wound. He also washed out more than a table-spoonful of brain. How much more the saw carried away we can only conjecture. The doctor then shaved the scalp, applied a tourniquet to bring the bones together, and closed the aperture with six stitches, finishing with adhesive plaster, and leaving three openings, one at each end and one in the centre. The only dressing ever used was cold water.

The patient was in possession of all his faculties during the whole time, and said he experienced no pain then nor afterwards until he was entirely recovered. He visited the mill in about four weeks after the accident, and soon after resumed his duties as filer and foreman, which position he still holds. He says he never lost sleep or appetite, or experienced any physical or mental pain or weakness from his wound. The doctor's theory for this wonderful case is that the wound was a clean, smooth cut, unaccompanied by concussion, and that it is usually the concussion and not the incision of the brain that causes death.

We are indebted for the foregoing facts to Dr. Folsom himself. He related the case

to us in presence of several gentlemen who were also acquainted with the circumstances. The Doctor said he would have sent a statement of the case to the medical journals shortly after the occurrence, but he was firm in the belief for a year or two that his patient would ultimately die of the injury.

Mr. Chase now seems to have as long a lease on his life as anybody, and as to his soundness of mind, we can say in proof that on reading the *Flag* he immediately subscribed for it.

The foregoing account was transmitted to us by a friend, to whom it was sent. We have no opinion to give on the subject of the alleged case. Since the antics of iron bars, gas pipes, and the like, skepticism is discomfited, and dares not utter itself. Brains do not seem to be of much account nowadays. At the same time consciousness does not reveal the existence in any part of our cerebrum of a belief that a man can have his calvaria sawed nearly off and live. Meanwhile, Dr. J. M. Harlow has undertaken to write to California, to ascertain what basis of fact there is for the story.

**WEIGHT OF THE BRAIN.**—At a meeting of the Vienna Society for Psychiatria and Forensic Psychology, prosector Dr. Meynert gave some statistics on the weight of the brain. His deductions from the weight of 351 brains, as well as those of Parchappe from 284, prove that the influence of psychoses is much greater than age on the weight of this organ. For example, during the physiologically blooming age of the brain's weight (30—40 years in males), a mean of only 1,317 grammes was given, because brains of the later stages of psychoses were mingled with the others weighed; on the other hand, in the primary stage of psychoses, without regard to age, a mean of 1,329 grammes was given for conditions of depression and 1,359 for mania. Furthermore, the reduction of weight was always equal to the duration of the disease. It was also found to depend upon the intensity of the latter, as paralytic idiocy was characterized by a great reduction of weight. Meynert also found that insane brains had more cerebellum, proportionally, than sane; and that insane females had more than insane males.—*Medical Press and Circular*.

At the recent commencement of the St. Louis Medical College the degree of M.D. was conferred on 47 graduates.

## Medical Miscellany.

OUR attention has been called to the following passage in the report (*Medical Times and Gazette*) of the Annual Congress of German Naturalists and Physicians:—

"Prof. Zenker, of Erlangen, who, as is well known, was the first to observe and recognize trichina disease in the living subject, communicated the results of his investigations into the 'Life and History of *Oxyuris vermicularis*.' He found that the real seat of this parasite—that is, the place where the female worms love to reside and congregate—is not the rectum, as has been generally assumed, but the cæcum; and that the males, which were formerly believed to be extremely rare, are just as numerous as the females. The history of the worm is the following:—Embryonic ova are swallowed; the embryos are set free in the stomach and grow up in the small intestines, being found in all parts of the latter from the duodenum downwards, and in all stages of development. They here undergo a process of moulting, and then assume the definite form of males and females. Fecundation frequently takes place in the small intestines. The females, after having been impregnated, rapidly migrate into the large intestines, while the males spend a longer time in the jejunum, and are found in large masses in the lower portion of the ilium, especially near the cæcal valve. A drop of mucus taken thence often contains a dozen males without a single female. Impregnated females accumulate in the cæcum, but the ova are not excreted in the cæcum, nor, indeed, in the upper portion of the large intestines. The development of the vitellus is now proceeding, but the ova are only set free in the rectum, near the anus, or after the worms have been discharged from the bowel. A further development of the embryos in the open air, or in an intermediate host, does not take place, and infection occurs by swallowing embryonic ova."

**KRISTELLER'S METHOD.**—Herr Hilderbrandt referred (*Berliner Klin. Wochenschrift*) to this method of expressing the fetus, at a meeting of the Königsberg Med. Society, April 14th, 1868. He first resorted to it with great hesitation, and in a case favorable for the trial it succeeded so well as to astonish him. It was in the case of a second pain, in transverse position, head on left ilium, four extremities presenting. An assistant had failed in an attempt to turn by the feet. He put back both feet, then the arms, caused the head to present by means of pressure from without, then made one or two strong compressures *à la* Kristeller, and saw, during the same, the rapid and happy birth of a living child. Since then he has tried the method in a number of cases, and recommends it.—*Dublin Medical Press and Circular*.

**EARLY TREATMENT OF THE INSANE.**—In the province of Westphalia the directors of the Marsberg and Lengerich Insane Asylums have ordered that native patients shall be subsisted free of cost during the first year of their malady. This is done in order that cases may be placed under treatment

while yet in the initial stage. They claim to cure 80—90 per cent. of all cases admitted during the first month of the disease, fewer with every additional month, and assert that incurability is the rule after one year's duration.—*Berliner Klinische Wochenschrift*.

**LOSS OF THE NAILS.**—Mr. Wilkin, of Staplehurst (*Journal of Cutaneous Medicine*), reports a case of obstruction of the brachial artery from embolism, produced by a fragment of fibrinous clot supposed to be detached from the left ventricle of the heart. The arm became pale, cold and shrunken; it was pulseless, and as it recovered its strength the nails of the fingers were shed.—*N. Y. Medical Record*.

## MEDICAL DIARY OF THE WEEK.

MONDAY, 9, A.M., Massachusetts General Hospital, Med. Clinic. 9, A.M., City Hospital, Ophthalmic Clinic.  
TUESDAY, 9, A.M., City Hospital, Medical Clinic, 10, A.M., Surgical Lecture. 9 to 11, A.M., Boston Dispensary. 9-11, A.M., Massachusetts Eye and Ear Infirmary.  
WEDNESDAY, 10, A.M., Massachusetts General Hospital, Surgical Visit. 11 A.M., OPERATIONS.  
THURSDAY, 9 A.M., Massachusetts General Hospital, Medical Clinic. 10, A.M., Surgical Lecture.  
FRIDAY, 9, A.M., City Hospital, Ophthalmic Clinic; 10, A.M., Surgical Visit; 11, A.M., OPERATIONS. 9 to 11, A.M., Boston Dispensary.  
SATURDAY, 10, A.M., Massachusetts General Hospital Surgical Visit; 11, A.M., OPERATIONS.

TO CORRESPONDENTS.—We depart from our usual course in giving a list of communications accepted. We do this because some of them being long several weeks will necessarily elapse before all of them get into print:—Phys. and Ther. Uses of Ergot; Indiscrim. use of Acid Medicines; Path. Anat. of Surg. Stumps; City Hospital Reports; Eye and Ear Infirmary Reports; Nomenclature of Cutaneous Dis.; Arrest of Development of the Eye; Constriction of the Oesophagus; Cancer of Kidney in Infant; Cases in Aural Practice; Notice of Lunatic Hospital at Harrisburg; Tedious Labor, Incision, &c.; Herpes Zoster Ophthalm.; Spontaneous Cure of Tumor during Pregnancy; Paralysis of Motor Nerves of the Eye; Typhoid Fever, &c.; Mania Transitoria.

BOOKS AND PAMPHLETS RECEIVED.—A Treatise on the Function of Digestion; its Disorders and their Treatment. By F. W. Pavy, M.D., F.R.S., &c. From the Second London Edition. Philadelphia: Henry C. Lea. 1869.—The Probe; An Inquiry into the Use of Stimulants and Narcotics, the Social Evils resulting therefrom, and Methods of Reform and Cure. By Joseph Parrish, M.D., Philadelphia.—Twentieth Annual Announcement of the Woman's Medical College of Pennsylvania.

DEATHS IN BOSTON for the week ending Saturday noon, April 24th, 96. Males, 42—Females, 54.—Absecess, 1—accident, 1—apoplexy, 1—asthma, 1—inflammation of the bowels, 2—disease of the brain, 2—bronchitis, 4—cancer, 3—consumption, 20—convulsions, 3—croup, 2—diarrhea, 2—diphtheria, 1—dropsy of the brain, 1—drowned, 2—dysentery, 2—erysipelas, 1—exhaustion, 1—scarlet fever, 11—typhoid fever, 1—disease of the heart, 2—infantile disease, 2—intemperance, 3—jaundice, 1—disease of the kidneys, 3—disease of the liver, 1—congestion of the lungs, 1—inflammation of the lungs, 4—marasmus, 1—measles, 1—cerebro-spinal meningitis, 1—old age, 2—paralysis, 1—peritonitis, 1—pleurisy, 1—premature birth, 1—scalded, 1—syphilis, 1—unknown, 6.  
Under 5 years of age, 35—between 5 and 20 years, 5—between 20 and 40 years, 25—between 40 and 60 years, 19—above 60 years, 12. Born in the United States, 67—Ireland, 21—other places, 8.

## Original Communications.

## THE PATHOLOGICAL ANATOMY OF SURGICAL STUMPS.

By Dr. CHAUVEL (Army Medical Staff).

Translated for the Journal from the Archives Générales de Médecine for March, 1869, by B. E. COTTING, M.D., of Roxbury.

WHILE two years attached to the Infirmary of the *Hôtel des Invalides*, we dissected and examined all the surgical stumps of those who died there during that period, and we propose to give a condensed statement of the results of our researches in the following paper, after a few words on the history of the subject.

*History.*—The first observations on the condition of surgical stumps date from the close of the last century. They were made in Germany, and form two inaugural theses. (Dezeimeris, Dict. de Méd.—Art. *Amputation*.)

In France Larrey took up these researches during his residence at the *Invalides*. The conclusions he arrived at may be found in volume third of his *Clinique Chirurgicale*. He insists mainly on the changes which take place in the divided nerves. He verifies the tumefaction of their extremities, from which (according to him) very delicate filaments issue to lose themselves in the cicatrices. He considers these filaments conductors of animal electricity. He meets with unusual reunions of divided nerves in three stumps of the arm; and sees in these nerve-anastomoses a provision of nature to prevent loss of nervous fluid by thus insuring its return to its source.

Changes in the osseous extremities did not escape notice. According to him, when these serve as supports upon their whole surface, they enlarge, and the ends become flattened, like nail-heads. On the contrary, when not pressed upon, or when hanging free, the ends diminish in all directions and become rounded; the medullary cavity closes up, and the fibrous periosteal tissue adheres to the cicatrix. Larrey sustains these views by seven autopsies.

Cruveilhier (*Anat. Path.*, iii. p. 755), un-

Vol. III.—No. 14

der the name of *traumatic neuromata*, designates the bulbs usually developed on the ends of the nerves in surgical stumps. He attributes their formation to the friction and pressure necessarily endured by these parts, as such formations never occur when nerves are divided in continuity. Dissection shows, says he, that nerve-filaments spread out into the surrounding mass, and are soon lost; but the supposition of anastomosing loops is, he thinks, without foundation in fact.

Guthrie (*Comm.*, p. 75) relates that he once knew an operation to be proposed where tenderness of the terminal bulb of the sciatic nerve, after amputation of the thigh, had been mistaken for disease. Fortunately he was able to dissuade the patient. We have many times endeavored to feel the terminal bulb of the sciatic nerve in patients whose thighs had been amputated, but have never been able to find it.\*

Hutin (*Anat. Path.*, &c.—*Mém. Acad. Méd.* 1855), long time Chief Physician of the *Invalides*, paid great attention to the condition of the several parts forming the stump. He studied the cicatrization of the arteries, finding them sometimes converted into fibrous cords, sometimes permeable to the very extremity, being simply obliterated by a long plug of fibrin, thick and discolored, without trace of organization.

He also examined with much care the nerve-bulbs, their appearance, structure, and termination. According to him, the filaments which issue from them are either nerve fibres, or simple cellular prolongations furnished by the neurilemma. The nascent bulb is formed by the retraction of the nerve substance within the neurilemma stretched by the cicatrix. At a later period it becomes more or less increased in size by addition of fat and hypertrophy of the neurilemma. He declares that re-union, end to end, of divided nerves does not exist in reality. By chance, nerves may be found involved in common fibrous tissue, and thus

\* . . . "The extremity of the principal nerve, which always enlarges, assumes a bulbous form, and is painful on pressure when made for the purpose, although not so under ordinary circumstances."—Guthrie, *Com.*, 1855, p. 75.—Tr.

apparently re-united, but there is never a true reunion of their substance.

The bones, he says, soften at their extremities; their walls contract; and the medullary cavity closes by a calcareous deposit in the cicatricial tissue. This substance in excess often forms prolongations, spines, and considerable masses, which, by pressure on the soft parts and nerves, cause severe pains to patients.

M. Notta has endeavored to show that the fibrous cord continues even to the cicatrix, and what is usually thought to be the obliterated artery is in reality only inodular tissue formed by the cicatrization of a fistula produced by the thread of the ligature.

Lobstein (*Anat. Path.*) calls attention to the mucous bursæ sometimes occurring on the osseous extremities in stumps; formed there, he thinks, by the repeated frictions these parts are liable to.

Legouest (*Chirurg. d'Armée*) admits the re-union of the nerve-extremities end to end. He describes growths on the ends of bones, from specimens in the collection of M. Ilutin, and gives figures of some of the most remarkable. He points out a different result in this respect, after disarticulations, where the bones, he finds, become atrophied.

Alphonse Guérin (*Nouv. Dict. de Méd. et de Chir. Prat.*, ii. p. 87) doubts the propriety of regarding the nerve-swollings in stumps as a disease like neuroma, whose symptoms they are far from presenting.

We may mention, also, as bearing upon our subject, a notice of the atrophy of arterial walls by Maurice Raynaud (*Nouv. Dict. de Méd. &c.*, iii. p. 232); and Nélaton's view of the transformation of an artery into a firm ligamentous cord (*id.* iii. p. 172). He regards this as constant after a section of a vessel, and as the normal mode of vascular obliteration.

*Researches.*—Our own conclusions are based upon thirty-two cases, as follows:—

Amputations, thigh	{ upper third,	3
	{ middle " "	4
	{ lower " "	4—11
" leg	" " " "	8
" arm	" " " "	6
" forearm	" " " "	1
" hand	" " " "	1
Disarticulation, ante-scaploid	" " " "	1
" shoulder	" " " "	4

32

In a general view, the form of the stump varied with the member amputated. In limbs of one bone (thigh, arm) the stump always tended to conicity. This was produced by muscular retraction, and some-

times had been increased by wearing an artificial limb. The skin was also retracted, and the cicatrix in this way so drawn upon as to keep up the tendency of the bone to protrude.

There was less conicity in members of two bones, as the shorter muscular fibres were fixed to the bones near by, and the skin, held down by more compact cellular tissue, had less freedom in retraction.

On first section of a stump one is struck by the abundance of fibrous tissue, dense and firm, enveloping the osseous extremity. It attaches muscles, nerves and vessels to the cutaneous cicatrix, and thus serves as a common bond, uniting all these dissimilar parts. Its volume is increased at the expense of other substance lost by the operation.

The actual state of the stump in our cases varied according to the disease to which the patient succumbed. If he died of a constitutional affection, cancer or tubercle, the stump shared the atrophy and emaciation characteristic of the last stages of such diseases. Its skin was then dingy and sallow, the muscles were atrophied, and all the parts infiltrated with serum. If, on the contrary, the patient continued in good case, the stump remained well nourished, while a deep layer of fat thickened the skin and enveloped the thoroughly degenerated muscles.

*State of the Cicatrices.*—Can the method of operation be made out by the form and position of the cicatrix? Not easily, says M. Legouest and rightly. In almost all the cases we examined the circular method had been practised; and, nevertheless, in our eleven amputations of the thigh, for example, we found six circular and five linear cicatrices, almost invariably drawn a little backwards and inwards. The cicatrix, in short, varied according as the union was wholly or in part by first intention, or interrupted in any way in its usual course.

In two disarticulations of the shoulder, however, the cicatrix clearly indicated the method employed, that of Larrey in the first, of Dupuytren in the second. In the amputations of the leg and arm, the method could not be ascertained by the cicatrix.

Cicatrices resulting from the same method not only varied in form and extent, but also in their nature and color; sometimes smooth, dull white, and quite thin, at other times violet, rugous, deeply injected and of great thickness. Generally the cicatrix adhered to the end of the bone by short interwoven fibrous bands. Occasionally these bands were elongated, and formed a mucous sub-

cicatricial bursa. We met with such a bursa three times.

*State of the Muscles.*—Fatty degeneration of the muscles has been described by all writers. It was recorded, with the atrophy that accompanies it, in almost all our observations. Naturally, a muscle mused loses its powers and normal structure. This is a gradual transformation, and requires considerable time. We met with it in all degrees, both in different subjects, and in different muscles of the same stump. In some the change was so slight that the color, volume, and tenacity of the muscle were as of healthy tissue; and the loss of strie, if any, in its fibres, and commencing granular condition, were ascertainable only by the microscope. In others the degeneration was so complete that the naked eye could perceive only a shiny, bleached, and almost fluid mass, breaking down under the fingers; while the microscope revealed large globules of fat, and only here and there vestiges of primitive tissue. In these results not only age had an influence, but nutrition also, in its bearing upon the general health and free circulation.

Nevertheless, it must not be thought that every muscle divided in amputation must of necessity become atrophied and fatty. Sometimes when thus deprived of one point of attachment the muscle soon begins to acquire others. It fixes itself upon the new formations of bone, or finds a point of support in the common fibrous tissue to which itself contributes a portion, and, in as far as its nerves are not destroyed and its functions are called into action, we find its volume and structure preserved. We do not state this upon hypothesis; five of our observations demonstrated the truth of the assertion.

We need not add more upon fatty degeneration, as it has been studied for a long time, and is now well understood.

*State of the Vessels.*—Many and very important works have been published on the cicatrization of vessels cut in continuity, having for their special object the mode of occlusion of arteries. The solution of a problem in pathological anatomy has not been so much sought for as the surest way to obtain a closure of the vessel. Ligation continues still the usual practice in amputations.

Our observations have been confined to stumps long after cicatrization had finished, and therefore we will now discuss only the following points:—

Does the fibrinous clot-plug continue indefinitely in the vessel?

Is the clot susceptible of becoming organized and of establishing with the vascular wall intimate adhesions, fully organized and traversed by vessels?

Can the clot-plug be completely absorbed; and in such case can the walls of the vessel unite so as to form only a fibrous cord?

Does the arterial wall become thin, so as to resemble that of a vein?

M. Hutin, in his remarkable work, records the persistence of the clot-plug, filling the cavity of the vessel, long years after the amputation. This we have met with nine times in thirty-two cases, or one more than a quarter part. In all these cases the clot was fibrinous, whitish, firm, and formed in concentric layers—variable in dimensions and extent. It was sometimes prolonged up to the first important collateral from the very extremity of the artery; at others no collateral marked its upper limit, while below it was lost in the walls of the artery so closely united as to transform the vessel into a simple fibrous cord.

In none of these cases did the clot-plug present any traces of organization. Microscopic examination showed only fibrin more or less disaggregated, never any vessels. Sometimes the adhesions to the arterial walls were very intimate, but more often the clot separated readily.

The absorption of the clot-plug, with the intimate and complete fusion of the walls of the artery, which was thus transformed into a simple fibrous cord, was met with more frequently. We noticed this in fourteen, or almost half our cases. This transformation varied greatly. The adhesions were rarely abrupt; and the vessel seldom maintained its normal calibre upwards. Accompanied by a vein still more feeble than itself, and proportioned to the parts to be nourished, the artery at once began to lose its dimensions. As it approached the stump it contracted, sometimes gradually, sometimes suddenly after having given off an important collateral. This diminution of calibre was noted fifteen times in thirty-two cases, and this, too, where the anatomical situation permitted the easiest demonstration of its reality. It was thus that in amputation of the arm at the upper third, and in disarticulations of the shoulder, the axillary artery, after having furnished scapular branches, shrivelled and became a true arteriole. There was no further occasion for it.

In one instance only have we noticed the vascular wall thinned, resembling that of a vein. Oftener, four times, we have found it notably thickened.

Besides these two modes of termination, sometimes the artery continued permeable even to its extremity, without clot-plug or fibrous terminal cord. Then the calibre either gradually diminished to the point of closure, or, on the contrary, remained unchanged, presenting the appearance a vessel should have immediately after ligation, i.e., a true *cul-de-sac*. When the latter occurred, a cluster of arterioles was not infrequently found arising from this *cul-de-sac* to spread themselves into the common fibrous tissue. We have met with this permeability eight times, and in half of these cases the calibre of the vessel remained unaltered to its extremity.

With M. Hutin, we have very seldom met with a fibrous cord which prolonged the artery to the cutaneous cicatrix, or that which M. Notta thought to be an indolular band, corresponding to the former passage of the ligature of the vessel. We have always found the artery itself terminating at a distance from the cutaneous cicatrix, varying according to the greater or less hindrance to the vessel's retraction. Cut in the middle of the thigh, the artery will retract strongly within its sheath. It preserves its original position only when retained in it by fibrous adhesions.

We have not found atheromatous degeneration when present more frequent or more advanced in the arteries of the amputated member than in other parts.

*State of the Veins.*—Cicatrization of the veins has not been studied with the same care as that of the arteries. The direction of the sanguineous current and the presence of valves opposing its return, render, in fact, venous hemorrhages less frequent than arterial. If a vein is tied, obliteration seems to take place by adhesive phlebitis, forming a clot which is afterwards absorbed. The walls of the vessel then immediately fall together, and are soon completely united. Thus, at least, we have always found it in our investigations.

*State of the Nerves.*—Nerve-anastomosis, maintained by Larrey as a constant fact, and denied by Hutin who saw in it only a simple contact, has never appeared under our observation. Once we saw an internal cutaneous nerve seeming to be confounded by a loop with a median in the same terminal enlargement, but it was only a semblance, a simple juxtaposition of the terminal neuromata of these two nerve-trunks.

Sometimes two nerves in contact were thus commingled in the terminal tumor. Sometimes a whole cluster of nerves were likewise englobed in one neuroma, as was

especially seen in disarticulations of the shoulder. But even in these cases there never was an anastomosis. At one time the separate neuromata were intimately united to form one single mass where each, nevertheless, could be distinguished. At another time these neuromata, although buried in a common adipose tissue, had no connection whatever between themselves. We met with each of these conditions four times in eight amputations, of the arm and at the shoulder-joint.

We may conclude, then, that real nerve-anastomosis is very questionable; that even apparent anastomosis is very rare; and that, for the most part, the nerves have isolated terminations, although their extremities be enclosed in the same fibrous cicatricial tissue.

Larrey first demonstrated the termination of the divided nerves of a stump in a tubercle more or less voluminous and rounded; from which, according to him, nerve-filaments diverged to conduct the animal electricity to the cicatrix.

Now, nerves for which there is no longer any use, present to the naked eye normal dimensions and aspect; and, on section, we almost invariably found them healthy under the microscope. But in a certain number of cases we met with the following state of things:—

On longitudinal section three layers were readily made out:—1, the external, thin and white, formed by the neurilemma, a dense connective tissue; 2, the middle, yellow and often increased by adipose matter as it approached the terminal protuberance, being composed of a very loose connective tissue, with interspaces filled with fat; 3, the central, consisting of a white cord, variable in thickness, and dividing so as to be lost in the terminal bulb. This cord was composed exclusively of unaltered primitive nerve-fibres.

This condition we have only seldom fallen in with. Is it a cadaveric phenomenon, the result of an alteration of a nerve after death? Nothing appeared that could give rise to such a supposition; and there were no peculiarities in the subjects adequate to the solution of the question. The autopsies were made at equal intervals after death. We must add, however, that we have met with this condition only in obese individuals, in stumps loaded with fat, and where the muscles were fatty in the highest degree. It gradually diminished upwards, and entirely disappeared four or five inches above the terminal neuroma.

We find that all authors (Larrey, Hutin,

&c.) lay stress upon the club-like termination of nerve-cords cut in amputation—a result differing from that obtained in experimental nerve-sections, where the central end of the divided nerve is found to retain nearly its normal size to the point of cicatrization.

In concurrence with M. Hutin, we ought to state that this protuberance is not constant. In our examinations it was wanting twice in amputations of the thigh, twice in the leg, once in the arm; and this, too, sufficiently long—five years or more—after the operations.

In all our other cases the nerves have presented these little tumors; variable in development, yet always in proportion to the size of the nerve-trunk. Eight times, according to our records, they were not remarkable; sixteen times, they were voluminous. We shall see presently whether it is possible to explain these variations.

Four times we have met with many such tumors developed along the course of the same nerve near its extremity; once on the tibial saphena, once on the external popliteal sciatic, and twice on the median; without anything to explain the peculiarity.

In general, the protuberance is, as it were, a continuation of the nerve on which it is developed; sometimes, however, it seems to be merely in apposition.

Each nerve appears to have its special and very distinct neuroma. This should be so, necessarily, when their extremities are apart from each other. But the same condition is found also when nerve-trunks are divided at a point where they are brought quite together, as in the axilla, for example. Besides, it is not astonishing that all such neuromata, naturally in contact, should, though distinct, be englobed at their inferior portion in a common fibrous mass connected with the cicatrix. The fibrous bundles of hypertrophied neurilemma adhere, interlace, and form this common portion of the protuberance.

In a single case of disarticulation of the shoulder, we found the extremities of the nerves so lost in the common mass that it was impossible to separate them or to distinguish their particular bulbs.

These protuberances generally had an elongated shape, in the direction of the trunks of the nerves. They varied greatly in size, even on the same nerves, under apparently identical circumstances. In eleven stumps of the thigh, the sciatic terminated seven times in quite large tumors, once in a small one, and three times without enlargement.

Seven patients used, in walking, the padded long peg (*cuissard*), having its principal point of support at the ischium, and being retained in place by a leather belt around the pelvis. In six of these the sciatic bulb was very large. In one there was no terminal nenroma.

The remaining four used crutches. Of these, one had a very large, one a very small, and two no apparent tumor of the sciatic. Almost all the operations dated far back—the most recent as far as 1854–55.

It would seem, then, that the apparatus used in walking had some influence in the production of these swellings; how much we shall soon see, and how it may be understood and explained.

The position of these tumors varied with that of the nerves on which they were situated, and they were greatly modified by their connections with the neighboring parts. When the nerve was in the midst of the celluloso-adipose tissue, loose in surrounding parts, as the sciatic, the axillary plexus, &c., we found the neuromata free also in the fatty mass, and attached only to the cicatrix by the lower extremity. When, on the contrary, the nerves were fixed at the point of division, as, for instance, the radial in the humeral groove, and by external intermuscular aponeurosis, or the external popliteal sciatic at the neck of the fibula, then the terminal protuberance was often found englobed in the fibrous cicatricial tissue, and at times inseparable from it.

These tumors presented to the naked eye a smooth, pearl-white surface, and elastic consistence. Free throughout most of their extent, they were almost always attached to the cicatrix by fibrous prolongations from their inferior extremities. Once only have we found the tumor completely free, without any connection with the fibrous tissue.

So great was their elasticity that it was difficult to cut them with scissors, or even with the scalpel. They presented a rosy-white, cut surface, with yellowish or at times still whiter and glaring patches at the centre and borders, or over the mass. In other respects these tumors were so variable that it is impossible to give a general description applicable to all. Nevertheless two portions could ordinarily be made out:—1, the exterior envelope, the continuation and manifest expansion of the hypertrophied neurilemma, which could be traced onward even into the fibrous cord attached to the cicatrix; 2, the central portion, which appeared to be rather the ex-

pansion of the nerve itself and of its tissue more or less modified.

We have said that the neurilemma spread out disunited bundles over the tumor, to form its external layer. Farther on, these bundles again approached each other, and condensed to form a simple fibrinous cord, which disappeared in the common fibrous tissue. Very rarely, these bundles continued, as it were isolated, even to their union with the cicatrix. But we have never met with the nervous fibrils which Larrey regarded as the conductors of animal electricity, and which M. Hutin has sometimes also observed.

Are these nerve-bulbs, which Cruveilhier described under the name of *traumatic neuromata*, in reality tumors of such a nature? Are they true nerve-tubes in their structure, or simply, as Legouest and A. Guérin thought, the result of hypertrophy of the connective tissue? Let us admit in the first place that in external characteristics, form, color, aspect, consistence, &c., these tumors greatly resembled common neuromata. But they differed from the latter decidedly in the symptoms produced. Spontaneous, sharp, and sometimes insupportable pains are constant attendants on pathological neuromata. In stumps, on the contrary, so far as we have been able to observe them, such pains are rare compared with the frequency of traumatic neuromata. But the histological structure is the same in both, and this settles the question. Microscopic examinations which we practised in almost all these cases, and which MM. Pautet and Villenin kindly repeated, enable us to affirm in all of these tumors the presence of true nerve-tubes.

Two elements concurred to form these bulbs—the compact fibres of connective tissue, and the bundles of nerve-fibres. On the surface of the exterior appeared only fibrous tissue, arising from the hypertrophied neurilemma which enveloped the tumor. The internal part, or the tumor properly so-called, was formed of very dense connective tissue, in which meandered bundles of nerve-fibres, more or less abundant, and more or less in apposition. Infrequent at the periphery, these nerve-bundles became so numerous in the central tract as to suggest a local development of nerve-fibres.

These tumors were, then, true neuromata, as Cruveilhier and Hutin considered them.

We have never seen nerve-fibres pass the limits of the tumor. The ligamentous cords and the loops which attached it to the common fibrous tissue were exclusively formed of bundles of connective tissue, re-united in

one instance, isolated and distinct in another. Even when there was no terminal bulb, the fibrous cord, almost uniformly present, was never composed of anything but connective tissue.

[To be continued.]

## AN AMUSING CHAPTER IN THE NOMENCLATURE OF SKIN DISEASES.

By JAMES C. WHITE, M.D.

No writer has done so much to increase the unfortunate confusion which exists in connection with the nomenclature of cutaneous diseases as Mr. Wilson. For a long time and until a recent period looked upon as the leader in this department of medicine in England and this country, he has never let slip the opportunity of introducing new and of altering old names in his writings. In his latest editions and in the numerous articles published in his *Journal of Cutaneous Medicine*, many of which are the merest twaddle, this propensity to invent long Greek titles, or to hunt up others forgotten for centuries and never used with any definite meaning, amounts almost to a mania. Among the most amusing of these exhibitions, and a fair illustration of his whimsical mutability, is that afforded by the list of names adopted by him from time to time in connection with Psoriasis.

Up to the 4th edition of his work he had called this affection *Lepra*, applying the former, its proper title, to a variety of chronic eczema. In the preface to his 5th edition, published in 1863, and written immediately after an interview with Professor Hebra "amidst the academic groves of Richmond Hill," we find the following change announced:—

"To return to *Hebra*. The term *Lepra*—*der Aussatz* in German—signifies the eruption, the great eruption. It is synonymous with Leprosy, the leprosy, the ancient leprosy, that which has since been called elephantiasis. Therefore let us bestow the term *lepra* where it rightfully belongs, or reject it altogether. The trivial affection which we at present call *lepra* has no single point of comparison with leprosy. We cannot but admit the truth of this argument, and we cannot, also, but recognize in an instant the monstrous absurdity of calling a comparatively insignificant disease by so portentous a name.

"Now, *Hebra* cuts the Gordian knot. Eczema he calls *eczema*; *lepra*, *lepra*; and that very common affection which we at present term *lepra*, he calls *psoriasis*. The

change is simple, the reasons for it important. We cannot do better than adopt it. Moreover, it suits the *spirit of the British bull-dog* to call things by their proper names, and we are too noble in our nature not to recognize and value the intellect of our foreign brethren. The great International Exhibition of 1862 will not have existed in vain, if it have accomplished no more than to enable us to give the proper name to a very common and troublesome disease."

Considering the reputation for tenacity of the canine species here mentioned, it might be presumed that this matter of title was definitely settled, but in the "Student's Book of Cutaneous Medicine," published in 1864, the "intoxication" produced by the "fascinations of his agreeable friend" (Prof. H.), seems to have subsided, for Richmond Hill is ignored, the term Psoriasis being still retained for this form of chronic eczema, while his old Lepra is called Alphos.

In April, 1868, this Gordian knot appears to be still uncut, and a positive reaction has taken place in the temper of the British bull-dog, for in an article on this affection, no longer Alphos but Lepra again, published in the Journal of Cutaneous Medicine at that time, we find the following recantation: "Nothing can be more outrageous than the blunder of calling Lepra vulgaris, Psoriasis: happily it is a foreign blunder; but we trust that there are few amongst us who are so lost to the proper estimation of nationality as to submit blindfold to the foreign yoke. We have no objection to accept the truth at the hands of our foreign brethren, but once and for all we reject their falsehood; and we have a proper disdain for the spirit of *gobe-moucheism*, which is at all times ready to gulp down "omne ignotum pro magnifico."

Later in the same year (October) he calls Psoriasis, Lepra Alphos; and in January, 1869, another alteration is introduced, and the title Lepra græcorum is adopted. In this latter article, a review of Hebra's work, he again says "it would be a serious mistake to confer on Lepra so unsuitable a designation as that of Psoriasis, as is proposed by our Austrian colleague. We trust that our countrymen will agree with us in our objection, and resist an attempt at the alteration of our nomenclature, which is pressed upon us inconsiderately, and with an authority which we think it absolutely necessary to resist." To this a writer in the *Edinburgh Medical Journal* of March, if we mistake not, the well-known author of the best works on skin diseases published in Great Britain, replies:—"And but small

excitement do we feel in the approaching contest which Mr. Wilson announces as about to take place between himself, a self-elected champion of Britain, and Hebra, as the supporter of the honor of Germany; notwithstanding the flourish of trumpets with which Mr. Wilson accepts the fancied challenge, and calls upon all interested to form a ring, and be judges of the fairness of the strategy. For it is just possible that the personal appearance of his German opponent in the field may once again be sufficient for victory, and enable him to return to his country singing the exulting psalm of *veni, vidi, vici*."

What change of title the next quarterly issue of his Journal will bring with it, time will show.

## Hospital Reports.

---

### BOSTON CITY HOSPITAL.

Reported by FRANK W. DRAPER, M.D., House Surgeon.

*Aneurism of the Innominate Artery.* (Service of Dr. CHEEVER.)—Fourteen weeks before his entrance to the Hospital, the patient, a strong, well-built, perfectly healthy laboring man, aged 38 years, first noticed pain between the scapulæ, with continuous cough. The symptoms were exacerbated by unusual exertion, and after three weeks he was admitted to the Mass. General Hospital to be treated for his cough. Seven weeks of treatment in great measure relieved this symptom. At the time of his discharge, nothing abnormal had been noticed about the heart or the adjacent arteries. Meanwhile the pain in the back continued, and a sensation of cold in the shoulders and down the arm, and of numbness in the right arm, were superadded.

Very soon after his discharge from the Hospital, and four weeks before his entrance to the City Hospital, his attention was first called to a pulsating tumor near the upper border of the sternum and a little to the right of the median line. The cough recurred, and exertion induced various uncomfortable sensations, referred to the shoulder, the arm and the seat of the tumor, and three weeks before he appeared at the City Hospital, the tumor had so far developed as to press on the recurrent laryngeal nerve sufficiently to cause hoarseness.

He entered the Hospital with the following appearances and symptoms. On exa-

mination, the right side of the neck was observed to be markedly enlarged. The sterno-mastoid muscle was thrown outward. The general aspect of the patient tended toward lividity. Just within the right sterno-clavicular articulation could be felt a pulsating tumor, which rose above the articulation and presented a regularly ovoid outline, its apparent size being that of a goose-egg. The pulsations were strong, and the sac appeared thin and superficial. The impulse was transmitted in a marked degree to the adjacent regions. The right external carotid artery could hardly be felt, and it was doubtful whether it was determined at all; the left pulsated normally. There was no perceptible difference in the pulsation of the two radial arteries. Auscultation discovered nothing abnormal in the cardiac sounds or in the aorta. There was a well-marked bruit in the tumor. The patient was harassed by a cough, and there were abundant moist rales in both chests. The hoarseness was a very marked symptom, and was accompanied by wheezy, croupy cough, like that after tracheotomy.

The general condition of the patient had not suffered materially. The appetite was good; pulse 96, regular.

During the week following his entrance all the symptoms were aggravated, and the physical appearances became daily more grave. A consultation of the surgeons determined the tumor to be an aneurism of the innominate artery, and that the question of operative interference should be left to the decision of the patient himself.

The decision of the patient being in favor of an operation, he was etherized in the recumbent position, the process being conducted slowly and with difficulty, on account of the increasing dyspnoea. The lividity, which at the outset was considerable, was much increased. Etherization occurred after twenty minutes, and  $\frac{3}{4}$  viij. of ether were used. When the patient was placed on the operating table he was breathing very laboriously, and the face had assumed a dark-blue aspect. The ether was suspended and not resumed, and there was subsequently, until the end, no reaction, the patient continuing in a comatose state, breathing heavily and at times with the greatest difficulty.

The operation was with a view to the ligation of the right common carotid artery and the right subclavian. The first incision was made for the tying of the former vessel, in the apex of the superior carotid triangle. From the first cut, the venous

hæmorrhage was excessive, welling up in the wound in spite of vigorous sponging, each new cut causing fresh bleeding. The operation was conducted by feeling alone. The edge of the sterno-mastoid was reached and lifted, but the finger failed to detect any pulsation. The attempt to ligate here was abandoned for the time being, as it was hoped that after the subclavian was tied pulsation might be evident in the carotid.

The incision was next made for the ligation of the subclavian in its third portion. The same difficulty was experienced with the profuse venous bleeding as before. The blood was now fully carbonized, and welled up in a continuous inky stream. No landmarks were seen, and the operation was carried on by careful picking with the director. The artery was reached and held under the finger. The subclavian aneurism needle was passed from before backwards and below upwards, and as it emerged from under the artery a smart gush of venous blood filled the wound, at once obscuring everything and causing the patient to gasp, and the pulse to fall so low that it could not be felt. Stimulation caused partial reaction.

Efforts were now directed towards securing the subclavian vein, which had probably been ruptured through its thinned and dilated wall, by the passage of the needle, close to its junction with the innominate. The wound was enlarged in all directions; the sterno-mastoid was cut and reflected, and the incision carried on until the aneurismal sac was exposed, and as much room gained as possible with safety. A section of the clavicle was made with a Hey's saw, and a portion of the middle third, an inch and a half long, removed.

Meanwhile the patient's condition was becoming increasingly alarming. The dyspnoea had developed to the gasping respiration of the moribund state; at times there was complete suspension of both pulse and respiration. The blood was of the color of prune-juice. The face was dark blue. There was no consciousness. The pupils were partially dilated. The extremities were cold.

Further attempts were now desisted from, as the patient was plainly *in articulo mortis*. The wound was plugged, and warmth and stimulants were applied. Death occurred two hours subsequently.

*Post-mortem Appearances.*—The heart, arch of the aorta and adjacent vessels, with the aneurismal sac, were hastily removed through the wound in the neck. The heart was healthy, and the arch of the aorta and

the left carotid and subclavian contained nothing abnormal. The aneurismal sac was as large as an orange, and was confined to the innominate artery; its cavity contained layers of firm and of flaky fibrin, but the contents were chiefly blood. The openings into the aorta and the carotid and subclavian were normal. The vertebral artery was plugged with a firm clot from its orifice as far up as the section reached (two inches). The trachea had been pushed to the left side, and was compressed laterally, so that it had assumed a triangular shape, its calibre being considerably lessened. The inner surface of the manubrium and of the adjacent inner eighth of the clavicle were eroded and roughened. The lesions of the venous trunks could not be determined, on account of the necessary haste in the removal of the specimen. Neither was the carotid dissected up high enough to determine the fact of its occlusion.

The condition of the sac, its being wholly confined to the innominate, and the plugging of some of the trunks issuing from it, render it probable that an early operation by simultaneous distal ligature of the subclavian and carotid arteries might have so far suspended the circulation in the sac as to have led to a cure.

Death was due to asphyxia, and not to hæmorrhage. The quantity of blood lost was moderate, and wholly venous. It ought rather to have relieved the venous congestion of the brain. When we reflect upon the interruption to the aëration and circulation of the venous blood, we need not be surprised at the patient's condition and death. The trachea was compressed, and the recurrent nerve so stretched that one half the larynx was paralyzed. At the same time, the vertebral artery was plugged, and the carotid diminished and probably occluded. The two great return trunks, the venæ innominatæ, passed between the aneurism and the sternum to form the superior vena cava, and were compressed by every pulsation in the sac, thus favoring venous congestion of the brain, and also dilating the jugulars and subclavian vein so enormously as to lead to great capillary venous hæmorrhage, and to rupture of the subclavian vein.

We are informed by the official accounts, which have just been published, that during the last twelve months the number of horses slain in Paris amounts to 2,400; five per cent. have been employed in making sausages, &c.

VOL. III.—No. 14a

## Bibliographical Notices.

*A Conspectus of the Medical Sciences: comprising Manuals of Anatomy, Physiology, Chemistry, Materia Medica, Practice of Medicine, Surgery and Obstetrics. For the use of Students.* By HENRY HARTSHORNE, A.M., M.D., &c. &c. With 310 Illustrations. Philadelphia: Henry C. Lea. 1869. 12mo. Pp. 1002.

This book seems to us hardly worthy of its author. To the "student" it may afford help in "cramming" for an examination. Great care is said to have been taken to render the book *throughout* accurate. Perhaps the attempt has succeeded.

## Medical and Surgical Journal.

BOSTON: THURSDAY, MAY 6, 1869.

### TRICHINA SPIRALIS.

WE presume that no apology on our part is needed for devoting a large space here to giving as an extract from the *Medical Record* the following entire article of Professor John C. Dalton on *Trichina Spiralis*. If the motto *multum in parvo* were ever applicable, it is merited by this monograph.

We have to express our great indebtedness to Dr. Dalton for his good offices in endorsing over to Messrs. Wm. Wood & Co.—the publishers of the *Record*—our solicitations for a supply of the excellent plates which accompany the monograph; and to those gentlemen for their liberality in furnishing us the plates at cost. The illustrations are steel engravings, photographed from original drawings made by Dr. Dalton.

*Trichina Spiralis: A Lecture Delivered at the College of Physicians and Surgeons, New York, Feb. 20, 1869.* By JOHN C. DALTON, M.D., Professor of Physiology and Microscopic Anatomy.

GENTLEMEN:—The subject of Trichinosis, to which our attention will be directed to-day, is remarkably interesting in three points of view. First of all, it is a disease of extreme importance with regard to its possible frequency, the fatality which it sometimes manifests, and the ease with which,

at any time, it may show itself in a community where it has been previously unknown; at the same time it is a preventable disease; and in the third place, it is especially interesting as an instance of a malady which has been discovered, so to speak, suddenly, within a comparatively short period, although undoubtedly it has existed unrecognized from time immemorial.

Trichinosis, as you are all now aware, is a disease produced by the infection of the muscular system by a minute parasite, which has received the name of *trichina spiralis*. The existence of trichina spiralis in the muscles of the human subject, has been known for over thirty-five years. As early as 1832, little bodies were discovered in human muscle, which upon examination were found to consist of ovoid sacs, and a few years later it was found that each one of these sacs contained a minute round worm coiled spirally upon itself. This discovery was first made in the muscles of a hospital patient. In that case it was found that the trichinae were exceedingly numerous and scattered throughout the body, in the substance of the voluntary muscles. Since that time they have been noticed, in many instances, in persons who have died from accidental causes, from pneumonia, from phthisis, and various other affections: from diseases, in a word, which would appear to be entirely disconnected with the existence of the parasites; so that notwithstanding the great abundance of the parasites, medical men were forced to the conclusion that they exerted no deleterious influences whatever upon the subjects inhabited by them.

I have here a specimen which I took myself from the human subject, some ten years ago. It is the rectus femoris muscle, and, like the other voluntary muscles in this case, it is full of these parasites. You will see here the regular appearance of the trichinae as they are usually seen, and as they were exclusively known previous to about the year 1855. Look at this muscle very carefully; you will find, just visible to the naked eye, minute ovoid bodies situated between the muscular fibres, having an opaque envelope and a transparent, but apparently dark-colored, centre. On dissecting out these bodies with needles, it is found, as I have said, that they consist of an ovoid sac, and inside this sac the worm lies, spirally coiled. This is the old encysted trichina, such as you see in this drawing. (*Vide* Plate, Fig. 1.)

Between the fibres of the muscle, and lying parallel with them, is the ovoid sac, somewhat pointed and yet slightly rounded

at its two ends, and swollen in the middle, where the worm is coiled up. Now the trichina is coiled in such a manner inside the sac, as to make about two turns and a half upon itself. One extremity of the worm is blunt and rounded, the other is more pointed, and the two lie so near each other that half a turn more would bring them together. These bodies, although so minute, are yet visible to the naked eye on close examination in such specimens as this; because, as you readily find under the microscope, they are partly solidified by a calcareous deposit in the cavity of the sac. This deposit is of a gritty and almost crystalline texture, brittle, breaking upon firm pressure, and is composed, probably, of phosphate of lime, slowly deposited, so as to give to the extremities of the sac an opaque appearance and a very firm consistency.

This is the condition in which the trichina presented itself in all specimens brought to the observation of medical men, for some twenty-five years after its first discovery. They were cases of old, encysted trichinae. All that was known about them was that they were encysted, that they did not exhibit any distinct sexual apparatus, and they did not appear to produce any distinct symptoms by their presence in the human organism.

But between the years 1850 and 1860, certain experimenters in Germany undertook to examine the natural history of this parasite more closely. They did so by administering portions of muscle infected with it to the lower animals; and they found—especially Leuckart, who was the most successful in these investigations—that the worms, apparently so insignificant in size, and so incomplete in development so long as retained in the muscular system, become further developed when introduced into the intestine of another animal. After a short time the sexual apparatus appears, copulation takes place, the female produces living young, and these young penetrate finally into the muscular tissue of the second animal, and there domicile themselves for an indefinite time. In this way somewhat more definite ideas were acquired with regard to the natural history of the worm, as found in the inferior animals. By a continuation of these experiments, it was found that this infection of the muscular system with trichina may show itself in the pig, the cat, the rat, the mouse, the rabbit, and, I believe, one or two other species of the inferior animals.

So far, nothing more had been learned

with regard to trichinosis as constituting a disease in the human subject. The new era in this respect opened with the year 1860. At that time an epidemic of trichinosis occurred in Germany. The members of a family living in Dresden were taken sick with symptoms similar to those of acute rheumatism, mingled with those of typhoid fever. One of them, a servant-girl, died, and on examination it was found that her muscles were filled with trichinae. The attending physician and Professor Virchow tried the experiment of administering the trichinous muscles to this rabbit, and found that the rabbit became infected with the parasite, and died in about four weeks' time. The infected tissues of a rabbit were administered to a second, which became infected in the same manner, and died, like the first, in about four weeks. Finally, a third rabbit was fed with the flesh of the second, with a similar result. These experiments show that the disease, as it exists in the human subject, may be transmitted to the lower animals; that it may be transmitted indefinitely from one animal to another, the parasites passing alternately from the intestines to the muscular system, and again from the muscular system to the intestines. These are the general outlines of the origin and course of the disease known as trichinosis.

Now let us see what are the details of the anatomical structure and physiological development of the worm itself.

I have said that, as you examine the trichinae in those cases where they have existed in the muscles for an indefinite period, where they have become encysted, and the cavity of the cyst has been invaded by calcareous deposit, it is not easy to make out their anatomical structure. But in cases where the disease is recent, and particularly where it can be traced to the recent use of trichinous flesh as food, the anatomy of the worm can be made out with more distinctness. Such a case happened in this city about five years ago. Some sailors, on board ship, were taken sick while in port with symptoms resembling those noticed in the Dresden family, similar to those of typhoid fever and acute rheumatism combined. It was found that the disease originated, in their cases, from eating raw pork or bacon. About the same time other cases of the disease became developed in persons living permanently in the city; and in these cases the difficulty could be traced to the use of ham imperfectly cooked.

A portion of this ham came into my possession, and in examining it, I found not

only that the meat was trichinous, but also that the parasites were in a decidedly different condition from that which they exhibit in cases of long standing. The first peculiarity was that the cysts in which the worms were contained, instead of having definite and rounded ends, gradually tapered off into long and slender prolongations, the extremities of which could not be reached, being entangled in an intricate manner with the muscular fibres. In these drawings you see represented the cysts containing the trichinae, as found in the ham. (Fig. 2.) In this case the cyst is evidently a hollow, fusiform tube, consisting of a transparent and structureless, but well-developed, membrane, containing the worm coiled up, as you see. From the two extremities of this fusiform cyst run off the prolongations. It is very important to ascertain exactly the structure of these prolongations. It is evident that they are tubular, and that their cavity is nearly continuous with that of the sac containing the worm. Not quite so, however, for it can be seen that a membranous partition runs across where the prolongations begin, so that the worm is enclosed in a distinct cavity; and that the prolongations are tubes of much smaller calibre, but were apparently at some previous time connected with the central cavity. Now this central cavity contains a transparent fluid; the worm is, therefore, lying free in the interior of the sac, not connected with its membranous walls; this can be demonstrated by breaking open the sac by a slight pressure between the glass plates. It ruptures, and discharges the worm, which escapes in such a manner as to show that it lay before perfectly free within the cavity of the sac. (Fig. 3.) The worm still remains coiled up, after its escape, and you will usually find much difficulty in uncoiling it sufficiently to examine its structure. No operation in microscopic anatomy requires more patience than this; for its firm folds must be unwound without rupturing any of its parts, in such a manner as to give you a fair view from one extremity to the other. (Fig. 4.) This done, the trichina, at this stage of development, is found to be a worm one twenty-eighth of an inch in length; its anterior extremity or head is tapering and pointed; the body very gradually enlarges as you pass from the anterior extremity towards the middle, and about the middle acquires its greatest diameter, which it retains throughout the rest of its extent, terminating posteriorly in a round, blunted extremity. The alimentary canal runs longi-

indinally throughout the whole length of the worm, there being a mouth at the anterior or pointed extremity, and an anus at the posterior or rounded end. About the junction of the middle with the posterior third of the parasite, the calibre of the alimentary canal suddenly contracts, then enlarges again, and afterward remains reduced to about one-third its original size. The only other organ visible at this time, is one which occupies, together with the alimentary canal, the posterior third of the worm; an organ apparently tubular in character, rounded at either end, and filled with rather large and tolerably well-defined cellular bodies. This evidently is the sexual apparatus, such as it exists at this time.

The characters which I have given are sufficient to define the encysted trichina as taken from the muscles. Suppose now a portion of muscular flesh, filled with trichinae in this condition, be taken as food by the human subject or administered to one of the lower animals. On arriving in the small intestine, the worms are found to be perfectly free, for the muscular tissues in which they were imbedded, as well as the cysts in which they were contained, are digested in the stomach, so that within twenty-four or forty-eight hours you find an abundance of free trichinae in the cavity of the duodenum. At once they begin to increase in size, so much so that very soon, usually by the fourth or fifth day, they have become three or four times as large as before. They have now arrived at the adult condition. At the same time the sexual apparatus, before so incomplete, has become perfect, and the copulation of the sexes takes place. I have myself, on several occasions, found in the intestine of the rabbit the two sexes in copulation, the male fastened upon the female at the orifice of the generative apparatus. The eggs having been impregnated, as the animal is viviparous, the female soon becomes full of the young brood.

In this drawing you see these parts as I have just described them. (Fig. 5.) Instead of the intestine now taking up the whole of the anterior two-thirds of the body, and a great part of the posterior third, you find that the sexual apparatus is by far the most prominent organ in the interior of the body of the female; and as soon as the young have arrived at the period of development here represented, they begin to move forward to the terminal duct of the generative apparatus. This can now be seen very clearly, running from the ovary forward to a point quite near the anterior extremity of the worm. The young are

very numerous. I do not know that it has been calculated how many a single female is capable of producing, but they are probably very numerous. The young, discharged in this way into the cavity of the small intestine, begin to penetrate through its mucous membrane, by a boring process, passing undoubtedly through the entire thickness of the intestinal walls. This causes a great deal of irritation, which is the first symptom of trichinosis. It is usually sufficient to produce a considerable degree of pain and not unfrequently a smart attack of diarrhoea.

After passing through the walls of the intestine, the worms disperse in every direction, and from that time you begin to find them in the muscular tissue throughout the body. There they domicile themselves, and, within a fortnight after the symptoms have begun to manifest themselves in the human subject, you will find them almost everywhere, scattered throughout the voluntary muscles. They are still very small, having increased but little in size during their transit, so that when they first arrive in the muscular tissue they are not more than about 1-140th or 1-120th of an inch in length. They soon, however, become encysted, and then increase very considerably in size. At first, however, they are not enclosed in distinct sacs, but are found contained in the interior of long tubes.

We have already seen that, although the encysted trichina is contained in a sac or cavity of its own, this sac is often connected with prolongations running out from each extremity; and in the human muscle, within the first fortnight of infection, the young worms are found contained in swollen tubes. This is the condition of the worm as it was found in the muscles of the human subject on the thirteenth day of illness, in a case which I had the opportunity of examining. The worm, you see, is not free, but is contained in the interior of a tube, swollen or fusiform at the point where the worm lies partly coiled up. The worm is not stationary at this time, but by gentle pressure can be made to move from one end to the other of the swollen portion of the tube. By about the end of the first fortnight its coils assume a considerable degree of regularity, and the worm then reaches that condition which has given it its name of *trichina spiralis*.

We have now described the worm as domiciled in the muscular tissue. The next question is, how did it get there, and what is the nature of this tube which it now inhabits, and which is hereafter to become its

cyst? These are points with regard to which some doubt still remains. Most of the German observers are agreed that this tube is a muscular fibre; they believe the worm passes from the intestine to the remotest regions of the body by boring its way through the intermuscular cellular substance; and that if examined on its first arrival there, it is perfectly free; that it then penetrates the substance of the muscular fibre, producing atrophy and degeneration of its substance, until the fibre becomes converted into the tube, with prolongations which I have described. On the other hand, it is possible that the worm, instead of working its way through the intermuscular cellular tissue, may also be transported by the circulation; for if it can bore through the walls of the intestine, it can, of course, also penetrate the bloodvessels, and it might thus finally reach the left side of the heart, and be sent with the current of the circulation to every part of the body. However, it is certain that the young trichinæ arrive at the muscular tissue, either by working their way through the intervening cellular tissue or by distribution by the bloodvessels. They very soon present themselves in the interior of these swollen tubes, which may be either capillary vessels that have become plugged, by coagulation of the blood, or by deposit of the exuded material excited by the presence of the worm; or may be muscular fibres that have undergone degeneration and atrophy from its presence. Soon the tube containing the parasite suffers a further alteration. An exudation takes place around the worm, so that that part of the tube containing it is shut off from the rest; and the remainder of the tube becomes atrophied into slender, tapering prolongations. After some years these also entirely disappear, and you see only an ovoid sac without prolongations; and finally you may have the cavity of the cyst invaded by a calcareous deposit, as I have already described—the last peculiarity of the degenerated cyst.

Now all these changes in the history of the trichina have been seen in the human subject: the development of the young in the body of the female; their discharge from the mother's body into the intestine; their penetration of the walls of the intestine and dispersion to the muscular tissue throughout the body; their domiciliation in the interior of the tubular cavities, and the change of the tubular cavities into ovoid cysts; the calcification of these cysts; and the quiescent and dormant condition of the worms as the result.

Now to what symptoms does this accident give rise? As I have already said, within the first ten days there is irritation of the intestines. In some instances this irritation is very great; and the greater it is, the more favorable the prognosis, as a general rule. After eating trichinous flesh, the patient generally begins to suffer within the first week, sometimes within two days. Now, if the irritation of the intestine be extreme, so that frequent and abundant evacuations are produced, the chances are very great that all, or nearly all, of the parasites will be discharged from the intestine. If so, the patient is safe. But if the irritation be not very marked, time is allowed for the young trichinæ to penetrate the intestinal walls, and enter the muscular tissue—from the end of the first to the end of the second week. This is the most dangerous period, the second stage of the disease. There is general pain and soreness, and œdematous swelling throughout the muscular system. At the same time, typhoid symptoms manifest themselves; the patient is debilitated, his pulse rapid, skin hot, tongue and lips dry, and his general appearance closely resembles that of a patient with typhoid fever.

The passage of the worms into the muscular tissue, and the changes taking place there, are very apt to produce symptoms which result in the patient's death at or before the end of the fourth week. By that time the worms have become completely encysted, and after this the symptoms of irritation begin to disappear. The muscular system becomes habituated, as it were, to the presence of the parasite; and after a while the symptoms all subside; the patient can move his limbs as before, and then considers himself as entirely recovered.

How long may the worms remain in this quiescent condition in the interior of the muscular system. In 1863, Prof. Langenbeck, of Berlin, was operating upon a patient for a tumor of the neck, situated upon the surface of the sterno-mastoid muscle; in dissecting it off, the fibres of this muscle were disclosed, and it was noticed that their surface was covered with minute white specks. These attracted so much attention that a portion was excised and submitted to the microscope, when the specks were found to be encysted trichinæ. After the patient's recovery, minute inquiries were made to ascertain at what time he had become infected. The result was that no such attack could be traced to a period less remote than eighteen years before. At

that time, viz., in 1845, the patient, with several associates, was serving upon a committee of inspection of the public schools. After the inspection in a certain district, the committee partook at the village inn of a lunch, consisting, in part, of ham. Very soon after, all the members of the committee were taken sick with symptoms similar to those we now know to be attributable to trichinosis. Two of them died, and the symptoms of poisoning were so marked that the innkeeper was arrested and held under this charge for a considerable time. Although, finally, the circumstances were not found sufficient for his conviction of the crime, yet they were considered as so much against him, and the prejudices of the community were so excited in consequence, that he was obliged at last to leave the place. On going over all the history of the case, so far as it could be ascertained at that time, it left an undoubted impression on the minds of the medical men who made the investigation, that at the time before mentioned, viz., in 1845, the members of the committee were infected with trichinae from the ham used for their lunch; that two of them had died in consequence; and that Prof. Langenbeck's patient had recovered, and the worms remained encysted for eighteen years afterwards. How much longer they may thus remain I do not know, but I see no reason why they should not last for the remainder of the patient's life. They produce in this condition no interference with the health, and hardly seem to interfere even with the vigor of the muscles.

This was the condition in which the trichinae were nearly always found, prior to the year 1850, and from this fact it was supposed that the trichina was a harmless parasite. Such are the chief circumstances connected with the physiological history of the worm.

There still remains one question of a very important nature—How great is the liability of the community at the present time to be infected, and what measures can be taken to prevent it?

The pig seems to be the animal naturally the most liable to trichinosis. He is certainly more liable to this disease than any other animal used for food, neither the sheep nor the ox being subject to it. It has been found in this country, by investigations in Chicago in 1866, that of all the pigs brought to market in that city, one in fifty is infected with trichina. This shows that we are all in danger of becoming infected by the use of pork, unless measures are taken, in preparing the meat, to

destroy the vitality of the worms. Smoking and salting will not do this effectually. Only thorough cooking is to be relied on as a safeguard. It is remarkable that most, if not all of the cases of trichinosis in this country, thus far, have occurred among the Germans. This is because they have the habit, not otherwise common here, of eating ham, sausages, and even sometimes fresh pork, nearly or quite in the uncooked state. To kill the worms the ham must not only be salted and smoked, it must be cooked, and cooked thoroughly. Now, if you bear in mind that one pig in fifty is infected with trichina, you will perhaps think many times before putting between your lips a piece of pork, or ham, or sausage in the raw state; you will be certain that it is cooked; and not only that, but thoroughly cooked. One of the worst cases of trichinosis that has come under my observation was caused by eating pork chops which were rare or slightly underdone. Now, these chops were probably well enough cooked on the outside; but on the inside they were red and juicy, and the danger was precisely the same as if the patient had taken the meat entirely raw. In order to destroy the vitality of the trichina, the meat should be subjected to a temperature of 212° F. Now, if you boil a ham for half an hour, or even an hour, you do not necessarily subject all parts of it to this temperature. In the central parts of the ham the temperature will not rise to that point unless the boiling has been long continued. I speak of this particularly, as it is a very important matter. A temperature of less than 160° F. does not destroy the trichina. As shown by direct experiment, therefore, a piece of trichinous meat, any part of which has not been raised to or above this point, is just as dangerous as if it were taken in the raw state.

These are the chief points of importance in regard to the trichina and trichinosis. The disease is fatal enough, frequent enough, and revolting enough to induce us to take all possible measures to prevent it, and I do not think anything is sufficient for this but a personal examination of every piece of pork, ham, bacon, or sausage used as food, to see that every part of it has been subjected to a thorough cooking process.

One other point still I should like to speak of. We have seen that the disease shows itself occasionally in the human subject, but very frequently in the pig. Now, how is it, under these circumstances, that the continuance of the species of *trichina spiralis* is provided for by nature? We

have here an animal that arrives at maturity in the intestine of the human subject. In that situation the female bears living young in consequence of the individual having eaten pork filled with the encysted and quiescent trichinae. So long as these remain encysted and quiescent in the pig's muscles, they remain practically undeveloped and practically sexless. This flesh is eaten by the human subject. In the intestines of the human subject the worms are set free, the females are impregnated and bear young, and these scatter themselves throughout the body. Now, when these young have, in their turn, in the human subject arrived at the period of quiescence, how are they ever to get back to the intestine of a living animal, and so become capable of continuing their species?

I presume that the mode by which the race is continued is this: Suppose we start with the pig infected with quiescent and sexless trichina. This pig is butchered. You know that butchering establishments are the abundant resort of rats, which feed upon the refuse scraps of meat, and of course these after a time become infected with trichina. The worms are developed in the intestine of the rat, and produce living young. These not only infect the muscular system of the rat, but they are also discharged with the feces. These feces become mingled with the food of the pig—an animal, as we know, not very fastidious with regard to his food, and consequently subject to several parasitic diseases—and thus the round of development of the trichina is completed. Again, its perpetuation is provided for by a similar round between the cat and the mouse. The mouse becomes infected by feeding upon refuse meat, and the cat by devouring the mouse or rat. We have, therefore, the natural history of the animal, embracing in each case two different phases, in one of which it undergoes an active development, in the interior of the intestine, while in the other it assumes the quiescent form, becoming encysted in the substance of the muscular system.

There are other points of considerable interest with regard to the rapidity with which the human subject may be infected, the great number of persons who may become infected by eating the product of a single slaughtered animal, and the degree of fatality attending the disease. Enough, however, is known to convince us that the affection is a very frequent one, and liable to be exceedingly fatal, or if not fatal, to produce prolonged and exhausting disease.

Much would be effected if all pork offered for sale in the market could be subjected to inspection, and this has been done in some parts of Germany; pork being liable to infection not only with trichina, but also with cysticercus, producing tapeworm in the human subject. Such inspection would undoubtedly prove very useful. Still it would not afford complete protection, unless carried out with an amount of detail which would in all probability prove practically unattainable. The only absolute protection, therefore, must be that exercised by the individual for himself. He must see that he never uses for food any kind or preparation of pork in any form not so thoroughly cooked as to destroy every possible vestige of parasitic life.

**AURICULAR HÆMATOMA OF THE INSANE.**—The *Gazette Hebdomadaire, &c.*, adds to a previous report of one of Prof. Brown-Séquard's communications to the Academy of Medicine, that that gentleman compared the *auricular hæmatoma of the insane* to the hæmorrhage into the tissues of the ear produced by his artificial lesions of the *corpora restiformia*.

**REPRODUCTION OF LOST MEMBERS.**—The same journal gives a note from M. Philippeaux, in which from certain new experiments he draws the conclusion that, as a general law, among vertebrate animals at least, an organ entirely removed can never be replaced—that when an organ is regenerated the basilar portion has not been removed.

**SUBCUTANEOUS MEDICATION FOR SYPHILIS.**—Dr. Max Van-Mons has reported in the Brussels Academy five cases of secondary syphilis, with indurated chancres, treated by the subcutaneous injection of calomel. Three of the cases received two or three injections each (quantity not stated) at intervals of about twelve days. At the time of writing, these were nearly or quite cured, after the lapse of 37, 20, 19 days respectively; and the remaining two cases, which had each received one injection, only eight days previously, were notably improved. If this discovery is verified, it will prove one of the most important ever made in regard to the treatment of syphilis.—*Wiener Med. Wochenschrift*, No. 24. D. F. L.

**REMOVAL OF URINARY CALCULI.**—Dr. Paul F. Eve has operated more than one hundred times for the removal of urinary calculi.—*N. Y. Medical Record*.

## Medical Miscellany.

**MIDDLESEX NORTH DISTRICT MEDICAL SOCIETY.**—At the annual meeting of this Society, held in Lowell, April 28th, the following officers were elected for the year ending April 27, 1870: Joel Spalding, of Lowell, *President*. Levi Howard, of Chelmsford, *Vice President*. John H. Gilman, of Lowell, *Secretary*. N. B. Edwards, of North Chelmsford, *Treasurer*. Franklin Nickerson, of Lowell, *Curator and Librarian*. John O. Green, of Lowell, *Commissioner of Trials*. *Standing Committee*.—George E. Pinkham of Lowell, Charles Dutton of Tyngsborough, Moses G. Parker of Lowell. *Councillors*.—Charles A. Savory of Lowell, John C. Bartlett of Chelmsford, Walter Burnham of Lowell, Joel Spalding of Lowell, Nathan Allen of Lowell, Francis C. Plunkett of Lowell. *Censors*.—Nathan Allen of Lowell, Charles A. Savory of Lowell, N. B. Edwards of North Chelmsford, Hanover Dickey of Lowell, Daniel P. Gage of Lowell.

*Delegates to the Convention of the American Medical Association*.—Geo. C. Osgood, George Munroe, David Coggin, Joseph H. Smith, Kirk H. Bancroft, W. H. Leighton.

Was Socrates poisoned by hemlock? Was he poisoned by anything? Was there ever any Socrates, any Homer, any Shakspeare? Well, we have got as far in these investigations as this. The scientific are doubting if hemlock is poisonous; but they do not know whether they mean by hemlock the thing referred to in the classic story. Alas! if boyhood has conned that Greek lesson for nought!

**ACADEMIE DE MEDECINE.**—The place in the Section of Surgical Pathology left vacant by the death of M. Velpeau, has been filled by the election of M. Verneuil.

Dr. H. H. A. BEACH has been appointed Assistant Demonstrator of Anatomy in the Medical School of Harvard University.

In his Tuesday's lecture, Dr. Richardson performed a somewhat remarkable experiment in confirmation of an observation originally made by John Hunter. Hunter observed that if fresh muscle be frozen, in the act of thawing muscular contraction will take place. Dr. Richardson has devised an experiment by which the fact may be audibly and visibly demonstrated. If a freshly denuded muscle be first frozen with ether spray and then immersed in a freezing mixture, it may afterwards be gradually thawed by being held horizontally by a piece of cord over water at 120°. If one end of the cord be made fast in the vessel holding the water and the other end be fastened to the trigger of a pistol, and the temperature of the muscle be then suddenly raised by placing a spirit lamp under the vessel containing the water, and heating it to 125°, the muscle contracts sufficiently quickly and forcibly to fire off the pistol.—*London Medical Times and Gazette*, April 10.

**DANGER OF GIVING STRONG DOSES OF CAMPHOR.**—A case illustrating the above has recently

been brought under the notice of the Société de Médecine et de Pharmacie de Grenoble. An enema consisting of five grammes of camphor dissolved in the yolk of an egg was given to a child three years of age suffering from typhoid fever. Symptoms of poisoning soon manifested themselves—convulsions, lividity of the countenance, stupor, arrest of the urinary secretions, &c. The employment of coffee sufficed to restore the child.—*N. Y. Medical Record*.

**THE DISCOVERY OF A MINUTE FOSSIL HORSE.**—Professor Marsh, of Yale College, has discovered in the tertiary deposits of Nebraska, the minutest fossil horse yet obtained. It is only two feet high, although full grown. This makes the seventeenth species of fossil horse discovered on this continent.—*Ibid*.

**DIABETES CURED BY PEROXIDE OF HYDROGEN.**—Mr. J. J. Bayfield (*British Medical Journal*) reports a case of diabetes cured by peroxide of hydrogen. He commenced with half-drachm doses of the ethereal essence of the peroxide, and gradually increased it to three drachms a day.—*Ibid*.

## MEDICAL DIARY OF THE WEEK.

**MONDAY, 9, A.M.,** Massachusetts General Hospital, Med. Clinic. 9, A.M., City Hospital, Ophthalmic Clinic.

**TUESDAY, 9, A.M.,** City Hospital, Medical Clinic, 10, A.M., Surgical Lecture. 9 to 11, A.M., Boston Dispensary. 9-11, A.M., Massachusetts Eye and Ear Infirmary.

**WEDNESDAY, 10, A.M.,** Massachusetts General Hospital, Surgical Visit. 11 A.M., OPERATIONS.

**THURSDAY, 9 A.M.,** Massachusetts General Hospital, Medical Clinic. 10, A.M., Surgical Lecture.

**FRIDAY, 9, A.M.,** City Hospital, Ophthalmic Clinic; 10, A.M., Surgical Visit; 11, A.M., OPERATIONS. 9 to 11, A.M., Boston Dispensary.

**SATURDAY, 10, A.M.,** Massachusetts General Hospital Surgical Visit; 11, A.M., OPERATIONS.

**TO CORRESPONDENTS.**—The following communications have been received:—Caoutchouc in Skin Diseases—Abuse of Charity Medicine—Review of Wells on the Eye—Review of Pamphlet by Dr. Gautillon—Charity Medicine.

N. B.—If any communication accepted after the date of those announced in last week's issue should be printed in advance of any of them, it will be because it happens to fill a gap in making up a number.

**PAMPHLETS RECEIVED.**—Surgical Cases. By David W. Cheever, M.D., Adjunct Professor of Clinical Surgery in Harvard University; Surgeon to the Boston City Hospital.

**DEATHS IN BOSTON** for the week ending Saturday noon, May 1st, 86. Males, 44—Females, 42.—Alcscs, 1—accident, 1—anemia, 1—apoplexy, 3—disease of the brain, 1—inflammation of the bowels, 1—bronchitis, 3—cancer, 3—consumption, 18—convulsions, 3—diabetes, 1—diarrhea, 1—diphtheria, 1—dropsy, 2—dropsy of the brain, 1—erysipelas, 1—scarlet fever, 12—typhoid fever, 2—infantile disease, 1—disease of the kidneys, 2—inflammation of the lungs, 9—marasmus, 3—old age, 5—paralysis, 3—premature birth, 1—puerperal disease, 2—rheumatism, 1—unknown, 2—whooping cough, 1.

Under 5 years of age, 32—between 5 and 20 years, 6—between 20 and 40 years, 21—between 40 and 60 years, 15—above 60 years, 12. Born in the United States, 60—Ireland, 20—other places, 6.

## Original Communications.

### AN ENORMOUS MASS OF DISEASE, FORMED BY CANCEROUS DEGENERATION OF THE KIDNEY, IN AN INFANT.

By C. F. GEORGE, M.D., of Centerville, Mass.

On the 12th of January, I was called to see the patient, female, aged 17½ mos. Found her pale, considerably emaciated, irritable and restless; sleep disturbed; appetite variable; bowels constipated. Urine apparently natural as to color and quantity; no pain on passing it. In the left hypochondriac region was a tumor, extending from under the ribs downward and forward to within an inch and a half of the umbilicus, attached at its upper extremity and movable at its lower. It seemed about the size of a large goose-egg, was not painful on pressure, and there was no fluctuation. A little bulging of the side; none backward.

The previous history of the case was— whooping cough at three weeks of age; measles at one year; otherwise she was apparently as healthy a child as usual of that age. About the first of last November she was weaned, and from that time the mother dates the first symptoms of failure. These were mainly variable appetite, constipation, irritability and restlessness, with gradual loss of flesh. The mother first discovered the tumor on the 1st of January.

After I saw her, the appetite improved, the bowels became more regular, and she slept better; but still some irritability remained. January 24th, and during my absence, Dr. J. M. Smith was called. The tumor then extended to the umbilicus, and was larger laterally. About this time she had a slight febrile movement, and some difficulty in passing urine, which was scanty and high colored. This passed off in three or four days, and the child seemed about the same as before.

February 10th and 17th, Dr. Pincus saw the case. The child was pale and emaciated; appetite failing; bowels quite regular; urine natural (apparently); tumor in-

creased in size, not fluctuating, but slightly tender.

From this time the appetite continued to fail; bowels became a little constipated; irritability increased; patient restless, and at times seemed to suffer a little pain. Urine freely passed, and without difficulty. Tumor rapidly increased. About the first of March, slight fluctuation in the right side was discovered. Feet, legs and face became œdematous, though at no time was the swelling very great. Still pale (white) and losing flesh. After this she rapidly failed, and died March 12th, of exhaustion (seemingly), and without distress or pain.

On examination, the emaciation was extreme. Abdomen enormously distended; sides bulging out, and somewhat backward. Two or three ounces of fluid in the cavity; and the tumor occupied nearly the whole space, with some slight adhesions of the peritoneum, but not enough to indicate much inflammatory action. The tumor extended from under the left ribs to the brim of the pelvis. The liver, spleen and stomach were pushed upward; and the pancreas and transverse colon were quite firmly attached to the upper extremity of the mass. The descending colon was pushed forward and inward, so that it occupied the median line immediately under the anterior walls of the abdomen. The small intestine was crowded into the right iliac region. The mass was found to be the left kidney; it weighed 5 pounds and 15 ounces when first removed. The bowels were empty. The right kidney seemed natural, as also the liver and spleen. The lymphatic (mesenteric) glands were a little enlarged. On making an opening in the tumor, a considerable quantity of fluid escaped.

*Family History.*—Paternally, the whole family are more or less scrofulous. Maternally, family healthy; no constitutional disease, excepting a "traditional cancer" three generations back.

The diseased mass was carried by Dr. G. to Dr. Pincus, of Hyannis, who sent it to Dr. Jackson in an entire state and perfectly fresh, excepting the puncture made by Dr.

[WHOLE No. 2150.]

G. Dr. J. showed it to the Society for Medical Improvement, and he and Dr. Coolidge gave subsequently the following description:—

"The mass was of an oval form;  $8\frac{1}{4}$  inches in length,  $6\frac{1}{2}$  inches in width, and 5 inches in thickness; weight, 5 lbs.  $3\frac{1}{2}$  oz. Upon one surface there were the remains of the kidney, about two inches in extent; and, including this, was a somewhat defined, oval, superficial patch, about  $6\frac{1}{2}$  inches by  $2\frac{1}{2}$  inches in extent, and that strongly suggested the idea of a connection with the original outline of the organ. Around this patch the surface was lobulated, and radiated in appearance, but upon the opposite surface it was much more even. The irregularity was much more apparent after a fibrous envelop had been stripped off that was quite marked for the most part, and moderately adherent by a lax tissue, though less so to the patch above referred to than to some other parts. Towards the surface where the patch was, and throughout nearly one half of the whole mass, the structure was white, not vascular, had a pearly translucency, and was softer than foetal brain, with an appearance as if it were infiltrated with a ropy fluid. The remainder was much firmer, and evidently contained more or less connective tissue, the softer and firmer portions passing gradually into each other. This last was also stained by blood, and in some parts quite deeply, though no free clots were found. There was also a small serous cyst in this firmer portion. The portion of kidney above referred to was perfectly healthy in appearance; and, on incision, there was found, within, a well-marked pelvis that could be traced for three or four inches, and infundibula arising from it, with portions of the renal substance that had undergone more or less the cancerous transformation. There were also found in distant parts, but upon the surface of the mass only, several small, insulated remains of perfectly healthy renal substance, about three or four lines in diameter.

Under the microscope, the soft substance which constituted so large a part of the disease consisted of innumerable, roundish cells, not varying much in size or form. They had large nuclei, and were embedded in a soft, streaky, ropy mass. At the end of a week, the specimen not having been preserved in any way, the nuclei alone were visible; the substance of the cells having become undistinguishably fused with the mass in which they were."

## TEDIOUS LABOR; INCISION OF OS AND CERVIX UTERI.

By JOHN L. SULLIVAN, M.D., Malden.

Mrs. F. D., aged 25, primipara, well formed, muscular. Labor pains first felt on the evening of 10th inst. When examined, at 9, P.M., of the 11th inst., os was found too small to admit the point of the fore-finger; presentation probably cephalic; pains light, but regular, recurring at intervals of fifteen minutes; passages moist, cool; perinaeum relaxed.

12th, 9, A.M.—Pains all night, preventing sleep; os unchanged. During the day slight, bloody show; membranes ruptured; waters discharged.

11, P.M.—Os dilated so as barely to admit fore-finger; head presenting; pains every five minutes, and severer; patient fatigued and somewhat desponding. Opium (grs. iij.) administered.

13th, 9, A.M.—Slept "by snatches" during night; pains every three or five minutes; slight thirst; no appetite. Warm hip bath, enema per rectum, tartar emetic *ad nauseam*; warm vaginal douche proposed, but objected to.

10, P.M.—Pains increasing; head descending through pelvis, driving uterine neck before it; no farther dilatation; os very rigid. With difficulty, a No. 1 Barnes's dilator introduced and inflated. Pains very severe; dilator removed after an hour. Os dilated to about the size of half a dollar, still rigid; presentation readily diagnosed *r. o. c.* Largest sized dilator introduced, followed by very frequent and severe uterine contractions. Dilator removed in half an hour. Os two inches in diameter; edge like whip-cord.

14th, 1, A.M.—Dilator introduced and fully expanded. Pains violent and almost uninterrupted.

$1\frac{1}{2}$ , A.M.—Dilator removed. No permanent increase in dilatation of os, which seemed to contract like India-rubber on removal of dilator. Patient's condition still good; passages moist; tongue ditto; abdomen not tender; uterine contractions regular and quite forcible. Determined to leave the case to nature until symptoms of constitutional irritation should supervene, rendering further assistance indispensable to the safety of mother or child, or of both.

10, P.M.—No progress towards delivery. Os rigid and undilatable as ever; uterine neck swollen and edematous, pitting deeply on pressure; pains frequent, powerful and agonizing; passages dry and hot; abdomen tender on pressure; tongue dry and

burning; thirst urgent; pulse frequent and hard. One ounce of dark-looking urine drawn by catheter.

It was clear that the safety of mother and child depended upon speedy delivery, and that this could not be effected without assistance. Forceps or incision of the os uteri were the operative measures which suggested themselves. In view of the difficulty of drawing the head through the swollen and unyielding cervix, and the fatal consequences that might ensue from failure in the attempt, the latter alternative, incision of the os, was chosen. The blade of a hernia knife was carefully introduced between the fetal head and the cervix uteri, in the interval between the pains. As soon as the uterine contraction occurred, an incision was made upon the anterior lip through the os and cervix, to the depth of about an inch and a half, care being taken to carry the division of the uterine fibres deep enough to insure the ready passage of the head, and thus obviate in some degree the danger of laceration. This procedure was followed by a discharge of some fluid blood and several large coagula, which relieved the oedematous condition of the neck. Several short and hesitating pains succeeded, as if the womb, startled by some unusual occurrence, had paused to reconnoitre; then came a prolonged, expulsive effort, and the child's head passed fairly through the os, distending the perinæum.

The termination of the labor was easily accomplished, and in less than half an hour a full-term male child was delivered. Unfortunately it had cyanosis, and in consequence survived only twenty-four hours. The mother experienced no untoward symptoms, either from the tediousness of the labor or the means employed for her relief, and is now (March 31st) convalescent. Duration of her labor, 102 hours.

In a few minutes after the birth of the child, the uterus, aided by very moderate pressure over the fundus, contracted firmly, expelling the placenta. The binder having been applied, a vaginal examination was made, to ascertain the condition of the cervix. A shallow notch marked the place where the incision had been made. There was no subsequent hæmorrhage, the lochia being even less profuse than usual.

With reference to the foregoing operation, Dr. Murphy, in his Lectures on the Principles and Practice of Midwifery (Second Edition), pages 246 and 247, observes: "If these means fail, it becomes a question whether we should wait for the death of the child, in order to remove it by the

crotchet, or incise the unyielding cervix. The former practice involves a sacrifice of life, but generally secures the mother from the injurious effects which may follow. The latter may be the means of preserving the child; but if the incision lead to a laceration of the uterus, the mother is at once placed in imminent danger of her life. The fear of such a consequence, it appears to us, has prevented any attempt from being made thus to cut through this Gordian knot of difficult labor in its first stage; but whether this, like other operations, is only surrounded by chimeras of the imagination, which some bold spirit will dissipate, remains yet to be proved. Incision has been performed without accident: the same may happen again, and we confess, in a case such as we have described to you, we should be more disposed to adopt the shorter course, in the hope of saving the child, than to wait until its death enabled us to remove it. *This, however, is but an individual opinion, and needs support.*"

He adds the following in a foot-note:—"Since these observations were first written (1845), several cases have been recorded in which the cervix has been incised, the child saved, and no mother lost. *Vide* Mr. Tweddle's case (*Guy's Hospital Reports*, vol. iv. p. 119); Mr. Butler's (*Medical Gazette*, vol. xx. p. 589); Dr. Buckminster's (*American Quarterly Journal*, October, 1847); Dr. Pagan's (*Edinburgh Monthly Journal*, August, 1854, p. 172)."

He refrains, however, from commenting upon these cases, expressing no opinion whether in his judgment incision of the cervix uteri should be included in the category of legitimate operations.

"Multiple incisions upon the neck" are recommended by Cazeaux, who asserts that "they render consecutive laceration far less probable than would a single incision." He adds:—"Very rarely will it be necessary to make them more than half an inch long, while they may be often less than this; for it is the almost universal practice to be content with cuts of from three to four sixteenths of an inch in depth only, around the circumference of the orifice. The lateral parts of the neck should be chosen for the incision, though, if necessary, they may be made upon the anterior lip, and, lastly, upon the posterior lip."

While not presuming to place our humble opinion in opposition to that of the distinguished obstetricians just quoted, we must confess that we are at loss to perceive the advantage of "multiple incisions" when one will prove equally safe and effi-

cient. It seems to us that, when practicable, a single incision should be made sufficiently free to ensure the easy escape of the head. If this be done, it is difficult to conceive why a consecutive laceration should occur. Indeed, both experience and reflection have convinced us that, when the incision is properly made, the danger of such an accident must be very small, if not purely hypothetical.

On the other hand, if the incision be not carried deep enough to accomplish *per se* the desired object, viz., the liberation of the head, it is difficult to understand why laceration should not take place, especially if the subsequent pains be violent and prolonged, as they naturally would be, excepting in cases of exhaustion, either general or of the uterus alone.

If the uterus were contracting vigorously, a laceration of greater or less extent would be very likely to ensue, when the obstacle to the advance of the head had been only partially removed by a timid and inefficient use of the knife. It is easy to comprehend how a slight cut or nick in the cervix might weaken its power of resistance at that spot, and thus become the point of departure of a dangerous, if not fatal laceration. This is certain—the depth to which an incision is carried is wholly within the operator's control; the extent to which laceration may take place lies wholly beyond it.

It seems to us, therefore, that if the knife is to be used at all, it should be used *freely*, so that when the uterus again contracts forcibly it may meet with little or no resistance from its own tissues to the descent of the fetal head. Should it appear that a sufficiently free incision could not be made through one lip only without endangering the integrity of the intra-uterine or of the abdominal structures, we are aware of no anatomical nor surgical reason forbidding the division of both the anterior and posterior lips, either at corresponding points of their respective segments, or at whatever point in each the greatest impediment seems to exist.

Such is the method, founded, as it appears to us, on rational and obvious principles, which we would submit for the guidance of the practitioner, or commend, at least, to his attentive consideration whenever it is proposed, in the language of Dr. Murphy, "to cut through this Gordian knot of difficult labor."

In the case we have detailed, we are persuaded that had we waited for "the death of the child in order to remove it by the

erchet," the mother would probably have perished also. Nearly equal danger to both would have attended the use of the forceps; and, had these failed, there would have remained no alternative but craniotomy, performed under circumstances highly unfavorable to the mother.

It remains to notice the possibility of dangerous hæmorrhage occurring as a consequence of the free incisions we have recommended, let it be understood, in exceptional cases only. We can conceive that such an accident might result, 1st, as a very rare coincidence, from the patient's possessing the hæmorrhagic diathesis or idiosyncrasy. 2d. Inertia uteri, spontaneous, or following anaesthesia from ether or chloroform, might give rise to flooding dangerous in itself, and rendered more so by the additional loss of blood to which incisions under these circumstances might give rise. As a precaution, therefore, just before the operation is performed a full dose of ergot might with propriety be administered, unless the patient were a primipara, or the medicine otherwise contra-indicated. And even in a first labor, should the uterine contractions have become feeble and infrequent, or have ceased altogether, and an evident necessity existed for stimulating the womb, ergot in small and tentative doses might be resorted to. It should be borne in mind, however, that ergot in such a case would be inadmissible unless it were evident that delivery could be effected before there had been time for its absorption. An attentive examination of the perinæum and external parts will enable the experienced practitioner to determine with sufficient accuracy the probable duration of this stage of the labor. If ergot is contra-indicated, opium, given in small and repeated doses, will prove a uterine motor-stimulant, to the good effects of which we can testify from long experience. Small as the danger probably is of any considerable hæmorrhage arising from incision of the cervix, our own judgment would be decidedly against the performance of this operation unless the uterus were contracting regularly and with power sufficient effectually to close the divided vessels.

NEW EDITORS OF THE ST. LOUIS MEDICAL REPORTER.—DRS. W. M. McPHEETERS and G. M. B. MANGHIS succeed Dr. O. F. POTTER in the editorial management of the *St. Louis Medical Reporter*. In future this Journal will be published monthly, instead of twice a month, as in the past.—*N. Y. Med. Rec.*

## SPONTANEOUS CURE OF TUMOR DURING PREGNANCY.

By DAVID RICE, M.D., Leverett, Mass.

ABOUT one year ago, I was consulted in regard to a tumor, situated on the base of the lower jaw, by Mrs. J. H., of Shutesbury. Mrs. H. is a married lady, aged about 24, of a good constitution, and generally healthy. I was called not only to examine the tumor, but for the purpose of removing it with the knife. Mrs. H. had shown it to several other surgeons, who advised her to have it removed at once. The tumor was about the size of a hen's egg, very hard, but slightly movable, and evidently not attached to the bone. It gave her some trouble, causing pain by pressure on the surrounding parts. In removing it, it would be necessary to ligate the inferior maxillary artery, and the operation for that reason would be quite a nice one. She had up to this time tried no local applications, and I advised her to wait and try the effect of such applications.

I gave her the tinct. of iodine, and directed her to apply it thrice daily. She tried the application as directed, but received, as she says, no benefit. I did not see the lady again until a few days ago. She called at my office to have a couple of teeth extracted. She brought along with her an infant, about two months old. Imagine my surprise on beholding that the tumor had disappeared. I found, on questioning her, that about four months after she became pregnant, the tumor began to disappear, and in a few weeks, eight or ten, she said it had entirely vanished! Nothing had been done in the meantime, by local or general means, to effect a cure. It was entirely spontaneous.

Here is a nut for physiologists to crack. Did the pregnancy, by counter growth, invite the vital forces so powerfully in behalf of the young being, as to produce the absorption of the tumor? Was it removed by the agency of counter irritation? Or did the pregnancy evolve some new principle in the blood, in itself curative. Did it disappear for want of nutrition, the fœtus requiring what the tumor needed for support? Will the child be more apt to inherit the growth hereafter? Will it be likely to reappear again in the mother? Have physicians often observed such cases in their experience? I would be glad to learn the views of medical gentlemen on this interesting case.

April, 1869.

## THE PATHOLOGICAL ANATOMY OF SURGICAL STUMPS.

By DR. CHAUVEL (Army Medical Staff).

Translated for the Journal from the Archives Gênérales de Médecine for March, 1864, by B. E. COTTAGE, M.D., of Roxbury.

(Concluded from page 238.)

WE may now ask what is the mode of formation of these protuberances, and what causes tend to their development. M. Hutin gives the following explanation:—"the nascent tubercle is either formed by the crowding back of the nerve-substance into the neurilemma as the latter is drawn upon by the cicatrix, to be afterwards augmented in volume by the addition of adipose matter; or else it is due to increased thickness of the cicatricial tissue, which continues to expand between the several nerve-threads within the common neurilemma."

This explanation appears to us very reasonable and perfectly admissible. We believe, however, that he is describing a mere phenomenon of inflammatory irritation, especially when we take into account the considerable development of fibrous tissue in the extremity of a stump. Divided muscles, vessels and nerves undergo a certain degree of inflammatory irritation during cicatrization, and this irritation induces hypergenesis of the connective tissue. There is not, nor can there be, a direct union between the extremity of a divided nerve and the adjacent tissues; but perhaps the development of a neuroma may be proportionate to the latent irritation which always remains, for a longer or a shorter time, in the extremity of an amputated member. We would like to study this cicatrization of nerves at successive periods, to ascertain at what time the protuberances arise, and at what moment they cease to grow, but as yet we have met with stumps of long standing only. Hypergenesis of the connective nerve-tissue, of the neurilemma, and of the perineuron, is, in our opinion, the primary cause of the formation of these neuromata. The nerve-tubes are thus distributed in bundles through the new tumor, and remain there without alteration.

Cruveilhier asks if friction and pressure, to which the extremities of the nerves in a stump are almost inevitably exposed, are not the active cause in the development of traumatic neuromata.

Analyzing in this point of view our eleven amputations of the thigh, we see that of seven who used the stuffed long peg, six presented very large neuromata of the sciatic. Of the four who used crutches, two only had medium-sized neuromata, and two

almost nothing. It would appear from these facts that when the stump was wholly free, there was much less tendency to the production of neuromata. Although the peg, in fact, ought not to take its bearing at the stump if properly stuffed, still there is an evident necessity, in order to make walking easy or even possible, that the periphery of the thigh should be in contact with the apparatus. Hence a certain dragging and a pressure which tend to force back the soft parts towards the axis of the member. If, on the contrary, a badly made apparatus allows a displacement of the stump at each movement, the chafed parts soon become painful, and walking impossible. All these inconveniences of the peg are increased necessarily when the remaining portion of the limb is very short, for which reasons two of the three whose thighs were amputated at the upper third, used crutches exclusively. But why in amputations of the leg, when the patient used a peg (pilon) which left the stump entirely free; in disarticulations of the shoulder, where the stump was not enclosed in any apparatus, for our patients seldom used any in these cases; why were these neuromata, then, as one may truly say, constant and almost always very large?

Even if the extremities of the nerves were found englobed in common fibrous tissue merely, still some authors would insist upon the influence of pressure. But even in this our facts appear contrary to such hypothesis. The neuromata were most commonly wholly free, in the midst of other parts, and buried in very loose large-celled cellulofatty tissue. We must therefore seek another cause, and one whose action may be as constant as the effect attributed to it.

May we see in the formation of such tumors a provision of nature for the protection of the ends of the divided nerves? To justify such an hypothesis the nerve should be enveloped in this fibrous shell entire, and not separated into bundles diverging into connective tissue. And further, such a fibrous crust would rather produce the opposite effect, for the extremity of a nerve free in the midst of soft parts, would escape with greater certainty the action of foreign bodies than a large, hard, and elastic tumor, offering a greater resisting surface.

We conclude, then, that the development of neuromata is due to inflammatory irritation which follows the operation and accompanies cicatrization, but that subsequent pressure and friction are not without influence on their enlargement. It is to this latent and prolonged irritation that we must

attribute the hypergenesis of connective tissue which constitutes neurilemma. The nerve-fibres undergo no alteration.

*State of the Bones.*—The opinions of Larrey, Hutin, and Legouest, were cited above, in our History of the subject. We proceed with our own conclusions.

The primitive phenomena which follow a section of a healthy bone are those of slight osteitis, with increased vascularity; the formation of fleshy projections; and more often an exfoliation of superficial layers from the surface of the section. Then the fleshy projections develop, run together, and, becoming calcareous, form osseous beds which close up the medullary canal opened by the operation.

Often at an autopsy of a stump the bone no longer exhibits a natural condition. But a distinction must be made between amputations in contiguity and those in continuity. In the first instance the bone, not submitted to traumatic lesion, takes on only that degree of inflammation which is necessary to remove its articular cartilage, and to contract adhesions to the neighboring parts. It is this indispensable elimination of cartilage, sometimes a very slow process, that greatly retards cicatrization in these operations. The subcartilaginous parts of the head of the bone alone inflame, and the epiphysitic periosteum remains sound, if all proceeds as desired. This process being finished, the head of the bone becomes atrophied with the soft parts, sometimes to such a degree that it is said that the femur has been known to terminate in a point, after disarticulation at the knee, and thus to render the use of ordinary artificial apparatus very difficult.

As to disarticulations, we have had chiefly stumps at the shoulders to examine, and all of long standing. In all four, the stumps were well nourished, and the shoulders were not sensibly atrophied. In three the shoulder-blade was natural. In one alone the glenoid neck was sensibly flattened, and slightly reduced in size. The only constant modifications were of the glenoid cavity. We always found it deprived of its articular cartilage, flat, or slightly convex instead of concave, and covered with a fibrous tissue not adherent to the cicatrix. The glenoid fibro-cartilage had disappeared, or become confounded with the fibrous tissue. The latter was only slightly adherent to the bone. The glenoidal surface was smooth, flat, and without marks of inflammation.

In these cases, it is true, the stump was not submitted to any influence powerful

enough to effect great modifications in the bones. A simple cover of leather served to protect the shoulder from direct blows, and no other artificial appliance was made use of. The soft parts abundantly covered the underlying bones, and produced no pressure upon them.

When the bones are required to furnish a point of support to a member the modifications are more grave. In partial amputations of the foot, cicatrices often ulcerate, and the subjacent bones inflame, and become carious, or necrosed. In an autopsy of an ante-scaploid disarticulation we found ulcerations of the soft parts, caries of the bones, and vegetations surrounding the altered surfaces. There was at the same time a partial luxation of the foot upon the leg; the astragalus was carried far in front, its posterior portion only being in contact with the tibio-fibular articulation. Walking had become impossible on these parts, and the patient used the short peg (pilon). The muscles of the leg were wholly adipose; and the tendons themselves had lost their pearl white appearance, had become fatty in their turn, and were easily broken.

In amputations in contiguity the bony extremities are more apt to inflame and to change in form and size from ossific productions or new ossiform formations—the result always of a certain degree of inflammatory irritation.

The following were the results in this respect in our series of observations: In eleven amputations of the thigh, the extremity of the bone was in seven instances considerably tumefied; twice it was not very sensibly modified; and twice no change could be discovered.

According to the place of amputation we found—of three at superior third, all considerably enlarged; of four at middle third, two considerably, one slightly, and one of natural size; of four at inferior third, two considerably, one slightly, with bony crests, and one of natural size.

Thus hypertrophy of the bony extremity by the addition of new layers, or the production of crests and ossific concretions, is to be found very frequently in amputations of the thigh, especially at its upper third.

As to the leg, we always found that the tibia had undergone very slight or quite inappreciable changes in form and volume. The fibula was uniformly dwindled, more or less pointed, and drawn towards the tibia.

In the arm the results were about the same. The humeral extremity was not sensibly modified. Now and then there were ossific crests, or slender projections on its edges;

quite as often it was slightly shrunken and its walls compressed together.

From our rapid sketch it would appear reasonable to adopt the conclusions of Larrey; that when the bone does not serve as a point of support, or sustains no pressure, as in stumps of legs, arms, &c., it gradually tends to become atrophied; while on the other hand, under opposite conditions, as in stumps of the thigh, its extremity becomes enlarged and club-like.

But we can admit only a part of the first proposition of Larrey. Instead of asserting with that illustrious surgeon that the end of the bone shrinks, flattens, and atrophies, our observations simply warrant us in saying that it usually preserves its natural volume, or only becomes slightly atrophied, or at times thinly covered with crests or bony accretions.

As to Larrey's second proposition—we remark that of two who suffer amputation of the thigh, one of whom walks with the long peg, the other with crutches, the first only ought to have a club-shaped bone, for he alone has the point of support at the extremity of the stump. But in our eleven amputations of the thigh, three used crutches exclusively, and yet these three presented large tumefactions of the femur. Of the eight which remain, four only showed such enlargements, and all these used the peg; that is to say, were most exposed to frictions, dragging and pressure.

It seems, then, difficult to attribute these osseous deposits to the mechanical influences invoked; and yet, when one sees that these productions form almost exclusively on the thigh, and never, or very rarely, on other parts, he finds it difficult to believe that irritation or latent inflammation is the principal cause, since this should act on all kinds of stumps alike.

There is, however, a special reason for this irritation in amputations of the thigh. Stumps of thighs, as we have said, have the greatest tendency to concavity. In spite of all precautions, the consecutive retractions of the soft parts are continually forcing forwards the thigh bone. This bone, in this way becoming thinly covered and badly protected against exterior influences, is now more subject to pressure and friction. Thus a continued source of latent inflammatory irritation, whence the production of new osseous layers is readily comprehended.

These ossific concretions take on all possible appearances, and give to the ends of the bone shapes as different as those of the stumps themselves. Sometimes there are only slight projections or crests of a few

lines in height; sometimes, again, for a considerable extent there are very regular layers, which double or triple the thickness of the bony walls. In some this transformation does not exceed a third or half an inch; in others the hypertrophy rises three to five inches above the surface of the section, and gives the bone the almost exact form of a pestle.

When the medullary canal closes, it is almost invariably effected by a layer of new bone. We are wholly ignorant at what precise moment this takes place. We can only say that in three of the eleven amputations of the thigh we found this obliteration incomplete; an exception still more rare in the tibia and fibula. The firm, rounded passage which led into the medullary canal, varied in diameter from one to three-tenths of an inch, or thereabouts. Surrounded by a very thin and fragile bony rim corresponding to the centre of the osseous section, this passage was closed up by a dense, almost cartilaginous tissue. The operations dating back twelve or thirteen years, there seemed little probability that the obliteration was of recent occurrence.

When the medullary canal is closed, as it usually is, the thickness of the bony layer closing it varies from less than a twentieth to more than half an inch. This layer is often so thin as to be quite transparent, but always so dense, hard and resisting that it cannot be pierced by the scalpel.

All these osseous layers of new formation were, in fact, composed of compact tissue, hard as ebony. Ordinarily no decided line of demarcation existed between the old bone and the new accretion. Perhaps, nevertheless, the new tissue may have had a little deeper color, while tending to a characteristic greyish tint, especially in the central portion of the growth.

Unfortunately, we did not examine this new tissue with the microscope, to determine whether it was formed of true bone or of mere calcareous deposits; but its mode of formation, its aspect, and its structure, all led us to the former hypothesis.

The surrounding fibrous tissue gave to these osseous productions a periosteal covering which adhered intimately. Vessels traversed it and passed into the bone. It is the internal layers of this fibrous tissue that become ossified by the latent irritation, which follows operations and is induced by shocks and friction.

In members of two bones (leg, fore-arm), the bones, being no longer retained apart, tend, after section, towards each other at their extremities. On them osseous vege-

tations were less abundant and less developed. We have seen the shrunken fibula inclining towards the tibia, and united to it by strong fibrous bands; and even, in one case, by a true, compact, and very resisting, osseous bridge.

Such were the principal transformations we met with in Surgical Stumps. We regret that we had not a larger field and more varied observations to render a study of the subject at once more complete and more interesting.

### THREE REMARKABLE CASES OF ARREST OF DEVELOPMENT OF THE EYE, OCCURRING IN THE SAME FAMILY.

In a family residing in one of our neighboring towns, three very remarkable cases of arrest of development of the eye have occurred. Besides the father and mother, the family consists of nine children. The youngest, a baby of a week old, was born with the left eye only about half developed—presenting the appearance that is often found in an eye which has been destroyed through the agency of a large ulcer of the cornea. It is about half the usual size, with a central opacity, the cornea being partly formed, and the iris can be distinguished, though smaller than normal. No pupil can be discovered. The other eye is perfectly formed. The second case is a boy of seven years of age, whose right eye is only partially formed, presenting a similar appearance to the first. In the last case, a boy of 14, the right eye has wholly disappeared, there being nothing in the socket but the conjunctiva, which lines the cavity. The left eye presents nothing abnormal. The children are all healthy and robust. Nothing of a similar nature has been known to exist in any of the ancestors. The father and mother have perfectly formed eyes.

Thinking these cases might be interesting to the readers of the JOURNAL, and having never seen similar ones spoken of in works on the eye, I thought them worth reporting.

CERTIFICATES of attendance on the several courses of lectures delivered in the College of Physicians and Surgeons, New York, will hereafter be recognized by the Royal College of Surgeons of England, and the Diploma of Doctor in Medicine of the said College will also be recognized.—*N. York Medical Record.*

## Hospital Reports.

### BOSTON CITY HOSPITAL.

Reported by FRANK W. DRAPER, M.D., House Surgeon.

*Lithotomy.* (Service of Dr. CHEEVER.)—The patient, a very debilitated man, of restless and fretful disposition, and 68 years of age, entered the Hospital in November, 1868, having suffered from the symptoms of stone in the bladder during the whole of the previous year. He had complained of pain in the bladder and urethra, and was made especially uncomfortable by the continual incontinence of urine. At the time of entrance the urine passed guttatum, and with much pain. It had been found necessary to resort to opium on account of the distress. He was much reduced in strength, and the general constitutional disturbance was marked.

The sound detected the presence of a calculus of large size. Under ether, bilateral lithotomy (Düpytren's operation) was performed, both incisions being semi-circular with the concavity opening downwards. On opening the bladder through the prostate, two stones were discovered, a small one and one much larger. The former was removed without much difficulty, but for the delivery of the latter it was found necessary to enlarge the opening. This larger calculus was irregularly spheroidal, its long circumference being *seven inches*, and its shorter *five inches*. It weighed 1320 grains; equal to  $2\frac{3}{4}$  ounces. An elastic catheter was fastened in the bladder through the wound.

Stimulation was found necessary near the close of the operation, but in six hours the patient reacted perfectly. During the three days succeeding the operation he was comfortable and in satisfactory condition. Nourishment was taken quite freely, and the constitutional disturbance was comparatively slight. On the fourth day, however, typhoidal symptoms began to develop themselves. The pulse went from 90 to 104–108. The appetite was lost, the tongue dry and brown, and a diarrhoea set in which for a time resisted remedies. Meantime, the catheter was removed and the urine passed freely through the opening in the perinæum. The wound was indolent and sloughy at the edges.

After three days of this relapse, the symptoms began gradually to improve. All the unfavorable signs gave place to an encourag-

ing condition of things. The wound improved daily, and healthy granulations succeeded the indolent and sloughy condition previously existing. With increasing improvement, the petulance and dissatisfaction of the patient increased, and on the seven-teenth day after the operation, at his urgent request, he was discharged, with the cure progressing favorably. Three months later he reported himself as quite well.

*Fatal Case of Wood's Operation for the Radical Cure of Hernia.* (Service of Dr. CHEEVER.)—D. K., aged 50 years, had had double oblique inguinal hernia ten years, brought on by violence. An attempt had been made about five years previously to his entrance to Hospital to cure the affection, by some subcutaneous operation, but with only partial success on one side. He found that in his occupation the truss he wore was an insufficient safeguard, and he desired some radical operation. With a view to preparing himself better for the operation, he had unwisely "dieted," and had abstained from meat during the week previous to his entrance, although he did not report the fact at the outset.

Under ether, Wood's operation, with the wire sutures, was performed; on one side a double cross stitch was taken in the spermatic fascia, and on the other side a single one. The inguinal rings were large, and the pillars were easily approximated and the openings closed. The subsequent constitutional disturbance was primarily considerable. Moderate pain was controlled by morphia. On the day following the operation, the patient reported himself comfortable. The wound was quiet, and its edges were without irritation. There was no pain in the abdomen, and no symptoms of general disturbance. But the patient could not be induced to take food, and resisted all advances in that direction.

During the second night after the operation the scrotum and penis became extremely œdematous and red and tender; and the edges of the wound in the scrotum had commenced to slough. The patient had passed a restless night; his pulse, before 96, now became 104. There was still complete anorexia, and the general constitutional disturbance was marked. The conjunctivæ assumed a straw color. There was a tendency to mild delirium. The abdomen was slightly tympanitic and tender.

Under ether free incisions at each side of the scrotum and down the dorsum of the penis set free the serum, and discovered the sloughing process to be already fully established. A dressing of diluted solution of

chlorinated soda was applied. The wires were removed and all the parts left free. Quinia and aromatic sulphuric acid were exhibited, alternating with brandy and beef-tea. Partial relief followed these active measures, but the tendency was unfavorable. Food and stimulants were still taken with difficulty and under protest. The abdominal symptoms became more grave. Pulse 108, weak. Mind generally clear.

On the fourth day all the symptoms were increasingly unfavorable. The patient did not complain of much pain, but the general depression was excessive, and stimulation failed of producing any effect. The abdomen became markedly tympanitic. The scrotum and penis continued to undergo decomposition. In spite of remedies, the patient sank and died ninety hours after the operation.

*Croup; Tracheotomy; Recovery.* (Service of Dr. CHEEVER.)—Edward L. G., aged 2½ years, entered the Hospital Nov. 17th, with the following history. He had been attacked with symptoms of croup twenty hours previously; free administration of ipecac. had brought no relief, and his removal to the Hospital, with a view to tracheotomy, was advised. At entrance, the respiration was very hurried and gasping; the face was livid, and symptoms of great gravity were obvious. Pulse 140, jerking and feeble.

Tracheotomy was performed under ether, the operation being without complication, and attended with immediate relief to all the distressing symptoms. The patient was removed to steam-room, the temperature of the room being maintained at 75°.

After two hours the child took milk, and was breathing quietly, occasionally throwing bloody sputa from the tube. The pulse fell to 120. The following mixture was given, in drachm doses, every four hours:—

R. Tr. ferri chloridi, ʒi;  
Tr. opii camph., ʒij;  
Syr. aurantii, ʒiiss. M.

The first night was passed in comfort. The respiration was generally quiet, and was disturbed only by paroxysms of coughing, in which fragments of false membrane were ejected. The inner tube was removed and cleaned every two hours. The appetite of the patient improved hourly, and milk and beef-tea were administered freely. During the three days following the operation, a diarrhea was present as a complication; it subsided under opiates.

On the fourth day the tube was removed, but as distressing paroxysms of coughing

supervened, it was replaced, under ether. Improvement was steady until it was again removed, on the eighth day after the operation. The cough had in great measure subsided, and there was no evidence of an extension of the formation of the membrane in the air passages.

The wound healed kindly, and with satisfactory rapidity. The general condition improved proportionately, and the patient was discharged, well, on the fifteenth day after tracheotomy.

NOTES FROM THE GAZETTE HEBDOMADAIRE  
DE MEDECINE ET DE CHIRURGIE.

*M. Claude Bernard on Opium and its Alkaloids.*—The effect of extract of opium as compared with that of morphine, is thus illustrated by M. Claude Bernard. A pigeon got ten centigrammes of extract of opium under its skin, and another pigeon had inserted into it in the same manner ten centigrammes of chlorhydrate of morphine. At the end of five minutes, the first pigeon was seized with slight convulsive movements, which soon increased, and became so intense that the bird rapidly died in convulsions. The pigeon which got the same quantity of morphine as the other had of extract of opium, remained, on the contrary, absolutely unharmed. Retained before the eyes of the audience during an entire lecture without showing the slightest trace of *malaise*, he survived the experiment as though nothing had been done to him. Subsequently, M. B. stated that pigeons are very refractory to stupefying agents. Bernard infers that there are two eminently different agencies in opium. In fact, out of the six alkaloids of opium, three are soporific and three are convulsive. The first three, stated in the order of intensity of soporific action, are narceine, morphine and codeine; the second class, ranged in the order of intensity of convulsive action, are thebaine, papaverine and narcotine. Again, the three hypnotic alkaloids, notwithstanding their mutual analogy, pre-

sent real differences *inter se*. Thus, narceine causes profound sleep, but as soon as that sleep is awakened from, the faculties are quickly recovered. It is not so with morphine. M. Bernard relates this fact. Into one of two dogs accustomed to play together he injected five centigrammes of morphine; into the other, the same quantity of narceine. They both went to sleep. But, on awaking, the animal which had been poisoned by morphine was morose and flurried, not recognizing his companion; while the other immediately resumed his playfulness. The following day the experimenter reversed the conditions, causing the animals to interchange their rôles; and the result obtained confirmed by the counter experiment the first demonstration.

Clinical experience amply sustains the following inference drawn by Bernard. The hypnotic alkaloids of opium have two successive periods of action—the first, that of excitement; the second, that of stupor.

Our author now makes a further classification of the alkaloids of opium, dividing them into three classes, in the order of their intensity of action, as follows:—

<i>Exciting.</i>	<i>Soporific.</i>	<i>Convulsive.</i>
1. Codeine.	1. Narceine.	1. Thebaine.
2. Morphine.	2. Morphine.	2. Narceine.
3. Narceine.	3. Codeine.	3. Papaverine.*

Bernard claims to have demonstrated that the common opinion is correct, that the immediate action of narcotics is upon the brain.

We subjoin the following statement from the *London Medical Times and Gazette*:—

"Most of our readers are aware that Dr. Weir Mitchell, the American physiologist, announced some months ago that pigeons appear to be insusceptible of the action of opium. He administered twenty grains to a pigeon in one day without the slightest effect resulting. At the meeting of the Medical Society of London on April 5th, Dr. Richardson exhibited a pigeon on which a similar experiment had been tried, but had been carried to much greater length. This bird, which appeared to be in perfect health, had been first treated by the subcutaneous injection of morphia, two grains being injected at once. Twenty-one grains of opium were then administered to it on

three successive days. The dose was then increased to thirty grains, which quantity was also taken daily for three days. Finally, for five days, the same pigeon took sixty grains of solid opium daily, and, at the end of the time, remained in apparently perfect health. After the injection of morphia, Dr. Richardson noticed that the pigeon vomited slightly; but he thinks this was rather due to the operation than to the physiological action of the alkaloid."

We presume M. Bernard has verified the convulsive action of extract of opium (subcutaneously injected) by repeated experiments; and the question therefore arises, was the opium which Dr. Richardson's birds "took" digested and absorbed? and if it were, why are they not convulsed? The subcutaneous injection of morphine, both by Bernard and Richardson, had the same result of impunity. Bernard also states, as above cited, that pigeons are very refractory to "stupefying" agents.

As to the *local* action of "anæsthetics,"\* the Professor is inclined to allow its real existence; and denies that it is at all contradictory to the theory of the exclusive action of narcotics on the brain. He invokes the theory of Bichat—which, though it has been often called in question, he is disposed to admit—that the nervous ganglia are rudimentary brains disseminated throughout the whole body. Each one of these ganglia presides over, or at least influences, within a circumscribed zone, the action of one or another organic system. Though the ganglion is in subordination to the direct influence of the encephalon, M. Bernard claims to have shown that it is to a certain extent possessed of "autonomic" action. He expresses the opinion that in the local application of narcotics their first action is on the ganglia, the brain playing but a secondary part. Thus, a narcotic applied to the intestine paralyzes first the ganglia of that intestine, and after that the encephalon may be brought under its influence. For the purpose of showing the local action of a narcotic on the functions of an organ he exhibited two pigeons; one of which had, the evening previous, received

\* Previously, Bernard is reported as placing papaverine 2d, and narcotine, 3d. There is, therefore a misprint somewhere.

\* It is evident from the context that Bernard means something quite different from the practical fact of the local and external insensibility produced by freezing, &c. —EDITOR.

ed into its stomach ten centigrammes of morphine. Its gizzard was full, although it had not taken food for twenty-four hours; while the gizzard of the other bird, which had taken no morphine, was empty, both pigeons having been fed at the same time and with the same quantity of food. Further experiments are requisite here, he acknowledges, because morphine subcutaneously injected produces the same effect, to the extent of notably impeding the digestion.

We ask, as we did in relation to opium ingested by pigeons, was the morphine digested and absorbed?

*Ophthalmic Hygiene of Type-setting.*—Dr. H. Kohn has been examining the eyes of 132 compositors in printing offices. Half of the subjects were near-sighted. That is, of the 132, there were 68 near-sighted—51.5 per 100. 7.6 per 100 were hyperopic. Comparing these results with those observed among scholars and students, there were found among the former 55.8 per 100, and among the latter 60 per 100, myopic. Among the 68 myopic typographers, 51 had begun life in the enjoyment of good eyesight.

The employment of artificial light had a marked influence. The proportion of the near-sighted compositors who used oil lamps was greater than that of those who worked by gas. Further, out of 125 typographers, those who of their own choice used gas numbered 75; those who preferred oil, 42; and those who selected petroleum, 9. The temperature developed in the vicinity of the eyes was for oil, 22°5; for petroleum, 22°; for gas, 21° [Centigrade].

In fine, the predominant affection of the eyes among compositors is progressive near-sightedness. M. Kohn advises them to secure a good light by day; and at night to use a lamp [or burner] with a chimney and a shade, so arranged as to illuminate only the objects on which they are at work—not, the eyes of the compositors. He counsels them to dispense with small type; and to confine themselves to a comparatively short amount of daily labor—particularly not to work from eight in the morning till ten at night, with one hour only for

meals; for such is the custom in most of the printing offices of Breslau.

No appeal is made by M. Kohn to the humanity of writers for the press to furnish legible manuscript.

At a meeting of the *Société Médicale des Hôpitaux*, M. Raynaud read a note upon a new parasitic affection of the lingual nervous membrane. The affection is entirely local, and is not a serious one. M. Raynaud has met with it twice, and has found it characterized by an alteration of the epithelium of the lingual papillae, and by the presence of a vegetable parasite consisting entirely of spores. The spores resemble those of the *Tricophyton* of *Herpes circinatus*, &c.

A NEW METHOD FOR SECURING DIVIDED VESSELS is described by Dr. LENTE, of Cold Spring, N. Y., in the *American Journal of the Medical Sciences*.

"The idea is simply this: cut off a length of silver wire, say three inches, less will do, however, for small arteries; give it a sharp bend in the middle, then one or two twists as near the bend as possible. This forms the ligature. *Mode of Application.*—Secure the twisted end of the ligature in a pair of spring or catch forceps, and it is ready. Draw out the vessel to be ligated, or, if a small one, the tissue in which it is, with a tenaculum or forceps, in the usual manner; let an assistant apply the ligature against the vessel at the point where the two legs diverge from the twist; then the surgeon takes hold of the two ends and gives as sharp a twist on the vessel as possible, and then secures the hold by two or three half turns. The silver wire is so soft and pliable that but very few turns are necessary to prevent slipping. After a little practice, these ligatures may be applied with great facility. At first, it is a little awkward compared with the silk ligature, but compared with any other mode of securing vessels it is more simple. As regards the size of the wire, the surgeon will perhaps use his own judgment; but I have used ordinary suture wire for the smaller arteries, and a larger wire, No. 26, for large arteries. The suture wire would be strong enough to hold any artery, I think; but if drawn tightly it would probably be more liable to damage the inner coats, which is not desirable, and there is more uncertainty in making the twist take a firm hold of the artery while tightening the larger wire.

The surgeon, having twisted the wire, cuts off the end with ordinary scissors, within two or three turns of the artery; the other end, if not too long, may be left, as we thus avoid having *two* sharp ends to the ligature. This leaves a very minute quantity of metal around each vessel, so little, in fact, that after a dozen such ligatures have been applied, it becomes somewhat difficult, in course of half an hour, to find one of them, except by searching carefully. They soon imbed themselves in the tissues, and disappear from sight.

"The advantages of this mode of ligating are obvious, provided we can be secure against further trouble from the foreign substances left in the wound. I was induced to believe that pure silver would become encysted, and would thus not give rise to any future inconvenience from the fact that substances, much more likely to irritate and inflame the tissues, remain in them harmless for an indefinite time."

In an elaborate article entitled "Experimental Researches on the Physiology of the Cerebellum," Dr. S. Weir Mitchell describes his experiments on that organ, and compares them with those of other observers. He says:—

"I have caused irritation of the cerebellum in pigeons, rabbits, and guinea-pigs, by the following processes: by inserting a strong needle-like awl through the skull; by injuring the organ after trephining, or, in birds, after slicing off a piece of skull; by injecting into the cerebellum globules of mercury with or without a minute amount of persalts of iron to arrest hæmorrhage; by freezing the part more or less, and allowing it to thaw so as to cause congestion; and lastly, by painting the exposed part with tincture of cantharides or other irritant fluid. . . .

"In the light of all that I have previously pointed out, I shall now review the question of cerebellar function.

"We must admit, in the first place, that apparent loss of co-ordination follows cerebellar lesions. It appears clear from my own researches, that these injuries do not cause this result, owing to mechanical and incidental affections of near parts.

"In birds, injuries and congestion of the spine give rise, at first, to seeming in-coordination, or at least to exactly such phenomena as follow like injuries addressed to the cerebellum. When the cerebellum has been removed spinal irritation still continues to evolve the same symptoms as when the

cerebellum exists untouched. These facts indicate for these two organs in birds, at least, a curious community of pathological symptoms, and probably of physiological function. If, then, there be such a functional entity having a separate seat as the so-called co-ordination, it belongs in birds to an extensive region, including the cerebellum and a large part of the spine.

"There is yet possible, however, another view of cerebellar activity which will accept all the facts and account for all. Let us suppose the cerebellum to be a great ganglionic mass, possessing the same motor functions as the gray matter of the spine, related like it, and through it, to the voluntary muscles. Irritations of its tissue, ablation, the temporary equivalent of extensive irritation, congestions, as from cold or other causes, might occasion both directly through the spine, or indirectly by reaction on its ganglia, just such confusion of motion, restlessness, and locomotor disorders, as we do actually see, and as were said entitle it to be called the organ for co-ordinating muscular acts. As the irritation disappeared, so would the muscular disturbances, until, when there was no longer irritation, there would cease to be locomotor difficulties of the character described, the spinal centres having by degrees assumed with the aid of the will the function shared in health with the lost organ.

"Referring anew to laws of research laid down at a former page, I remind the reader that if an organ be lost, and no function *finally* disappears, it either had none or possessed one in common with some part which remains uninjured and capable of at last supplementing the function of the destroyed tissues. For these reasons I am disposed to deny to the cerebellum any larger share in co-ordination than exists in any ganglion employed in voluntary motion, and to assign to it a part closely relating it in powers to the chain of spinal ganglia. The cerebellum becomes for me, therefore, a great reinforcing organ, capable of being more or less used in volitional muscular motion. Its loss, as I have elsewhere stated, leaves finally no functional defect save some incapacity for prolonged motor activity.

"The apparent in-coordination which follows section through the deeper layers of the cerebellum, is simply a confusion of movement due to the joint action of two separate and interfering agencies. In health the cerebellum is called upon by the will when needed, and acts through the spine

on the muscles. After irritation or ablation (the equivalent, for a time, of extensive irritation), we have two sets of forces in action—that arising from the excited and wounded efferent cerebellar fibres, a force inconstant, irregular, involuntary; and secondly, the normal activity of the will, which, in presence of the former disturbing power, fails to evolve the usual orderly reply from the muscles. The general result is seen in the strange confusion of movement which is so familiar to the physiologist. . . .

"I ought to add, that while I believe the cerebellum to be one of the great centres of force-development for voluntary, and perhaps involuntary motion, I am not at all prepared to assume that it has no other function.

DR. JOHN D. ATLEE describes a Laryngeal Tumor removed by opening the Larynx, after the insertion of a tube into the trachea.

"The patient was a boy of 15, previous to his disease hearty and robust. For 16 months he had been aphonic. Dyspnoea had become so urgent that asphyxia seemed impending. Attempts to use the laryngoscope had been unsuccessful from irritability of the fauces. On the 3d of October Dr. Atlee opened the trachea and inserted a tube. The presence of the tube was easily tolerated, and the patient exhausted by previous loss of blood fell, almost at once, into a deep sleep.

"November 17, I opened the larynx in the usual way, the patient being partially under the influence of an anæsthetic. On exposing the interior, masses of abnormal tissue presented themselves at the opening, during the efforts of coughing made to get rid of the blood flowing into the trachea. These were seized with the forceps from time to time and removed. Three portions, the first as large as a small filbert, the others the size of peas, were torn from their attachment to the mucous membrane. The ventricle of Morgagni on the left side seemed filled by this tissue. The whole amount removed would fill a large sized sewing thimble. As determined afterwards, it weighed twenty grains.

"After thoroughly cleaning the interior, a stick of nitrate of silver was rubbed thoroughly over the whole raw surface, and the external wound was closed by two harelip sutures and adhesive strips.

"The tumor removed, on examination, displayed under the microscope the anatomical elements found in epithelial growths.

"I saw this patient on the 21st of Janua-

ry. He had entirely recovered his voice, and was going to school. He had been kept from school a year and a half on account of the loss of voice. When first seen he was pale, emaciated, and rapidly losing flesh. He had become rosy, robust, and weighed 86 pounds in place of 64. He appeared in every way perfectly well."

CARBOLIC ACID AND HOSPITAL MORTALITY.—M.D., in *London Medical Times and Gazette*, says:—

"In answer to your correspondent who inquires as to the effect of carbolic acid on the statistics of Hospital mortality, I would beg to refer him to the annual reports of the Glasgow Royal Infirmary, the last of which, for 1868, has just been published. If he will take the trouble to calculate the mortality from the primary and secondary amputations of the thigh, leg, arm, and forearm before and after the introduction of carbolic acid into that Hospital, he will find that the results are not in favor of the so-called antiseptic plan of treatment. In the years 1860, 1861, and 1862—before the introduction of carbolic acid—I find 126 of the amputations I have mentioned recorded. Of these 126 there died 41, which gives a mortality of 1 in 3. On the other hand, in the years 1867 and 1868—or since carbolic acid has been used so extensively in that Hospital—there were 73 amputations of the same kind. Of these 30 died, giving a mortality of 1 in 2½.

The results are even more unsatisfactory if we take the compound fractures, which are the cases reported to be the most benefited by the carbolic acid treatment. I find in the three years already mentioned that there were 114 compound fractures treated in the Infirmary, of which 26 died, or nearly 1 in 4½. In 1868—a year in which, as I have been told, all the surgeons to the Hospital used carbolic acid—there were 59 compound fractures treated with a mortality of 20, or more than 1 in 3. Your correspondent may digest these data at his leisure.

NATIONAL CONVENTION FOR THE REVISION OF THE PHARMACOPOEIA OF THE UNITED STATES.—At a meeting of the Convention, held in May, 1860, the following resolutions were adopted:—

"1. The President of this Convention shall, on the first day of May, 1869, issue a notice, requesting the several incorporated State Medical Societies, the incorporated Medical Colleges, the incorporated Col-

leges of Physicians and Surgeons, and the incorporated Colleges of Pharmacy throughout the United States, to elect a number of delegates, not exceeding three, to attend a general convention, to be held at Washington on the first Wednesday in May, 1870.

"2. The several incorporated bodies, thus addressed, shall also be requested by the President to submit the Pharmacopœia to a careful revision, and to transmit the result of their labors, through their delegates, or through any other channel, to the next convention.

"3. The several medical and pharmaceutical bodies shall be further requested to transmit to the President of this convention the names and residences of their respective delegates, as soon as they shall have been appointed, a list of whom shall be published, under his authority, for the information of the medical public, in the newspapers and medical journals in the month of March, 1870."

In compliance with the above resolutions, the President of the convention announces that a meeting will be held in Washington, D. C., on the first Wednesday in May, 1870, and requests that the several incorporated bodies shall, after a revision of the U. S. Pharmacopœia, send the results of their labors to the convention, and further requests that they transmit to the President the names and residences of their several delegates, so soon as elected, that the list may be published.

Geo. B. Wood,  
President of the Convention of 1860.

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY.—At the annual meeting, at Waltham, April 14th, 1869, the following officers were chosen, viz.:—*President*, Jeffries Wyman, of Cambridge. *Vice President*, Howland Holmes, Lexington. *Sec'y*, C. E. Vanghan, Cambridge. *Treasurer*, John W. Willis, Waltham. *Censors*.—A. P. Hooker, H. H. Pillsbury, G. C. Lincoln, S. W. Driver, L. R. Stone. *Councillors*.—Anson Hooker, R. L. Hodgdon, W. W. Wellington, G. I. Townsend, Morrill Wyman, J. B. Taylor, A. Hosmer, J. W. Bemis, J. C. Dorr, J. T. G. Nichols, T. P. Robinson.

ASSOCIATION OF AMERICAN MEDICAL EDITORS. *New Orleans, May 6*.—A number of editors of American medical journals were in attendance at the meeting of the American Medical Association here, and formed an organization under the name of "The Association of American Medical Editors." Dr. N. S. Davis, of the *Chicago Medical*

*Examiner*, was chosen *President*; Dr. W. M. McPheters, of the *St. Louis Medical and Surgical Reporter*, *Vice President*; Dr. W. S. Mitchell, of the *New Orleans Journal of Medicine*, *Permanent Secretary*; Dr. J. B. Lindsey, of the *Nashville Journal of Medicine*, *Secretary*. The Association will hold its annual meeting at the same time and place as the meeting of the American Medical Association. The latter meets next year at Washington, D. C.

SPECIMENS OF OPIUM.—Report by Dr. Schrott, Prof. in Wien, on the Opium sent to the Paris Exposition Universelle of 1867.

Turkey, Egypt, India, Algiers—Merek, Howard and Macpharlan—sent specimens of opium. Della Sudda exhibited six specimens containing 10 per cent. of morphine; Adrian, a specimen from Smyrna, same strength.

From Egypt came three sorts, containing respectively 2-3, 5, and 8 per cent. Persian opium in various forms contained 8-10, 13, 9, 13; Smyrniote, three sorts, 5-11 and 12 per cent. Two sorts from Constantinople, 10-12-16. Adulterated Turkish, 1½-3. Indian, from Patna and Benares, 5-5½; Malvaopium, 5½; domestic, grown and manufactured in Darmstadt, 1848, 15 per cent., but in 1854, the crop from the same place yielded only 1½ per cent. Many sorts, especially the Persian in the form of sticks, seem to have gained considerably in strength; formerly this contained only 1 per cent., now 8-10. This is ascribed to the absence of starch, with which the older specimens were adulterated.—*Allg. Wiener Med. Ztg.* No. 12.

D. F. L.

EXAMINATION OF PORK.—Tiemann, Conservator of the Zoölogical Museum at Breslau, recommends the thorough examination of a single bit of muscle, taken from the diaphragm or psoas major of the slaughtered swine. He uses a lens that magnifies only ten diameters; saying that the trichina is much more likely to be overlooked when a higher power is used.—*Allg. Wiener Med. Ztg.*, No. 8.

D. F. L.

TO THE LONDON MEDICAL TIMES AND GAZETTE.—With reference to the "iron bar case," we would explain that the tamping iron entered by its pointed end, the left side of the face, immediately anterior to the angle of the lower jaw, and passing obliquely upwards, and obliquely backwards, emerged in the median line, at the back part of the frontal bone, near the coronal suture.

## Medical Miscellany.

**PERTUSSIS.**—Oppolzer says (*Höfner's Medicale Presse*) narcotics and astringents appear to reduce the duration of the disease about one half. Belladonna is probably the best, but simply because of its narcotic action. Tannin acts well in the third stage, or that of expectoration. In the case of children one or two years old, he began with pulv. rad. belladonna, gr. 1-12th, morning and night, gradually increasing up to gr. 1-8th, or gr. 1-6th, taking the pupil as a guide. Emetics are only given when the bronchial tubes are filled with masses of mucus. To those who were arrived at years of discretion, he also gave sodæ bicarb. 3ss., in a tumbler of sweetened water, a mouthful to be swallowed just before an anticipated paroxysm, for diluting the phlegm. The following also acts well the same part:—

R. Coccionella, gr. v-vijj.  
Potassæ carbonatis, gr. x.  
Aque f. dest., 1℥i. M.

Sig. Give a tablespoonful every two hours.

Change of air is good, even if patient can be removed but a few miles. If this is not procurable, keep the patient in a room with an equable temperature. For the resulting anemia use good diet. Dr. Link's extract of meat is good. Medicine may also be required.

In conclusion, it may be stated that of late many French physicians recommend the exhalations from lime which has been used in purifying burning gas, or, better still, gazéol. Oppolzer has had no experience with these remedies.—*Dublin Medical Press and Circular.*

ALL natural wines, if any improvement is to be effected by age, must throw down a deposit, and thereby they become sweeter in bottle by the elimination of their tannin, tartrates, &c. From red wine the deposit contains tannin, which, uniting with the albuminous matter contained in the wine, forms a crust, that year by year becomes less and less, until at length it becomes so thin that it acquires the name of "beeswing." The deposit also takes the form of crystals, which will both adhere to the cork and fall to the bottom of the bottle like powdered glass. All natural wines that have been any length of time in bottle should therefore be decanted with care.—*Ibid.*

In the last Annual Report of the Smallpox and Vaccination Hospital, London, occurs the following statement:—

"The opinion which, early in the course of the late epidemic, the officers expressed on vaccination, neither requires, they say, qualification, nor admits of limitation. They repeat:—Although it has not entirely fulfilled the sanguine anticipations of its earlier advocates, it is the greatest boon which was ever conferred by man upon his species. Properly performed, with good active lymph, and with not less than four punctures producing vesicles, and these running the course so minutely and graphically described by Jenner, and leaving not less than four typical cicatrices, vaccination robs the most fatal and acute disease known

in this country of its malignity, and reduces the mortality of smallpox from 35 per cent., or even a higher rate, to less than 1 per cent."—*London Medical Times and Gazette.*

**PROF. LEE** has described a new disease, or, as he termed it, an unpublished disease, namely, *Ammoniamia*. He commenced by saying, that it must be put alongside of uramia and of albuminuria, with which it had been confounded; its etymological meaning is, adulteration of the blood by carbonate of ammonia.—*Richmond and Louisville Medical Journal.*

**TORSION OF ARTERIES.**—Prof. Humphrey, of Cambridge, has published a lecture on this subject. He has for several months back abandoned the use of acupressure, of which method he was a follower, and has used torsion in all cases exclusively, meeting always with the best results, even in amputations of the thigh or leg.—*American Journal of Obstetrics.*

### MEDICAL DIARY OF THE WEEK.

MONDAY, 9, A.M., Massachusetts General Hospital, Med. Clinic. 9, A.M., City Hospital, Ophthalmic Clinic.

TUESDAY, 9, A.M., City Hospital, Medical Clinic, 10, A.M., Surgical Lecture. 9 to 11, A.M., Boston Dispensary. 9-11, A.M., Massachusetts Eye and Ear Infirmary.

WEDNESDAY, 10, A.M., Massachusetts General Hospital, Surgical Visit. 11 A.M., OPERATIONS.

THURSDAY, 9 A.M., Massachusetts General Hospital, Medical Clinic. 10, A.M., Surgical Lecture.

FRIDAY, 9, A.M., City Hospital, Ophthalmic Clinic; 10, A.M., Surgical Visit; 11, A.M., OPERATIONS. 9 to 11, A.M., Boston Dispensary.

SATURDAY, 10, A.M., Massachusetts General Hospital Surgical Visit; 11, A.M., OPERATIONS.

TO CORRESPONDENTS.—The following communications have been received:—Records of Middlesex South District Medical Society—Records of Boston Society for Medical Improvement—Nomenclature of Diseases—Cataract in Children—Accommodation of Eyes in Birds—Chloride of Gold in Microscopy.

PAMPHLETS RECEIVED.—Anatomie et Physiologie du Poinçon considéré comme Organ de Sécrétion. Par le Docteur Fort, Ancien Interne des Hôpitaux, Prof. d'Anat. et de Phys. à l'Ecole Pratique, &c., Paris.

MARRIED.—In South Dedham, May 1st, Francis M. Cragin, M.D., to Miss Mary E. B. Day.

DIED.—In this city, 5th inst., Dr. L. M. I. Miguault, aged 51.

DEATHS IN BOSTON for the week ending Saturday noon, May 8th, 111. Males, 61—Females, 47.—Abscess, 1—accident, 8—apoplexy, 1—congestion of the brain, 1—disease of the brain, 4—inflammation of the brain, 1—bronchitis, 2—cancer, 2—consumption, 24—convulsions, 2—croup, 2—diphtheria, 2—dropsy, 4—drowned, 2—erysipelas, 1—scarlet fever, 11—typhoid fever, 1—hemorrhage, 2—disease of the heart, 1—intemperance, 1—disease of the kidneys, 3—disease of the liver, 3—inflammation of the lungs, 8—marasmus, 2—measles, 1—paralysis, 3—premature birth, 3—rheumatism, 3—scrofula, 1—disease of the spine, 1—suicide, 1—teething, 1—unknown, 7—whooping cough, 2.

Under 5 years of age, 41—between 5 and 20 years, 16—between 20 and 40 years, 24—between 40 and 60 years, 16—above 60 years, 14. Born in the United States, 82—Ireland, 19—other places, 10.

## AMERICAN MEDICAL ASSOCIATION.

THROUGH the kind intervention of a friend in the Norfolk District of our State, a gentleman of New Orleans has sent us slips from the N. O. *Picayune*, containing a report of two days' proceedings of the Association. The proceedings of the first day, as given below, are from that paper of the 5th inst.

The body of distinguished gentlemen composing the American Medical Association met in the lower hall of the Mechanics' Institute on Tuesday, May 4, at 11 o'clock, A.M., and immediately proceeded to attend to business. The rule of the association restricts the general business of the association to the morning sessions.

Dr. W. O. Baldwin, President, called the meeting to order, and the regular business proceeded. The ex-Presidents of the Association were invited to seats beside the presiding officer. A special invitation was extended to Dr. Warren Stone, of New Orleans, as being one of the most distinguished gentlemen present, and the request was acceded to. Dr. Lopez, an ex-Vice President, was also invited and took his place on the stand.

The meeting was opened with prayer by Rev. Mr. Galleher, of Trinity Church.

Dr. T. G. Richardson, of New Orleans, followed with an address of welcome to the gentlemen of the Association. The address complimented the members on their advances in the science of medicine, surgery, and the general branches incidental to the profession. He paid a pleasant tribute to the amity which is cultivated in this Association. His reference to the general community of interest which binds the members together from all sections of the land, which knows no political differences, and to the stores of our South, with its great floral and medicinal treasures, &c., was received with much applause.

The President announced the programme for the day's proceedings. The committees on surgery and anatomy were appointed to meet in the University Building; on meteorology, medical topography and epidemic diseases, in the Hall of Mechanic's Institute, at 3 P.M.

The nomination of members, by invitation, was pronounced by the President.

The usual annual address followed. This was delivered by the President, Dr. W. O. Baldwin. The address was of a very polished character, filled with references to the excellence of the profession, and the ameni-

ties and courtesies which make it great and noble. Referring to the unity of its interests and aims which keep its members from animosities and sectional differences, he paid a special tribute to the principles which actuate the members of the profession, regardless of aught but humanity and duty. He referred to the sympathies which bound them together in the bonds of a great brotherhood that knew no disruption of its Catholic spirit, during the sorrowful days of war and battle. Amid the shock of arms they stood above the differences that terrified the world with its horrors, the members of the association practising the duties and charities that have ever made the brotherhood noble in all its endurance and christian practices. The remarks were received with much applause and listened to with profound attention.

Among the members and visitors present, we noticed some of the most celebrated and distinguished gentlemen of the profession in the country. Prominent among these loomed up a head taller than those that stood about him—the towering form of Dr. Warren Stone, of our city. The giant intellect of this celebrated man has made a name in the annals of surgery in the South, which is so well known, and has such a wide reputation, that it is impossible for our poor words to add a sentence to the record of his fame.

We also noticed the presence of Dr. H. M. Skillman, of Lexington, Ky.; Dr. Alden March, of Albany, N. Y.; Dr. J. C. Hupp, of Wheeling, Va.; Dr. Thomas McKennan, of Washington, Pa., and many others of note and repute in the profession.

The President referred to a question concerning a change in the system of medical education, which especially claims the attention of the profession as well as the public. The lax method of turning loose on defenceless communities, illy instructed and incompetent physicians, demands a radical change. The system of cheapening the profession and lowering the standard that should be required for excellence and competency, demands careful attention, and is suggestive of prompt and decided action in correcting the system, so that incompetency may no longer rival the worth that opposes intelligence to quackery and ignorance. It is greatly to be hoped that prompt and effective measures may be taken to correct these abuses, that are so greatly calculated to lower the profession, and lessen its influence for good. His reference to books also suggests the idea of too much writing in the profession. The truth is, that the fancy

theories of ambitious writers are too numerous for present use. Altogether, the present system calls loudly for radical change, and we present the eminent gentleman's opinion, hoping it may prove effective in influencing the desirable result.

The assemblage of the Association on their twentieth annual session presented an appearance which comprehends vast intelligence and worth in the profession. The general physiognomy is suggestive of native talent and extensive culture, and almost every individual has marked features that attracts more than ordinary attention. The evident student appearance of the mass indicates that each individual is a man of prominence of either a general or local character. The temptation to individualize is very great, but where there are so many notable names of gentlemen who are prominent in the profession, it would be invidious to attempt the task and leave out any one of the members.

It seldom occurs in the sessions of deliberative bodies which sit in our city, that such profound attention, or such warm energy is elicited, as is exhibited on the part of this intelligent assembly of medical gentlemen.

A feature, which the President referred to regarding a change in the manner of schooling and graduating medical *alumni*, suggests that Federal legislation be invoked to change the present reckless system. The Association evidently was in accord with the proposition to secure governmental interference in lending aid in effecting so desirable a change.

The present facilities, which permit ignorant pretension to assume position in the profession, can only be remedied by the interposition of national legislation, and to it we look eagerly and anxiously for redress and change. How much the community should be interested in securing safeguards in this particular must be recognized by everybody who gives the matter a moment's thought.

A recess of five minutes was proposed, and acceded to by the convention immediately after the close of the able and comprehensive address of the President.

After the meeting was called to order, the letters of absent members were read by the Secretary, Dr. W. B. Atkinson. The letter of Dr. S. D. Gross, of Philadelphia, was first in order. Its broad, catholic and kindly spirit was very handsomely received and applauded. A number of others followed, and all breathed a warm spirit of social amity, as well as devotion to the in-

terests and effectiveness of the convention.

Reports of committees on regularly appointed subjects were called for. Some additions and changes were made to committees. Dr. Antisell was added to committee on cultivation of the cinchona tree.

Several committees failed to report on the special themes which they were appointed to investigate.

On nurse training institutions, Dr. S. D. Gross, of Pa., reported a paper which was referred to committee on practice of medicine.

On commissioners to aid in trials, involving scientific testimony, reported by Dr. John Ordronaux, N. Y.; the paper was referred to committee on medical jurisprudence.

On devising a plan for the relief of widows and orphans of medical men, a paper reported by Dr. John C. Griscom, of New York, was read, proposing a life insurance system, comprehending the mutual life plan. Several other propositions were announced. A peculiar feature was stated to be the fact, that in cities like New York the percentage of life was much more largely in favor of practising physicians than any other class of persons who are engaged in business pursuits. Report adopted for publication.

On Annual Medical Register, a debate occurred with regard to its feasibility and expense. Dr. Packard reported its publication impossible for want of funds.

The Association accepted report of Dr. Mussey, of Cincinnati, Ohio, which proposed that each State Society be requested to furnish a list of its regular practitioners. Accepted and engrossed.

On the best report of treatment for the different forms of cleft palate, by Dr. J. R. Whitehead, of New York. Referred to Surgical Committee.

On medical ethics, reported by Dr. D. F. Condie, of Pennsylvania. Read and received for publication.

The announcement that a meeting of editors of medical journals will be held this morning at 9 o'clock, in the office of Dr. Mitchell, No. 1 Carondelet street, on important business, was changed to the Hall of Mechanics' Institute.

A number of volunteer essays for prizes were accepted and referred to the sections to which they properly belong for disposition.

Report of committee of last year on amendments, was specially referred, to report this morning at 10 o'clock.

Recommendation of Cincinnati Medical Association to appoint certain committees, was adopted.

Received from Waco (Texas) Medical Society, and the Cincinnati Academy of Medicine, communications proposing reforms in the system of medical schooling, and establishing a better standard. Referred to regular committees of the proper sections.

Dr. Paul F. Eve proposed a motion to adjourn until 9 o'clock this Wednesday morning. Adjourned.

*The Reception.*—Last night, the delegates had a formal reception in the small hall of the Mechanic's Institute, on which occasion a collation was bountifully provided for the guests, of whom there were a very large number present. A large supply of strawberries and ice cream was disposed of with great enjoyment, especially by those of our visitors from Northern latitudes, to whom these would have been a rarity at home for a month or more to come. The honors were gracefully paid to the guests by the gentlemen of the reception committee and the citizens who were present.

A considerable number of ladies were also present, and graced the pleasant scene with their countenance. These were especially toasted and received due attention from the members.

The assemblage comprised a much larger number of the profession than were present at the session of the convention, which assembled to attend to business yesterday. Festivities are, doubtless, ever more agreeable than dry details of reports and business.

#### SECOND DAY'S PROCEEDINGS.

(From the New Orleans Picayune of May 6th.)

The attendance yesterday was much larger than on the first day. A number of arrivals had increased the *personnel* of the Association to near three hundred. The hall was well filled; and the same dignified deportment which had marked the deliberations of the members on the opening day was displayed on the second day. Besides this, the individual members having become better acquainted with one another, and with parliamentary forms, went more briskly to work, and covered a larger ground of practical debate. Much of the facility with which the deliberations were conducted yesterday, and the promptness with which action was taken upon the various resolutions, was, undoubtedly, due to the tact and practical administrative knowledge displayed by President Baldwin.

At 9, A.M., Dr. W. O. Baldwin, the President, in the chair, called the meeting to order. The reading of the minutes having

been dispensed with, Dr. Richardson, Chairman of the Committee of Arrangements, presented the names of the following candidates for admission, by invitation, to the Association, who were duly elected:—

Dr. Jas. E. Morris, New Iberia, La.; Drs. Wm. H. Watkins, John M. Cullen, Charles H. Kelly, S. R. Hurd, C. J. Beckham, P. B. McKelvey, Wm. G. Austin, J. Bensadon, O. Anfonx, H. D. Schmidt, Fr. Loeber, S. A. Smith, of New Orleans; L. L. Henry, Henderson McFarland, J. S. Bacon, of Mississippi; Dr. C. Tucker, of Danville, Ky.; and Drs. Florence O'Donnoghue and John F. Randolph, of the U. S. A.

A paper on "Canula and the New Mode of applying Ligatures," was submitted by Dr. P. F. Eve (Tenn.), and was referred to the Section on Surgery.

Dr. J. M. Bush, of Kentucky, offered the following resolution:—

*Resolved*, That a committee of five members be appointed by the chair, to take into consideration the subjects alluded to in the President's address, and report at this meeting.

This resolution having been adopted, the President selected as members of the committee Dr. Parvin of Indiana, Chairman; Dr. Toner of the District of Columbia, Dr. Pollock of Pennsylvania, Dr. Welch of Texas, Dr. Seeley of Alabama.

Dr. McPheeters, of Missouri, offered a communication from the Medical Society of that State, in reference to medical education.

On motion of Dr. Toner, District of Columbia, it was referred to the special committee on that subject.

Dr. Eve offered the minutes of the Medical Society of Tennessee, which was similarly referred.

Dr. Gaillard, of Kentucky, offered the following preamble and resolutions, which were referred to the same committee:—

WHEREAS, The medical teachers of America have, after a trial of twenty-two years, failed to meet satisfactorily and efficiently the requirements of the great body of the profession in regard to medical education; and

Whereas, the condition of the profession is yearly becoming more deplorable on account of the antagonistic and objectionable policy of medical schools in making the amount of fees charged, rather than a successful teaching, the basis of competition; and

Whereas, to obtain professionally competent graduates, sound and efficient teachers are indispensably necessary; and

Whereas, such teachers, to be found throughout the country, cannot be induced to leave their homes without assurance of competent remuneration; and

Whereas, such remuneration can only be obtained by adequate fees charged, unless by a system of low fees the number of students be relied upon to make up the inevitable pecuniary deficiency; and

Whereas, reliance upon numbers of students for this purpose deplorably crowds the already overcrowded professional field, diminishing thereby individual income, judgment, experience and skill, thereby compelling practitioners to resort to other avocations as a source of supplemental income; and

Whereas, this devotion to other pursuits destroys opportunities for study and improvement, degrading thereby the status and standard of American physicians; and

Whereas, the schools of New England, New York, Pennsylvania, Maryland, Virginia, South Carolina, Georgia, Alabama, Texas, Tennessee and the District of Columbia now charge comparatively remunerative fees; and

Whereas, the low system of fees is charged only in a few of the Middle States, and can with advantage be made to conform to the rate of fees charged elsewhere; and

Whereas, it is as unethical for colleges to underbid each other pecuniarily as for practitioners to do so:—

*Resolved*, That hereafter no medical school in this country, other than those fully endowed, be entitled to representation in this Association, if the amount charged by such schools for a single course of regular lectures be less than one hundred and forty dollars.

*Resolved*, That all schools charging less than this sum are earnestly requested by this Association to advance their rate of fees to the amount mentioned.

The report of Dr. Lee, of New York, the delegate to the Association of Superintendents of Insane Asylums, was offered and referred to the Section on Psychology.

The report of Dr. Gross, of Pennsylvania, delegate to Foreign Medical Association, together with the letter to Dr. Ehrenberg, was read and referred to the Committee of Publication.

The time having arrived for consideration of the revision of plan of organization, it was, on motion, taken up, and certain changes were adopted.

A recess was taken to allow the selection of members of the Committee on Nominations.

On reassembling, the Permanent Secretary announced the following as the Committee on Nominations:—New York, J. C. Smith; Delaware, H. F. Askew; Pennsylvania, A. M. Pollack; Kentucky, H. M. Skillman; Tennessee, J. B. Lindsley; Mississippi, W. Y. Gadbury; Alabama, J. Cockran; Ohio, J. No. Townsend; Indiana, B. S. Woodworth; Illinois, T. D. Fitch; Wisconsin, H. Van Dusen; Missouri, J. S. Moore; Michigan, J. B. White; Georgia, R. D. Arnold; Louisiana, S. Logan; Texas, S. M. Welch; Minnesota, C. N. Hewitt; Arkansas, R. G. Jennings; West Virginia, W. J. Bates; Rhode Island, G. L. Collins; District of Columbia, L. W. Ritchie; United States Army, J. J. Woodward; United States Navy, F. E. Potter.

Dr. Chaille, of Louisiana, submitted a proposition for a common medical nomenclature in the United States, taking as a model an official publication on the subject by the Royal College of Physicians of London, and offered the following resolutions, which were adopted:

*Resolved*, That a committee of five be appointed by the President, to report, as soon as practicable, to the present session of this Association, upon the following:

1. The propriety of adopting, and using its influence to have adopted, by the entire medical profession in the United States, the provisional "Nomenclature of Diseases of the Royal College of Physicians."

2. On the practicability of having this nomenclature published in such manner as may render it easily and cheaply accessible to every member of the profession.

3. To recommend such other practical measures for the action of this Association as may be necessary to introduce this nomenclature into official (military, naval, &c.) and general use.

The Chair appointed the following gentlemen as the committee: Drs. Woodward, U. S. A., Heustis, of Alabama, F. G. Smith, of Pennsylvania, and Chaille, of Louisiana.

The reports of the Committee of Publication, and the Treasurer, were read, accepted, and referred to the Committee of Publication.

On motion the Committee on Nominations were permitted to retire for consultation.

The special order for 12 being the report on Specialists, it was read by the Secretary, and, on motion of Dr. Sayre, the resolutions were adopted and the report referred to the Committee of Publication.

### CASE OF EMBOLISM OF THE EXTERNAL ILIAC, FOLLOWED BY GANGRENE, LOSS OF LEG BELOW THE KNEE, AND RECOVERY.

Read before the Boston Society for Medical Improvement May 10th, 1869, by GEO. H. LYMAN, M.D.

On the 28th of Dec., 1868, I was requested to see Dr. —, a professional gentleman of this city, 63 years of age. I found him suffering apparently from a slight but decided attack of pleuritis. The only unusual symptom was an irregularly intermittent pulse, the intermissions generally occurring once in five or six beats, with occasionally the lapse of a minute or more with no intermission. Careful auscultation revealed nothing abnormal in the cardiac impulse or sounds; cough moderate—no dyspnoea when quiet. His chief complaint was of severe pain in the right hypochondrium, and this was greatly aggravated by movement or full inspiration. My notes of the case continue as follows:

29th.—Cough has been slightly tinged with blood. Has suffered much annoyance during past 24 hours from cold perspiration.

30th.—At the bottom of the right pleura posteriorly there is marked dullness on percussion, and decided diminution of vesicular respiration. The eighth day, i. e. Jan. 5th, 1869, the patient was reported as convalescent, being free from pain and in every respect comfortable. The treatment, it may be added, consisted of rest in bed, warm fomentations and moderate opiates.

At 3 o'clock on the following morning, Jan. 6th, I was summoned again in haste, with the statement that a shock of paralysis had occurred. On examination I found entire loss of motion and nearly complete loss of sensation in the foot and leg to within a few inches of the knee, with marked diminution of temperature in the affected parts—pulsation perceptible in the anterior tibial—some pain in the calf of the leg, but this last, it is noteworthy, was not an urgent symptom unless the limb was moved.

VOL. III.—No. 16

Pressure and the application of a hot sponge to the spine, revealed decided tenderness about the lower lumbar vertebræ. There was some contraction of the pupils and very perceptible mental confusion, as if under the influence of an opiate. Upon inquiry it was found that one-half an ounce of tinct. of opium had been taken in divided doses during the night for the relief of the pain.

In connection with this state of things it should be here observed that the patient had been in Europe from September, 1867, to November, 1868, and that in Dresden, in November, 1867, he had an obscure attack of pain in the back, with loss of power in the right leg, lasting some ten days. There was also considerable swelling, which with the pain continued for months, and recovery was not complete for a year.

It should also be noted that many years since he was under the charge of the late Dr. James Jackson, for some obscure but painful spinal disorder resulting from a sprain, and which it was feared at the time might eventually terminate in paralysis.

6, P.M.—He complains of increased pain in the limb during the day. Temperature of the foot about the same. Pulse still felt in the anterior tibial.

7th.—Has passed a restless night, with great pain, or, as he calls it, an indescribably distressing feeling of bursting or weight in the foot and calf. There is now also extreme tenderness over the course of the vessels as far as the groin, with discoloration especially marked about the nails. No pulsation to be felt below the left common iliac.

8th.—The discoloration and coldness now extend to within a few inches of the knee, the color varying from the dark purple about the toes, mottled dark yellow about the instep and ankle, fading gradually to the above point, to which the loss of sensation was traced at first. Here a faint red line, extending irregularly around the limb, forms the present limit of the disease. Below this the prick of a pin is not felt unless perhaps, doubtfully, over the instep and some parts of the tibia.

[WHOLE No. 2151.]

9th.—Pulse 104. It has varied heretofore from 84 to 90. He was moved yesterday three miles into the country.

10th.—There is some modification of the temperature, the dorsum and inner aspect of the foot being less cold.

11th.—The dorsum and inside of the foot are of nearly natural temperature. The track of the vessels in the thigh is still tender, but less so. Pulse 76 and good. To this date the treatment has consisted of anodynes, of which ten drops of the liquid extract of opium sufficed to quiet pain and restlessness, enemata and small doses of comp. cathartic pill; for the past four days belladonna and ergot have been given. The foot has been surrounded by dry warmth.

12th.—Had a restless night, with mutterings in the sleep, and a tendency to subsultus. Pulse 104. He is evidently much more feeble. Less warmth of instep than yesterday, but still it is not cold, like the rest of the limb. The prick of a pin is decidedly perceptible over the lower end of the metacarpal bones. He was ordered milk punch and concentrated broths, as much as could be relished.

13th.—To-day there is unmistakable pulsation in the femoral artery, below Poupart's ligament, but very feeble, and not synchronous with the heart pulsations, there being but 20 beats in a minute, the latter being 84. The following day this femoral pulse was more difficult of recognition, though still perceptible.

15th.—The femoral pulse has wholly disappeared. Large bulke filled with discolored serum have arisen over the upper part of the gastrocnemius. Pulse 104, and more feeble. Stimulus to be increased.

25th.—Has continued much the same during the past ten days. The shrivelling and discoloration have increased over the foot, which is now dry and black to the ankle. The whole surface of the leg is dark and vesicated, discharging freely of bloody serum, not particularly offensive. Ulceration has commenced at the line of demarcation. Some suspicious spots, livid and tender on pressure, have appeared over the patella.

27th.—During the past forty-eight hours there has been severe pain in the lower part of the rectum, with loss of power over the anal sphincter, and the result of this want of control is the occasion of constant discomfort and annoyance. The tenesmus is extreme, with the feeling of some foreign body in the rectum. Nothing discoverable

upon examination. Pulse 112. The patient is much prostrated, and his general appearance decidedly less favorable, though he remains tranquil and confident in what he calls "his reserved stock of vital force." The pain and tenderness over the track of the vessels in the thigh have nearly disappeared, though a tender mass of induration still remains below Poupart's ligament, and in the popliteal space. The spots upon the patella have diminished.

Feb. 4.—The tissues of the leg are becoming more black and dry until near the line of demarcation, where they are decidedly pulsatious and extremely offensive. Suffers still severely from pain in the rectum above the sphincter during his evacuations, which are now, however, not so constant. During the past twenty-four hours the restlessness and want of sleep have been marked. He takes the liquid extract of opium in varying quantities from 40 to 70 drops. General aspect less favorable. The nourishment and stimulus are continued as largely as the stomach will bear. For the first time seems discouraged and depressed. Directed the opiate to be increased sufficiently to quiet the restlessness.

6th.—Pulse 84. Has taken 150 drops of the opiate in 24 hours. Shows some disinclination for food.

13th.—The loss of appetite fortunately proved to be but temporary. During the week has taken largely of beef tea, eggs, porter and rum, with from 150 to 180 drops of the opiate daily. His digestion remains as from the beginning, perfect, but his strength is less. The fecal evacuations continue troublesome at times. The ulcerative process has extended to the fascia all around the limb, which is enveloped at this point in a charcoal poultice. Carbolic acid, chlorinated soda, &c. &c., are freely used, but nothing avails to subdue the odor, which is extremely offensive and permeates everything.

18th.—The line of separation is rapidly deepening posteriorly. Pulse 86 and digestion good, but he still loses strength. Requires 200 to 300 drops of the opiate daily.

Mar. 1.—The tibia is now felt posteriorly between the muscles. The dead tissues are broken down and rapidly separating. Paralysis of the anal sphincter continues to cause extreme annoyance. Some low delirium during sleep and at first waking. Perspiration abundant also at those periods. Pulse 90 and fair in strength, but on the whole he is not so strong as a fortnight since. A small, oblong gangrenous patch,

involving the thickness of the skin, has appeared on the outer thigh, four inches above the knee.

9th.—The upper part of the diseased portion being completely pultaceous and intolerably offensive, the bones were divided six inches below the patella, so as to avoid any possible interference with the sound tissues. The spot upon the thigh is cicatrizing, and looks as though cut out with a punch.

12th.—The removal of the limb has proved beneficial in every way, improving the atmosphere, disposing of an awkward weight, and facilitating the application of dressings. The sloughy mass remaining in the centre of the stump and penetrating it irregularly, is rapidly melting away, leaving healthy granulations behind. Substituted to-day for the poultice a dressing of earth. The fecal evacuations are becoming less unmanageable, occurring with tolerable regularity once in two days only. Requires about 320 drops of the opiate in 24 hours. The attendant has standing directions to give enough to remove restlessness and the sense of prostration. On one occasion, a few days since, four ounces was needed in the 24 hours to secure this result, and the following day he was in every respect more comfortable.

18th.—Improved daily until yesterday, but has had a wretched night, with restlessness and constant hicough, and he is threatened also with a bed sore upon the sacrum. Pulse 90 only and fair. Insisted upon the liquid opium to the extent of 6 oz. (by measure) in the last 20 hours. Ordered chloric ether and camphor, with an increase of the bark and wine. There is but little diseased tissue remaining. The earth dressing is very satisfactory, but from the nature of the surface it is difficult to apply without too much weight. The parts have retracted and the edges are rapidly drawing in, leaving the bones protruding 2 or 3 inches.

20th.—Has taken 5 ounces of opiate in last 24 hours. The hicough ceased yesterday, and the bed-sore is less threatening. Has resumed the charcoal dressing as more convenient. There is a marvellous improvement in his general appearance and strength. Begins to recover some control over the paralyzed sphincter. Has been lifted into a wheel chair for a short time without excessive fatigue.

29th.—The stump is wholly free from gangrene, and union is now prevented only by the protruding bones. Has comfortable nights, and steadily gains in strength. Has been several times in wheel chair with

advantage. He still requires  $2\frac{1}{2}$  drachms of liquid opium every four hours, night and day, and occasionally an extra dose is required. Attempts made to diminish the quantity are always followed by restlessness and prostration.

April 2.—Have succeeded in reducing the opiate to  $\frac{3}{4}$  iss. per day. Complains a little of dyspepsia, but is decidedly stronger. Gets to his chair with facility. I advised to diminish the amount of liquid food taken.

9th.—Steadily improving. Has been unable during the week to reduce the opiate. He declines, and, as I think, wisely, any operative interference for the present with the protruding bones, though but for them the wound would close immediately. An irregular flap of skin extends over the front of the tibia, but its fibular surface is denuded  $3\frac{1}{4}$  inches.

19th.—The opiate has been gradually reduced to six drachms in the 24 hours. Has recovered his control over the sphincter.

May 2.—The opiate is now reduced to four drachms, distributed through the 24 hours. Under the use of bark and pyrophosphate of iron is steadily gaining in strength, and with the aid of crutches or chair he is able to move about without much difficulty.

Daily details of treatment have seemed unnecessary. From the commencement the manifest indications were to sustain the strength and use no medication which should cause even temporarily any disturbance of the digestive organs when possible to avoid it. The necessity for anodynes originated with the disease. At first mild laxatives were required, and belladonna and ergot were employed for a short period, but probably with little or no influence upon the result, for all that part of the limb ultimately lost was really dead within forty-eight hours of the attack, and the limit then attained was never exceeded. Enemata, ether, camphor, sulph. acid, &c., were used as required to meet different indications, and dry warmth was kept constantly applied to both limbs. Large quantities of strong tincture of bark were taken throughout the whole period, about 8 ounces daily of old Medford rum, and as much strong beef tea as could be assimilated. So far as any drug influenced the result, opium seems to me to have been the most effective. Beginning early with only 10 drops of the liquid extract,\* which at that time was sufficient to produce a decided anodyne effect, at the

\* Prepared by Smith and Melvin, and of the full strength of the official tinct. of opii, equivalent to 4 grs. of morphine to the fluid ounce.

end of a month (Feb. 6th) 150 to 180 drops daily were used, and from that time the quantity had to be rapidly increased, until in the middle of March we find that 4 ounces were used in one day, at another time 6 ounces. During the last month the usual dose was from 2 to 3 drachms every 4 hours, and nothing less than that sufficed to keep the pulse strong. (It should be mentioned here that the patient had never been in the habit of using opium in any form.)

The remarkable effect of opium upon the vital powers, stimulating the heart and giving tone to the capillaries, especially in advanced life, is well known, and the remark attributed to Sir Benj. Brodie, that the difference between recovery and a fatal result in cases of this form of gangrene of the extremities depends upon the toleration by the patient of opium, receives additional confirmation by the details of this case. With every increase of the dose there was an evident amelioration of the restlessness and prostration. Another marked feature was the absence of any gastric disturbance. Though the amount of food and stimulants taken was unusually great, after the first week the assimilative processes were never disordered, the digestive functions being as regular and natural as in perfect health.

With regard to the earth dressing, I think it would have been of advantage, if used earlier, in removing fætor and stimulating the ulcerative process; and were a similar case to occur to me, I should keep the soft parts at the line of demarcation buried in dry earth from the beginning. The practice is a novel one in this vicinity, and my attention was not called to it until late in the case. It has been used extensively by Dr. Hewson, of Philadelphia, who states that he has "had extraordinary success with it, even as a primary dressing in amputations and other major operations."\*

Arrest of the circulation, resulting in that form of gangrene exhibited in this case, may be induced by various pathological causes, viz.: the obstruction may arise in a perfectly healthy vessel from a fibrinous mass originating at some distant point, as when a vegetation is dislodged from the cardiac valves, or a clot from diseased aorta, or from blood poisoning, or it may be caused by a narrowing of the vessel at the point obstructed, as by the pressure of a tumor, by arteritis, atheroma, ossification,

rupture of the inner coats, &c. Indeed, any local disease or obstruction of an artery sufficient to diminish the blood-current without being in itself an immediate source of danger, may, after acute inflammation in some distant part, inducing hyperinosis, or that state of the blood in which the fibrin becomes relatively in excess, cause a separation of the fibrin from the current at the point of obstruction, until its accumulation closes the vessel, or becoming detached, is carried on to some subdivision too small to permit its further passage. It is also asserted by Mr. Bence Jones (*Med. Times and Gazette*, vol. i. 1866) that in diseased arteries, the diminished force of the blood-current beyond the point diseased may cause gangrene. In such a case, however, it is questionable whether the capillary obstruction is not due to minute particles of fibrin, rather than to diminished force of the current merely. Cruveilhier (*Anat. Pathol.*, tome ii. liv. 27) observes that ossification of the larger vessels may result in no obstruction, but that when it exists in the smaller vessels gangrene results, and he quotes Dupuytren's assertion that arteritis, when sufficiently severe to arrest the current entirely, is the most frequent cause of senile gangrene. He objects to Legroux's theory that the arteritis is not the cause of the clot, but is caused by it, adding that no sanguineous vessels are found in the lining membrane, the redness and apparent injection perceived being merely "coloration by impregnation." He acknowledges that the blood may be "the vehicle of the cause" of the inflammation, but that coagulation follows and does not precede the latter. In a valuable paper by Mr. Savory "on the local effects of blood poisoning in relation to embolism" (*St. Bartholomew's Hospital Reports*, vol. i. p. 107) a series of experiments are detailed, showing the effect of the injection of solid particles suspended in water, and of putrid fluids upon the capillary circulation; and though the subject of pyæmia is there more directly involved, still the analogy between arterial and capillary embolism is so obvious that a reference to the paper will be found interesting to any one investigating this subject.

The paper of Dr. Kirkes (*Med. Chir. Trans.*, vol. xxxv. p. 281) "on the effects resulting from the detachment of fibrinous deposits from the interior of the heart," also one by Mr. Tuffnell (*Dublin Quarterly Journal of Medical Sciences*, vol. xv. 1853, p. 371) "on the influence of vegetation on the valves of the heart in the production of secondary arterial disease," prove conclu-

\* In a note kindly sent me from Dr. Hewson in answer to some inquiries, he says:—"The kind of earth I have found answer best is that containing the most clay and least sand. It should be thoroughly dried and finely sifted," and "must be removed as soon as it becomes saturated."

sively that fatal obstruction may occur suddenly in perfectly healthy vessels.

Many cases, on the other hand, are reported where the obstruction was due to local causes. Among others Dr. Gordon (*Dublin Quarterly Journal Medical Sciences*, vol. xxxiii. 1862, p. 340) gives a case of extensive fatty degeneration in a boy only 14 years of age, the obstructed circulation resulting in death from gangrene. In this case, although the heart was unsound, the gangrene of the extremity was manifestly due to the atheromatous condition of the vessels.

A well reported typical case is also given by Mr. Annandale (*Edinburgh Medical Journal*, Apr., 1863, vol. viii. p. 904). Here the heart was perfectly healthy, but gangrene extending to the knee proved fatal. The obstruction was in the femoral artery, and caused by the detachment of a clot from above, the lower portion of the aorta being atheromatous, and containing adherent clots, the femoral at the point of obstruction being perfectly healthy. Appended to this case is a short summary of the views of various authors upon the mode of formation of the obstructing clot. A singular case of rupture of the inner and middle coats of the iliac in an atheromatous subject, is reported by Mr. Spence (*Edinburgh Medical Journal*, July, 1864, p. 7), in which the blood dissected its way upwards beneath the inner coat, instead of downwards in the direction of the current—resulting in closure of the vessel.

A series of instructive cases, illustrative of the different forms of arterial obstruction, is given by Prof. Simpson, of Edinburgh (*Obstetric Works*, vol. ii. p. 34).

The most extensive and satisfactory experiments upon the separation of fibrin that I have had access to are those of Mr. Richardson, in his "Essay on Coagulation of the Blood," London, 1858. He observes (p. 29) that "most writers are agreed that the fibrin is actually or relatively increased in acute inflammation; in pregnancy, in plethora, albuminuria, and in some instances where great loss of blood has taken place;" also—p. 35, "that in some cases where the blood-current is impeded, as in aneurism in the heart when the valves are rigid, or in very feeble states of the heart, the fibrin has a tendency to separate from the other blood constituents at the point of obstruction, and to form itself into distinct masses—fibrinous concretions." The result of his own labors and a review of the arguments and facts of a large number of authorities, is (p. 37) "1st, that the blood may, in

very rare instances, coagulate in the ordinary way, i. e., as a red clot, in the body during life; 2d, that the fibrin alone may separate in the form of concretions during life; this result being theoretically attributable, (a) to mere slowness of motion, as in aneurismal tumor, and as in some cases of slow deaths; (b) to absolute or relative increase of fibrin itself; (c) to a peculiar kind of coagulation arising from chemical or physical changes incident to the mixture of some poisons, as pus, with the blood; (d) to the neutralization of those alkaline constituents of the blood, which hold the fibrin in chemical solution, by some free acid, as lactic, generated in the body superabundantly; (e) to an extreme tenuity of the serum in which the fibrin is distributed, with a feeble resistance against the natural attraction of the molecules of the fibrin and their consequent aggregation; (f) to a supposed disorganization or disintegration of the blood, under the influence of certain diseases, as typhus and scurvy, whereby it has a tendency to divide into its constituent parts."

Of the diagnosis of gangrene from arterial obstruction, it may be said that in cases arising from the sudden impaction of a clot in the large vessels supplying the extremities, a very short time suffices to clear up any doubt, the death of the part being too evident to be long mistaken. The sudden loss of sensation and motion may at first sight lead one to suppose that it is paralysis from lesion of the nervous system with which he has to deal. Such was certainly my own impression with this patient at first view, and until at the succeeding visit the real nature of the case became apparent.

Cruveilhier's report of a similar experience (*Anat. Path.*, tome ii. liv. 27) is constantly alluded to by writers. He says: "It sometimes happens that complete paralysis of a member, with no discoloration of the skin, precedes by several days the physical signs of gangrene," followed by a detail of such a case occurring to himself. He lays stress upon the fact that in paralysis from obstruction the loss of sensation and motion is *complete*,\* which is rarely the case in paralysis from nerve lesion, and gives as other pathognomonic characters of the former, the pain, coldness, discoloration, cessation of pulsation, and tenderness

\* In my case there were parts of the limb in which the loss of sensation was not *complete* for many days, but the greater part was dead, as it were, from the beginning, and not merely partially benumbed, so that Cruveilhier's distinction between them doubtless holds good.

and hardness in the course of the vessels. He considers the extreme pain to be due not necessarily to inflammation, but to a kind of struggle between life and death in the parts deprived of their material of nutrition—"mais d'une sorte de lutte qui s'établit entre la vie et la mort dans les parties privées de leurs matériaux de nutrition."

Dr. Gordon (*loc. cit.*) considers the pain to be "caused in all probability by the excessive sudden distention of the coats of the artery behind the occlusion." Were this the case, however, we might expect pain at the seat of this distention. In his own case the obstruction was in the iliac, but the pain in the calf of the leg. In the case I report, no pain or tenderness was felt higher than the femoral, but in the leg only, and such is the history of most of the recorded cases. Another fact noticeable in my own case, and repeatedly alluded to by others, is that the pain was aggravated by any local disturbance from pressure or touch. No entirely satisfactory explanation of the cause of the pain has yet been given. An interesting discussion of this point may be found in the July number of the *Edinburgh Medical Journal*, 1864, p. 10.

Of the cause and exact nature and seat of the obstruction or embolus in the case now reported, the uncommon result in recovery leaves, happily, room for conjecture; but careful consideration of its history, the absence of any recognizable valvular lesion of the heart or ossification of the vessels, do not permit me to doubt that it was due either, 1st, to an atheromatous condition of the arteries and giving way of the inner coat at the point of obstruction; or, 2d, to fibrinous clot or embolus, the result of hyperinosis caused by the pleuritis which was immediately antecedent. The age of the patient, and the intermittent pulse, so indicative of weak muscular action of the heart and possibly incipient fatty degeneration of its tissues, might well be coincident with atheromatous disease of the vessels; also the previous attack in Dresden, which it now seems possible was due to partial suspension of the circulation in the right leg, and which was not preceded or accompanied by any marked febrile or inflammatory symptoms, would all point to the first of the causes indicated, while, on the other hand, the suddenness of the attack and the immediately preceding pleuritis—recognized by authors as one of the most frequent antecedents of embolus—both point to the latter supposition. However this may be, the seat of the obstruc-

tion appears to have been unquestionably in the external iliac, at or near its origin. If above that point, the gangrene would hardly have been limited to the parts below the knee. The temporary paralysis of the sphincter, confined possibly to its left half, may have been due to smaller particles of fibrin descending the internal iliac and occluding the hæmorrhoidal branches of that side.

The slight return for a few days of pulsation in the femoral, and also of warmth to the foot, have been noticed in a few other reported cases. The explanation is not clear, but the phenomena were probably due to some temporary softening or displacement of the obstructing body, or possibly enlargement of the artery itself, permitting for a short period the passage of an insufficient current of blood.

---

#### ON PARALYSIS OF THE MOTOR NERVES OF THE EYE, WITH CASES OBSERVED IN THE CLINIQUE OF PROFESSOR VON GRAEFE.

By A. KESSLER, M.D., of Hartford, Conn.

THE most frequent and prominent symptoms of paralysis of the ocular muscles are strabismus, diplopia, ptosis, mydriasis, impairment of accommodation and luscitas, presenting either separately or collectively the various conditions of that complex affection. Paralysis leads necessarily to material and functional changes in the muscular apparatus, which destroy the natural correspondence of the optic axes, the parallelism of the horizontal and vertical diameters and the coincidence of the centres of revolution of the two eyes, and thus give rise to strabismus and diplopia. But although strabismus forms invariably a very prominent symptom in the more advanced stages of paralytic disease, and although a very close causal connection exists between them, yet the former prevails independently of paralysis, inasmuch as it originates from a great many other causes—too numerous to specify here—such, for instance, as anomalies of refraction, incongruence of the two retinæ, opacities of the cornea and in the refractive media, intra-orbital tumors and abscesses, penetrating lesions, inflammation of the muscular apparatus, &c. If uncomplicated with faulty innervation, perverted nervous action, and all the like, if merely dependent on impaired functional capacity, insufficiency and structural disorders, then it must be distinguished from the form connected with

and owing to paralysis of the muscles. In pure concomitant strabismus, where the motor nerves are perfectly intact, and where no secondary atrophy has taken place in the muscles at fault, the deformed eye accompanies all the movements of its partner; not so in paralytic strabismus, where the mobility of the affected eye is impaired in proportion to the intensity and extensive nature of the disease. Although both are equally characterized by loss of the natural correspondence of the optic axes, the deviation in the former is nearly constant, and the bulbi themselves are but little restrained in their associated movements, while in the latter the deviation changes according to the degree of the paralysis, and the eye, being impaired in its excursive capacity, remains fixed more or less immovably in one direction. In pure strabismus the primary deviation of the squinting eye is as great as the secondary of its sound associate, or, in other words, the primary and secondary strabismic angles are the same; in paralytic strabismus, on the contrary, the secondary deviation of the healthy eye is much greater than the primary of the one affected, and the sum of mobility of both bulbi is not the same, but decreased in the diseased eye towards the paralyzed muscle. Want of harmony in the movements of the eyes is the chief characteristic of the former; loss of motion distinguishes the latter.

The complication with binocular diplopia is, under ordinary circumstances, an exception in pure strabismus, for the reason that the false image is usually suppressed or rather unnoticed, by the patient giving his undivided attention to the sensations of the healthy eye; the impressions on this being much more vivid, the mind perceives the stronger to the exclusion of the weaker. Although diplopia arises from various causes, the proximate cause is most frequently paralysis of some one or more of the muscles of the eyeball; and in paralytic disease of the motor apparatus it plays indeed a very important part, being one of the most, if not the most, conspicuous and troublesome symptoms. Diplopia does not take place in all parts of the visual field, but is confined to the path of the paralyzed muscle; and its greater or less extent, although chiefly dependent on the amount of paralysis present, varies with the influence of other very important conditions, such as the capacity of fusion, the power of accommodation, the refractive state of the eye, &c. As at times the deviation of the axes and diameters of the

eyes is caused only by an adjustment for certain distances and in particular directions, so does diplopia in such cases become manifest only when the patient looks at those distances and in those directions; and the double images will appear either homonymous or crossed, according as there is a pathological convergence or divergence of the visual axes. The relative situation and position of the double images most generally indicate the seat of the affection, and the greater the distance between them the more decided is the paralysis. Whenever the difference in the distance of separation of the double images is found equal and constant, the diplopia is not due to paralysis; that alone causing the discrepancies in their relative distance from each other. (*Die Differenz der Drehungsbögen und Willenskkräfte ist bedingt durch Lähmung.*—v. Graefe.)

The binocular double vision, which originates from muscular and nervous derangements and attends pure and paralytic strabismus, must be distinguished from the monocular diplopia and polyopia, owing to disorders in the dioptric organs and frequently accompanying ametropia and irregular astigmatism; they are mere circles of dispersion, and easily corrected by spherical and cylindrical glasses, or a combination of both, according to the nature of the anomaly of refraction.

Paralysis of the muscle supplied by the abducens, or the rectus externus, is marked by a more or less complete incapacity of the bulbus to be turned outwards; by homonymous, horizontal double images, which become more separated from each other the more the eye is turned in the direction of the paralyzed muscle, and which diverge obliquely upwards as the eye is directed outwards and upwards. In order to avoid the troublesome double vision, patients turn the head towards the side of the affected externus muscle, and thus get the object in a relatively favorable situation for the adjustment of both eyes.

Paralysis of the muscle supplied by the trochlear nerve, or the superior oblique, is characterized by homonymous double images, confined to the lower field of vision, and becoming further separated from each other in the vertical meridian the more the eye is directed downwards. The two images converge upwards and grow more oblique if the object be moved towards the affected eye; the vertical distances of separation, on the contrary, decrease in the direction of the affected side and increase towards the sound eye. The

false image appears nearer and below the true one, only on looking very much downwards, it stands higher.

In paralysis of the muscles supplied by the oculomotor nerve, viz., the internal, superior and inferior recti, the inferior oblique, the levator palpebrae superioris, the ciliary fibres of the iris and the ciliary muscle, the symptoms vary very much according to the degree and extent of the affection. If the paralysis is complete, ptosis of the upper eyelid, and for the most part, too, a slight prominence and eversion of the bulbus become apparent. The mobility of the eyeball is normal in the horizontal equator, on account of the healthy externus, and outwards and downwards in the path of the sound trochlear muscle, but in all other directions either restrained or wholly lost. With the exception of the regions just named, diplopia takes place in all parts of the visual field; crossed double images—the illusory higher—which converge upwards and appear with the upper end nearer to the eye. The lateral distance of separation of the images increases with the amount of deviation of the object towards the healthy eye, but the difference in their attitudes augments with the movement of the object above the horizontal *equator*, and decreases as it descends below it. The obliqueness of the images is greater above than below, and reaches its maximum when the eye is directed upwards and outwards. The rigidity, immobility, and moderate dilatation of the pupil point to a paralytic condition of the sphincter, or circular fibres of the iris, while the impairment or loss of accommodation indicates that the ciliary muscle, or tensor choroideae, is also implicated. . . . .

With the loss of their contractile power and the cessation of their functions, mydriasis and paralysis of the accommodation ensue; the range of the latter indicates to what extent the tensor choroideae, as Brücke has styled it, is involved, and the smaller it is found the more developed is the paralysis. Another quite frequent and distressing symptom in paralysis of the muscles, supplied by the third nerve, is vertigo, which patients try to avoid by looking and leaning the head to the non-affected side.

Paralysis of the ocular muscles, almost always a mere symptom in various morbid conditions, originates from causes that are either of central or peripheral, of constitutional or local nature. Basilar meningitis, cerebral neoplasms, cranial periostitis, intraorbital abscesses and tumors, spinal disease, rheumatic inflammation of the nerve-

sheaths, syphilitic cachexia, circulatory disorders, mechanical lesions of the motor nerves, &c., are among its chief causes; but it would lead us too far, to dwell at length on the various combinations of that complex affection, their characteristics and differential diagnosis, and this bare enumeration must therefore suffice—with a few accompanying remarks only.

The paralytic disease may be confined to a single muscle, or may attack several, more or less completely, at the same time; it may furthermore be limited to the boundaries of the nerves, supplying the muscles of the eyeball, or be complicated with a similar affection of the facialis, trigeminus, &c., and it is obvious that all these various conditions depend solely on the relative seat and extent of the primary cause. A complete paralysis is usually peripheral, and although partial ones may be also of the same character, they are much oftener of central origin—in that case not all the nerve-fibres becoming involved. Those forms, therefore, which precede or accompany cerebral and spinal disease, are easily distinguished from the simple rheumatic and traumatic by the fact that the latter are invariably more constant and complete. Among the former deserves especial mention the paralysis attending locomotor ataxia, of which it forms one of the first and most essential symptoms. The later stages of that insidious malady are marked by a total paralysis of the third pair, in consequence of degeneration of the nerve-fibres; but this grave complication must be distinguished from the ephemeral paralytic affection of the abducens in the initiatory stage. It appears at first as pure diplopia only, which vanishes sometimes very rapidly, and is later followed by symptoms of a more decided palsy.

The course and termination of any paralytic disease involving the muscular apparatus of the eye depend chiefly on the nature of the pathogenetic cause, on the presence or absence of complications and the degree and duration of the affection. Peripheral cases, due to rheumatic inflammation of the nerve-sheaths and other acute morbid processes, arise suddenly and develop often in the course of a few hours; while those of central origin, owing to organic disease of the brain and spine, to constitutional cachexia and disorders of the circulation, progress slowly and insidiously, and are usually marked by a periodical, intermittent type of symptoms, which exhibit a continuous succession of paroxysms and remissions, until they assume at last a

stationary character. Recent attacks, or such as have lasted but a short time and are uncomplicated with organic disease and secondary affections—strabismus, atrophy, &c.—allow a favorable prognosis, and we often notice in such cases not only a speedy improvement after proper treatment, but also a spontaneous *restitutio ad integrum*. In the chronic forms, on the contrary, the prognosis is altogether unfavorable; for, not to speak of the incurability of the originating affection, the paralysis itself, bound to morbid conditions that have become inveterate and intractable, evinces very little inclination to retrograde, and leads most frequently to serious secondary troubles and changes, such as diplopia, vertigo, strabismus, amblyopia ex anopsia and total degeneration of the implicated nerves and muscles.

In congenital paralysis of any ocular muscle, owing to innate central disease, hereditary syphilis, &c., the prognosis is also very unfavorable, for even after the primary, constitutional disorder be no longer in operation and wholly obliterated, the morbid changes in the affected parts will strenuously oppose all efforts to remedy the resulting paralysis.

The treatment must in all cases be directed, first and foremost, against the originating disease—that has produced the paralysis and is maintaining it—and only after the pathogenetic causes have been removed, or their injurious influence reduced, and the paralytic symptoms still prevail, the direct, mechanical and operative methods of treatment are indicated.

In cases of recent origin, topical abstractions of blood, antiphlogistic, emollient, derivative and revulsive remedies may be employed with advantage against the exciting cause still in operation. When they are more advanced, alteratives, such as mercury, especially in the form of inunctions, and iodide of potassium, are apt to aid in the resorption of exudations, even though not of a specific character, and to exert a favorable influence upon the course and termination of the affection. If all these remedies prove of no avail, and the paralysis remains unyielding, the application of electricity, either in the form of Faradization or the galvanic current, is advisable; the latter is by far the more preferable, and proves of decided value in a great number of cases. Always beneficial in paralysis with a rheumatic basis, it produces often a curative action even in cases where the primary, intracranial affection still exists, and is beyond the reach of any improvement. But in or-

der that the greatest possible benefit be obtained, the galvanic current should be applied to the trigeminus, and not directly to the nerves supplying the muscles themselves, as, generally speaking, the best and speediest results are effected by reflex excitation through the fifth pair. The current used for that purpose must be relatively weak, not strong enough to produce muscular contraction, and its proper strength determined in each special case by the sensitiveness of the nerve operated upon, and the irritability of the patient. The excitation should continue only a very short time, from half a minute to one minute, at most—longer and more powerful application being apt to aggravate the original paralysis. In the greater number of cases indicating electrical treatment, the improvement takes place instantaneously (Benedikt), and is chiefly shown by an increased mobility of the eye and a diminution of the field, in which double images arise. When, however, the paralysis has been unaffected by a galvanic treatment of two weeks' duration, it should be desisted from, as no benefit is to be expected from its longer continuance (Benedikt).

In connection with the treatment just indicated, it is further of great importance to exercise and strengthen the paretic muscle, by covering the healthy eye at intervals during the day, and compelling the affected one alone to exert its visual function, especially in the direction of the diseased parts. For the purpose of improving the innervation of the muscle at fault, the eye should be adjusted for near or distant objects in accordance with the correction, that is attempted by the exercise—adduction or abduction—and if necessary, spherical glasses should be used, either to diminish or to increase the refractive power of the eyes.

In paralytic affections of less degree, the systematic treatment with prismatic glasses has been warmly recommended, and some ophthalmic surgeons of note have employed them in even more decided cases of paralysis with consequent strabismus. "Prisms with the base turned in the direction opposite to that of the squint have the power of causing a deviation of rays of light incident on their base, which may thus be used to deflect the rays proceeding from objects looked at, so that they may, in the case of the squinting eye, be made to fall upon a part of the retina congruous to that which receives them in the normal eye." Prisms may, in fact, be used thus to fuse and destroy double images and to

restore binocular vision. But apart from that optical function which has a temporary effect only, and leaves the material cause of the paralytic strabismus still in operation, they perform also a truly gymnastic one, by exercising and strengthening the parietic muscles and exciting them to a more uniform and synergic action. Unfortunately though, the practical results of that method of treatment do not correspond to the expectations which might theoretically be entertained, and the correction of the trouble by prismatic glasses is either not practicable in the majority of cases or aptly prepared for by the preliminary performance of tenotomy.

This operation, first performed by Dieffenbach on the living body, and after a period of apparent oblivion revived and brought to universal recognition by Graefe, takes foremost rank in the treatment of all forms of strabismus—pure and paralytic—and is indicated when all other curative methods have failed, and the affection threatens to cause severe secondary disorders, such as luscitas, amblyopia, &c.

Previous to undertaking an operation for the cure of paralytic strabismus, it is essential to ascertain, 1st, whether there is a sufficient capacity and breadth of fusion; and 2d, whether the paralysis has assumed a stationary character: these are conditions *sine qua non*, and their presence is indispensable to the successful treatment of the affection. The act of fusion of double images is a purely cerebral, not a sensorial function, and therefore does its loss or impairment clearly indicate the existence of an active, intra-cranial disorder, and the central origin of the paralysis (Graefe); although the latitude of fusion may also decrease with advancing years, after the visual power of one eye has been lost for a long time. If double images can be made to coalesce by means of prisms, the breadth of fusion is proved to be normal, the intuitive desire for binocular vision preserved and readily obeyed, and the scope perfect. While, therefore, a total loss of capacity and breadth of fusion will render all curative efforts unavailing, the cure of paralytic strabismus and diplopia will be—*ceteris paribus*—the simpler and easier, the more they are developed.

When the pathogenetic cause is no longer active, the affection has become stationary, the paralysis of the one or the other muscle remains unyielding, or secondary contraction of the antagonist has taken place, tenotomy should be at once performed; and it is obvious, that the extent

of the operation has to be regulated according to the degree of the affection. A few remarks on the leading principles of tenotomy, or, to speak more accurately, of strabotomy, may not be out of place.

Slight strabismic deviations, from 1 to  $1\frac{1}{2}$  line, demand a partial tenotomy only,\* but if they amount to from  $1\frac{1}{2}$  to  $2\frac{1}{2}$  lines, the tendon must be completely divided; and the greater the deviation, the larger must be the hook employed, and the more freely the cellular tissues incised. Operations performed on one eye only, correct deviations amounting to  $2\frac{1}{2}$  lines; if the strabismus exceeds that amount, both eyes must be operated upon. Either a complete tenotomy should be performed in the squinting eye, and a partial one in the other, or the tendon should be completely divided in both eyes—a point to be decided by the amount of strabismus left, after the affected eye has been operated upon. It is a proper rule not to operate on both eyes in one sitting, especially in convergent strabismus—except, perhaps, in cases where the deviation exceeds 5 lines—for if both muscles have been divided at the same time, the accommodative movements directly after the operation cannot be accurately tested, and the only clue to the permanent effect is thus lost. The better and safer plan, and the one adopted by most ophthalmic surgeons, is to operate first on the squinting eye, and then, after the divided muscle has again re-united with the sclerotica, and the degree of the remaining deviation has been ascertained, to perform an operation on the healthy eye, the extent of which will depend upon the amount of strabismus still left. Any excessive effect of the operation can be reduced by a suture, the object of which is to re-advance the tendon, which is closely connected with the conjunctiva and subconjunctival tissue, to approximate more closely the divided ends, and to diminish the retraction of the muscle. The greater or less effect depends upon its position and the amount of conjunctiva embraced in it; it is greatest if inserted in a diagonal direction, and least, answering merely a cosmetic purpose, if inserted above. When the operative effect is too slight, it can be increased by the excision of a semi-lunar portion of the sheath and conjunctiva in the direction of the opposite side. In every operation for strabismus the effect is more variable than constant (Graefe).

Slight strabismic deviations require only the more or less complete division of the

\* We are informed that partial tenotomy has been abandoned by oculists generally.—Ed.

tendinous insertion of the muscle at fault, which loses power by its posterior attachment to the sclerotica, and causes, therefore, a smaller angle of squinting, the more the excursion of the globe is lessened in its path. Greater deviations, on the contrary, necessitate the distribution of the operation over both eyes, or render it, at least, far preferable to the immediate result of one operation only—and indicate the complete section of the affected muscle, together with a less complete division of its associate of the other side. The same operative principles which obtain in the treatment of pure strabismus, are also admissible in paralytic squint with deviations not exceeding 1 to 2 lines; but if the paralysis is more decided, the insertion of the parietic muscle must be *advanced* by means of the suture, or in extreme cases by the “thread-operation,” and at the same time the antagonist divided more or less completely. This method is equally applicable to primary strabismus, with an excessive angle of squinting and greatly impaired mobility in the path of the affected muscle, as to secondary squint, where the mobility in the course of the retracted muscle is nearly lost, and its connection with the eyeball totally suspended. Very rigid inquiry into the behavior of the various muscles, no less after than before the operation, and in near as well as in distant vision, is the indispensable condition of success in all operations. The frequently difficult question, whether parallelism is restored, or whether there exists yet some deviation from it in one or the other direction, must be decided by means of a prism, with its base downwards, and the dynamic latent preponderance must always be measured—these conditions determine the effect of the operation and the further course to be pursued. (If after an operation for convergent strabismus divergent squint develops in the course of time, it is owing to the fact that the dynamic deviation, already existing, has steadily increased, and at last can be no longer suppressed by the latitude of fusion.—Graefe.)

Just as in all other tenotomical or myotomical operations, so also in the operation for strabismus, the orthopædic after-treatment is of the utmost importance, and on the manner in which it is conducted depends to a great extent the permanency of success. The chief agents employed in that period are: stereoscopic exercises, suitably adapted glasses, prisms, and spectacles, by which the patient is compelled to direct the eye—in order to see—exclusively towards the right or the left side, just as the special case may require.

To sum up:—Tenotomy is able to effect in all forms of strabismus, whatsoever, an essentially improved, if not a perfectly normal position of the eyeball; it does further effect, in all cases in which the resulting amblyopia has not yet attained a very marked development, an improvement of projection, accommodation and distinctness of vision. The operation is not contra-indicated by incongruence of the two retinæ—although the disorder in question has to be remedied by a special after-treatment—and if in consequence of extensive corneal opacities, an aberration of the visual axes has already ensued, which prevents the recovery of better vision, it may at least fulfil a cosmetic indication. (Berliner D. Klinik. Report of commission.)

It remains yet to say a few words on mydriasis, paralysis of the accommodation, and their mutual relations.

According to Graefe and other observers, it is more than probable that the iris exerts no direct influence whatever upon the act of accommodation, as the perfect integrity of the latter has been proved in cases of an artificial pupil, traumatic loss and congenital absence of the former; but its auxiliary and indirect influence can hardly be denied, when the facts are taken into consideration, that a considerable impairment of accommodative power becomes manifest by extensive posterior synechiæ—and to some extent also after the performance of iridectomy (Stellwag)—and that in almost all cases of congenital irideremia a deficient development of the ciliary muscle is complicated with it. Simple mydriasis leads not necessarily to a paralysis of the accommodation, since it depends on a variety of causes, which affect the ciliary fibres of the iris only, either temporarily, as in the ephemeral form, or more constantly, as in the spasmodic, in which the dilatation of the pupil is undoubtedly owing to a spastic contraction of the radiating sympathetic fibres overpowering the action of the sphincter. But in the paralytic form, that occurs most frequently, paralysis of the accommodation is almost always present, for the reason that the same pathogenetic cause implicates the sphincter of the pupil and the ciliary muscle, intimately connected and supplied by the same nerve as they are. In cases of pure, uncomplicated paralysis of the ciliary muscle—and sphincter of the pupil—the originating disorder may exceptionally be seated in the cerebrum, but is almost invariably located in the lenticular ganglion or its radix brevis. Paresis of the accommodation and mydriasis

sis, on the contrary, which are combined with and in part symptoms of extensive functional disorders involving several muscles of the eyeball, are either due to morbid processes in the sheaths or trunks of the motor nerves, or oftener yet to affections in the central organs themselves. These primary affections are not always strictly material ones, consisting in marked changes of the organic tissue, but often unaccompanied by any manifest alterations, and then the expression of certain dyscrasias and intoxications only, such as mania a potu, diabetes, uræmia, &c.

Quite singular and characteristic is the paresis of accommodation, which is frequently met with in diphtheria, complicated with paralytic disease of the palatine and pharyngeal muscles. The unknown morbid cause seems to affect the ciliary muscle only, and to leave the circular fibres of the iris wholly intact; for, although one or more of the ocular muscles innervated by the third pair may at the same time be implicated in the diphtheritic paralysis, yet mydriasis is but very seldom observed. (When the two pupils present a different pathological appearance—mydriasis in the one eye being complicated with myosis in the other—the difficult problem, which of them comes nearer the normal condition, is decided by observing which possesses the greater excursive capacity and accommodative power.) The treatment of mydriasis and paralysis of the accommodation must, of course, be directed first and foremost against the pathogenetic cause, whenever such is practicable and promises any success. If the primary affection has been removed, and the mydriasis still exists as an independent disease, due to material, morbid changes in the nerve or muscle, remedies must be employed calculated to incite the sphincter papillæ to vigorous contractions, and for that purpose the direct excitation of the paralyzed parts by tincture of opium, the preparations of the Calabar bean (*phyostigma venenosum*), vapors of ammonia, and electricity is indicated. Forceful and methodically repeated contractions of the orbicular muscle—anti-mydriatic exercises—have been recommended by Graefe. The cure of paralysis of the accommodation requires a combination of remedial agents, general and local, which are apt to impart more vigor and vitality to the whole system as well as to the affected parts. Cautious exercise of the accommodative apparatus by suitably adapted convex glasses—varying as to degree, according to the particular circumstances—cold douches, gene-

rous diet, a hygienic regimen, and the internal use of quinia, ferrum and other tonics, are chiefly capable of restoring the impaired ciliary muscle to its proper functions and of improving the power of accommodation.—(Donders.)

The artificial mydriasis and paresis of accommodation, produced by belladonna, hyoscyamus, stramonium, &c., and their alkaloids, differ from the natural forms only as to cause and duration. If the application of the remedies just mentioned is moderate, mydriasis only ensues, but with their increase in strength and dose, the ciliary muscle, too, becomes paralyzed and the accommodation is temporarily annulled. In spastic contractions of the muscles, which execute the movements of the eyeball and are innervated by the third pair, especially in such as are produced by direct lesions, mydriatics have been employed with signal success; and the singular observation has been made, that the same agents which give rise to a thorough paralysis of the accommodation, if excessively used, restore the accommodative functions, suspended by the spasm, even before they have a chance to effect a dilatation of the pupil. (Graefe.) This antispasmodic effect of the mydriatics explains pretty satisfactorily the favorable influence they exert in the treatment of keratitis, iritis, iridochoroiditis, ulcerative processes, &c., for by reducing the irritation and hyperæsthesia of the sensory ciliary nerves, which usually attend inflammatory conditions of the eye, and by decreasing the *intraocular tension*, they act as truly sedative and antiphlogistic remedies. Ophthalmic practice is indeed vastly indebted to these invaluable remedial agencies, and no less a man than Graefe is authority for the sentence:—Atropia is the staff of ophthalmology.

CASE 1.—*Paralysis of the left Abducens, complicated with Mydriasis, Loss of Accommodation and Partial Anæsthesia of the left Trigemini.*—The facial, trochlear and oculomotor nerves, with the exception of the pupillary branch and the motory fibres of the ciliary muscle, were in a perfectly normal condition. The near point of the healthy eye—Jaeger No. 1—was at five inches, the far point in infinite distance, consequently normal; in the affected eye, on the contrary, the near point was, with the aid of a convex 7, found at six inches, and the far point quite close somewhere between 8 and 9 inches—thus indicating an exceeding impairment of the range of accommodation and a diminished power of vision. (Was this complication solely owing to the

ciliary fibres of the third nerve, which was otherwise nearly intact, being involved, or was it, together with the mydriasis present, more intimately connected with the paralysis of the abducens? For, according to Graefe and other observers, it is highly probable that the abducens takes a more or less decided part in the complex accommodative processes and in the movements of the pupil.) There was no protrusion perceptible in the orbit, but on pressure upon a small, circumscribed spot, the patient exhibited considerable sensitiveness, which might have been occasioned by a gumous tumor. Cerebral symptoms, psychical and hemiplegic disorders were wanting; therefore the origin of the paralytic affection was not to be sought for in the brain itself. The partial, circumscribed anæsthesia on the left side, however, rendered the diagnosis of a purely orbital disease improbable, and induced Graefe to locate the pathogenetic cause in the basilar region of the cranium. The trouble had slowly and gradually developed after a severe cold, and was no doubt owing to a *syphilitic*, cranial process, as a specific ulcer had existed long ago, and the characteristic osteocopic pains had troubled the patient for some time past. Mercurial inunctions and iodide of potassium operated favorably upon the primary disease, and the performance of tenotomy, &c., corrected the convergent strabismus and diplopia, and improved considerably the visual power of the eye.

CASE II.—*Paralysis of the Fifth and Sixth Pair, uncomplicated with Neuro-paralytic Ophthalmia.*—The left abducens and several branches of the left trigemini were completely paralyzed, the temporal and masseter muscles in a state of atrophy, and the bulbous, the eyelids and almost the entire half of the face, including the corresponding half of the nose and tongue, anæsthetic. The cranium was in some parts thickened, in others sunk in, and severe pain in the head, alopecia, intumescence of the glands and a profuse nasal catarrh further complicated the case. This group of symptoms was undoubtedly owing to lues, and the paralytic affection of the eye could only be explained by the existence of a specific, osseous disease in the basilar region of the cranium, which had extended to the origin of the implicated nerves. The diagnosis of cranial periostitis of a specific character, was corroborated by the speedy and favorable effect a rigorous antisyphilitic treatment produced upon the greater number of the morbid phenomena. Graefe thinks that paralysis of the fifth nerve is

usually complicated with neuro-paralytic ophthalmia, and originates most frequently from syphilis and its secondary manifestations. In connection with this case, in which softening of the eyeball was not noticeable, he took occasion to express his dissent from the view held by Donders, that trifacial anæsthesia had the tendency of rendering the globe more soft. He stated that in eight or ten cases which had come under his observation, he had failed to notice that connection, and attributed the fact of the globes becoming softer after section of the fifth nerves, in consequence of a decreased tension, to other causes, far more complicated and not yet cleared up.

CASE III.—*Paralysis of the left Abducens and Oculomotorius, with Secondary Strabismus in the Right Eye.*—The affected eye showed no mobility upwards, inwards and outwards, only the movement downwards was unrestrained on account of the perfect integrity of the trochlearis. The levator palpebræ superioris was impaired, but much less so than the rectus superior; the sphincter of the pupil and the ciliary muscle were also palsied, and in consequence mydriasis and loss of accommodation became apparent. The right eye revealed an excessive strabismic deviation upwards and outwards; although not primarily diseased, and having become affected with squint only on account of the paralytic condition of the other, it had lost, to a great extent, its visual power by being excluded from the common act of vision. Not participating in that, it revealed a secondary deviation whenever the other eye fixed any object; and the loss of correspondence in the direction and movements of the two eyes had gradually led to an affection of the optic, nervous apparatus in the weaker. The paralyzed eye, possessing stronger and distincter sight, performed exclusively the act of vision, and condemned the squinting one to remain—as far as its function of seeing was concerned—in a state of utter passivity, which gave rise to torpor of the retina and to optic anæsthesia. Amblyopia ex anopsia, arising under such circumstances, affords in most cases only a very insignificant, if not a negative ophthalmoscopic sign; whenever atrophy of the optic nerve is found in anopic amblyopia, it results not from exclusion alone, but from a complicated neuritis or other affections of the optic nervous organs. The history and appearance of the case rendered it highly probable that the morbus causans was a peripheral one, and of rheumatic character, yet having existed for a considerable time, and being complicated

with functional disorders, and most likely, too, with material changes in the affected nerves and muscles, the prognosis was considered unfavorable. Local depletions with Heurteloup's artificial leech were made, which gave considerable relief and freed the patient from the severe spontaneous headache and the great pain consequent upon knocking on the head; and to meet other indications mercurial inunctions and iodide of potassium were prescribed.

CASE IV.—*Paralysis of the Oculomotorius, Abducens, Trochlearis, upper branch of Trigemini and Infraorbitalis*, with perfect immobility of the eyeball, paralysis of sensibility, and anæsthesia of the cornea, without the slightest reaction on touch. All these symptoms were one-sided and complete, and on that account the primary cause of the paralysis could probably be a peripheral one only—central palsies of a similar character being of very rare occurrence. In this case the etiology aided, in combination with the symptoms present, in establishing a correct diagnosis and in determining the exact seat of the originating trouble. It had begun suddenly, after exposure and a severe cold, with excessive pain in the orbit, increased by pressure, and later rigidity and gradual protrusion of the eyeball had followed, together with the paralytic disorders in the various nerves implicated. The suddenness of the attack proved at once its rheumatic character, and excluded all direct and immediate connection with syphilis, &c.; it was a clear case of plastic inflammation of the orbital periosteum, with secondary neuritis, which had produced the paralysis. Periostitis of the orbit is owing to a great variety of causes, either of a constitutional or local character, which modify considerably its course and termination. Vehement concussions, direct lesions and also causes not understood, give rise to it, and develope its symptoms sometimes very slowly; arthritis, mercurial cachexia and syphilis play an important part in its production, but it is chiefly scrophulosis that leads to the most torpid and protracted forms and complicates them with caries and necrosis. Among its indirect causes are orbital abscesses and tumors, phlegmonous dacryocystitis, and suppurative meningitis, the most frequent and usually leading to caries of the bones composing the walls of the orbit. The case under consideration being of a purely rheumatic character and of comparatively recent date, admitted at least of a doubtful prognosis—*vergens ad faustam*—and gave hope of yielding to proper curative measures.

Local abstractions of blood, a strict antiphlogistic and derivative treatment, later iodide of potassium, &c., were resorted to, and proved of decided benefit.

CASE V.—*Bilateral Paralysis of the third, fourth, and sixth Pair*, with paralytic ptosis, slight prominence and almost complete immobility of both globes; but perfect integrity of the circular muscular fibres of the two irides, and of the ciliary muscles, and consequently with a normal condition of the pupils and an unimpaired power of accommodation. This singular phenomenon—the perfect integrity of accommodation and pupillar contraction, contrasting with an absolute immobility of the eye (by the thorough paralysis of its entire motor apparatus)—has been repeatedly observed by Graefe, and he looks upon it as a characteristic symptom in such cases as the one under consideration. These observations were used as a striking and successful argument against those who had asserted that the accommodation was owing to the united action of the external muscles on the eyeball, and had denied the chief instrumentality of the ciliary muscle, in performing the accommodative function. The affection, which had suddenly arisen, was probably due to a speedily forming infiltration on the basis cerebri in consequence of periostitis in the dura mater; at first vehement pains had been present, but they had gradually ceased and returned only occasionally with greater intensity. These were all the anamnestic data that could be ascertained respecting the trouble, the patient having formerly enjoyed good health and being utterly unable to mention any cause which might have given rise to it. Etiological momenta, pointing to any morbid tendency, specific disease, &c., were also wanting, as far as the objective examination could disclose them; yet syphilis was suspected as the primary cause, and as more likely to have produced the paralysis than an idiopathic or rheumatic cranial affection. The absence of any diffuse cerebral symptoms, of paralytic disorders in other parts, and of serious complications with the optic and sensory nerves of the eye, proved sufficiently that the original trouble had not extended beyond its first seat, that the fierce, most intense stage of the intracranial disease had passed away, and that the latter's power for mischief had greatly decreased within its narrow, circumscribed limits. The prognosis in such cases depends, apart from the pathological cause, from constitutional or local complications and other less appreciable influences, chiefly on their course and

duration. Rapidly developing bilateral paralysis of the third, fourth and sixth pair admits usually of a favorable prognosis, and as the infiltration giving rise to it disappears, a speedy retrogression of all paralytic symptoms takes place simultaneously. Chronic cases, on the contrary, and such as arise slowly and insidiously, are unexplainable and far more unfavorable; for besides the severe cerebral disorders usually complicating them, the visual power, too, becomes greatly impaired, and amaurosis, more or less complete, supervenes. In the case under consideration an energetic antiphlogistic treatment, mercurial inunctions and iodide of potassium were consecutively employed with signal benefit.

CASE VI.—*Paralysis of the right Oculomotorius of traumatic Nature and long Duration.*—The first stages of the affection had been marked by intervals of complete improvement and an apparent *restitutio ad integrum*; at times very violent headaches had occurred, during which the paralytic symptoms intermitted, to return again after the cessation of the former. For the last two years, however, the paralysis had existed uninterruptedly, although the characteristic headaches still came on periodically and in paroxysms. They were owing to the residua of a probably periosteal affection, which produced continually fresh irritation, and gave rise to typical exacerbations, without any palpable cause becoming apparent. The paralysis itself was now dependent on pathological changes in the involved nerve and on secondary atrophy and fatty degeneration of the muscles supplied by it. The prognosis, under these circumstances, was highly unfavorable, and no benefit could be expected from a medical or operative treatment, even though the primary affection had been wholly removed. There was an interesting phenomenon connected with this paralysis, namely, the very slight ptosis; and Graefe tried to explain it, by pointing to the fact that chronic paralysis of the third nerve was usually attended with very slight ptosis, while in the acute form it developed rapidly and became more marked.

ciety for Medical Improvement, which has a certain precedence. At all events, as extra pages are supplied, articles which have been waiting have not been thrust aside to make room for it.

## AMERICAN MEDICAL ASSOCIATION.

(Continued from page 268.)

WE surrender the chief part of our Editorial space this week to a continuance of the report of the late session of the American Medical Association.

Dr. L. P. Yandell, Jr., of Kentucky, offered the following, which was adopted:—

*Resolved*, That private handbills, addressed to members of the medical profession, or by cards in medical journals, calling the attention of professional brethren to themselves as specialists, be declared in violation of the Code of Ethics of the American Medical Association.

The special order for one o'clock being the report on American Medical Library, Dr. Toner, chairman, read the report.

After some discussion, on motion of Dr. Hibberd, of Indiana, the report was accepted.

Dr. Davis, of Illinois, offered the following resolutions:—

*Resolved*, That the proposition of the Librarian of the Congressional Library be accepted.

*Resolved*, That a committee of one be appointed, residing at Washington, to render the Librarian of Congress such assistance as the interests of the Association may require. Adopted.

Report on Medical Education presented, and, on motion of Dr. Hibberd, of Indiana, it was made the special order for 10 o'clock to-morrow.

Committee on Prize Essays reported:—

The undersigned, appointed Committee on Prize Essays at the session of 1868, respectfully report:—

They have received but two essays—one upon "The Physiological Effects and Therapeutical Uses of Atropia and its Salts"; the other upon "Quinine as a Therapeutic Agent." They agree to present both of these essays to the Association, and to recommend the award of a prize of \$100 to each of them.

S. M. BEMISS, *Chairman*.

C. BEARD, M.D.

JOSEPH T. SCOTT, M.D.

S. A. SMITH.

The Secretary broke the seals, and announced that Dr. S. S. Herrick, of New

## Medical and Surgical Journal.

BOSTON: THURSDAY, MAY 20, 1869.

ONE of the communicated articles of today is matter belonging to the Boston So-

Orleans, was the author of the paper on quinine, and Dr. Roberts Bartholow, of Cincinnati, was the author of that on atropia.

Remarks upon certain points referring to success in the operation of vesico-vaginal fistula, by M. Schuppert, M.D., of New Orleans, La. Referred to Section on Obstetrics.

On motion of Dr. Davis, the Sections were authorized to meet at 3½, P.M., in place of 8.

Communication from Gynæcological Society was read by Permanent Secretary, and, on motion of Dr. Davis, was laid upon the table.

Dr. Booth, of Mississippi, offered the following resolutions:—

*Resolved*, That the proper construction of Art. 4, Sec. 1, Code of Ethics, A. M. A., having been called for, relative to consultation with irregular practitioners who are graduates of regular schools—

*Resolved*, That said Art. 4, Sec. 1, Code of Ethics, A. M. A., excludes all such practitioners from recognition by the regular profession.

On motion, the Convention adjourned until Thursday, at 9, A.M.

*Notes of some of the Debates.*—During the debates on the revision of the plan of the organization, considerable interest was excited by the amendment with reference to a change in the mode of balloting for President, and a discussion arose, participated in by Drs. Ross of Alabama, Davis of Illinois, Woodward, U.S.A., Mussey of Ohio, Dr. L. A. Sayre, of New York, was generally of the opinion that these tinkering of the constitution were inexpedient. He at first moved that the amendment be laid on the table, but subsequently withdrew the motion in favor of Dr. Lindsley, of Tennessee, who also expressed himself in opposition. The question being called by Dr. Sayre, the sense of the Association proved to be largely against the proposed amendment, and it was rejected unanimously.

Another resolution that called for special attention, and was closely debated, was the resolution offered by Dr. J. R. Barnett, of Vicksburg, to which reference has already been made. A sharp discussion ensued—with the speakers, with the exception of Dr. Barnett, solid against it. It was clearly the opinion of the meeting to discountenance all practitioners of special dogmas, and to frown down any professional consultations between them and regular physicians. The debate on the resolution was brought to a close by the approach of the

hour (1, P.M.) previously fixed for consideration of the report of the Committee on a "Library of American Medical Works." The President called the hour, and the matter was dropped. The recognition of Homœopathy by the profession is still an open question; or, rather, it seems to be settled for some time.

The "Report on the Practicability of establishing a Library of American Medical Works," read by Dr. J. M. Toner, of the District of Columbia, and signed by himself as Chairman, Drs. N. S. Davis and D. Francis Condie, elicited a spirited exchange of views. The main interest turned upon the expediency of avoiding the danger to the proposed Library which might result from the books being placed in the new Hall and Library Room of the Association. Upon this subject the report stated that the Medical Society of Washington City had just completed a Hall and Library Room, and would cheerfully assume control of all the works collected by the American Medical Association, and keep them in a condition to be readily consulted. But lest an objection might be raised in the Convention that would defeat the measure almost in its inception, that the Association had not a fire-proof building to keep safely such a collection, the report recommends that the books, when collected, be placed in the library of Congress, with an agent or Librarian of the Association to receive packages and pay all expenses resulting from their deposit.

A copy of the correspondence between Dr. Toner and Mr. A. R. Spofford, the Librarian of Congress, offering to receive the books, is included in the report. The discussion was both full and interesting, ending in a resolution in accordance with the recommendations of the Committee.

THIRD DAY, THURSDAY, MAY 6, 1869.

The committee on President's Address presented the following report:—

We cannot refrain, before entering upon the consideration of the plan recommended by the President, for the improvement of medical education, from gladly expressing our high appreciation of the general tone of this address, of the broad and catholic spirit which pervades it, finding expression in earnest and eloquent words—in brief, we believe the address worthy the perusal of every member of the profession, in that it was worthy the memorable occasion, and is worthy the annals of medicine.

On the other hand, we cannot refrain, with sadness be it said, from acknowledging

the truth of the terrible allegations made against the present condition of medical education, and the little success attending the efforts for improvement in such connection, made during a score of years.

The special recommendation made by the President is in these words:—

"I would advise that we appoint a committee of our wisest and best men to digest a plan for one or more National Medical Schools, and to memorialize Congress in behalf of the enterprise. Let the plan embrace as a basis the features presented by the Cincinnati Convention of Teachers; let these schools or universities confer such distinctions and privileges as will be proportionate to the superiority they demand, and such as will make the attainment of their diploma an object of the ambition of those who engage in the study of medicine; let the choice be open to all aspirants, and the appointment or election of professors so guarded as to secure the very highest talent, the most profound learning with the most fully demonstrated capacity for teaching. Make the salaries of the professors large, and not to depend upon the number of students; and let the Federal Government assume a proper share of the expenses incurred."

Your committee express their hearty approval of this general plan, but suggest that the effort at first should be for the establishment of but a single school, as more feasible, and beside one such institution would be a model which other medical colleges might in time be induced to imitate in extent, duration and thoroughness of teaching, and in rigidity of requirements for the degree of M.D.

We likewise desire to say that when the details of this general plan are thrown into form there should be the amplest security against the places and the power of such a medical college as designed ever falling into the hands of politicians or the protégés of politicians. Medicine is higher than politics, broader than political creeds and party platforms.

In conclusion, your committee reiterate the recommendation of the President as to the appointment of a committee for the special purposes referred to.

Drs. Parvin, Welch, Seely, Toner and Pollock, committee.

Dr. Hibberd moved acceptance, was adopted, and on the proposition of Dr. Davis the committee was ordered to consist of five. The President appointed Dr. W. O. Baldwin, of Alabama; Dr. F. G. Smith, of Pennsylvania; Dr. Dr. D. H. Storer,

of Massachusetts; Dr. E. F. Gaillard, of Kentucky, and Dr. Joseph Jones, of Louisiana.

The President appointed as Delegates to the British Medical Association:—

Dr. N. Pinckney, U. S. N.; R. R. McIlvain, Ohio; J. F. Hibberd, Indiana; B. Lindsey, D. C.; G. C. Blackman, Ohio.

To the Canadian Medical Association:—Dr. Alden March, Albany, N. Y.

To the Committee on Ethics was appointed:—Drs. Sayre, N. Y.; Toner, D. C.; Askew, Delaware; Arnold, Ga.; McCluskey, Alabama.

Dr. Davis read report of meeting of editors, and presented the following from the Association of American Medical Editors:

To the American Medical Association:

I have been instructed to announce to your honorable body, that those members of your Association in attendance on this annual meeting, after proper consultation, have effected a permanent organization, with the title of "The Association of American Medical Editors." The objects of this organization are the cultivation of friendly relations, mutual assistance, community of efforts and views, where possible, in system of receiving foreign exchanges, and sending our own journals abroad; concert of action in support of improvements in the present system of medical education, and of a higher standard of preliminary attainments for those who propose to enter upon the study of medicine; in proposing laws for the proper registration of births, marriages and deaths; in collecting the names of all the regular practitioners in the several States, and in promoting generally the value and efficiency of our periodical medical literature. The association thus formed is to hold its annual sessions on the day preceding the annual meetings of this body, and in the same localities. Dr. Mitchell, of New Orleans, is the permanent Secretary, and Dr. J. B. Lindsley, of Nashville, Tenn., the Assistant Secretary. Congratulating your honorable body on the establishment of another organized power within the ranks of your noble profession, I remain yours, most truly,

N. S. Davis, Editor,  
President of Association of American  
Medical Editors.

Referred to Committee on Publications.

The Secretary presented a paper from Dr. Walsh, of Georgia, referring to the action of the Georgia Medical Society in his case. Referred to the Committee on Ethics.

Dr. Parvin read report of Dr. J. C. Reeves, on medical education, which had been made the special order for 10 o'clock, A. M.

Adopted and referred to the Committee on Publications.

The Committee on Nominations—Dr. J. J. Woodward, U. S. N., President, reported the following names:—

*For President*—Geo. Mendenhall, Ohio.

*For Vice Presidents*—Warren Stone, Louisiana; Lewis A. Sayre, New York; F. Gurney Smith, Pennsylvania; John S. Moore, Missouri.

*For Assistant Secretary*—Wm. Lee, District of Columbia.

*For Treasurer*—Casper Wistar, Pennsylvania.

*For Librarian*—Robert Reyburn, District of Columbia.

*Committee of Arrangements*—Thomas Antisell, chairman, Robert Reyburn, C. M. Ford, L. W. Ritchie, W. J. C. Duhamel, D. R. Hayner, C. F. Nally.

*Committee of Publication*—V. Gurney Smith, Pa., Chairman; W. B. Atkinson, Pa.; A. J. Semmes, Ga.; Robert Reyburn, D. C.; Caspar Wistar, Pa.; H. F. Askew, Del.; Wm. Maybury, Pa.

*Committee on Medical Literature*—J. J. Woodward, U. S. A., Chairman; W. H. Anderson, Ala.; Theophilus Parvin, Ind.; Hosmer A. Johnson, Ill.; C. W. Parsons, R. I.

*Committee on Prize Essays*—Grafton Tyler, D. C., Chairman; N. L. Lincoln, D. C.; N. R. Smith, Md.; G. W. Miltenberger, Md.; W. R. Dunbar, Md.

*Committee on Epidemics*—Add the following to fill vacancies: J. K. Bartlett, Wis.; J. B. Jackson, Ky.

*Committee on Education*—T. G. Richards, La., Chairman; E. W. Jenks, Mich.; E. S. Gaillard, Ky.; W. M. McPheeters, Mo.

Time for meeting, in Washington, first Tuesday in May, 1870.

J. J. WOODWARD, U. S. A.

Chairman.

The report was unanimously adopted.

Dr. Herrick, Louisiana, offered amendment to amendment on the duties of physicians to each other and the profession at large.

ART. 1. DUTIES FOR THE SUPPORT OF PROFESSIONAL CHARACTER—PROPOSED AMENDMENT—ADDITIONAL SECTION.

SEC. 5. The spirit of trade and of gain from merchandise should by all means be dissociated from the practice of a liberal profession, and it is important that practitioners should not allow their pecuniary interests to compromise their duties to their patients. Therefore, in cities and other communities where the services of compe-

tent apothecaries can conveniently be obtained, physicians should resign to them the whole business and profits of dispensing medicines.

Laid over to next yearly session.

Dr. Davis offered a report on various propositions and communications from medical societies, which were adopted and referred to the Committee on Publications.

Dr. Davis offered the following:

*Resolved*, That a special committee of three be appointed by the President to present copies of the resolutions adopted before the several State medical societies at as early a period as possible. Adopted.

Dr. Chaille, of Louisiana, chairman of committee, presented a report on medical nomenclature, which was received and adopted, and referred to Committee on Publications.

[To be continued.]

ANSWER TO QUERY ADDRESSED TO THIS JOURNAL BY THE LONDON MEDICAL TIMES AND GAZETTE.—*Official Tincture of Iodine and Aconite Root as applied to the Gum for Periodontitis*.—The *Dental Cosmos* publishes a letter from Prof. Abbott, of New York, in which he states the dose thus:—"In each application of the mixture there are used from two to three drops of it—making from a drop to a drop and a half of the aconite." Prof. Abbott is more than ever gratified with the apparent results of the remedy. He enjoins one precaution in its use—the fluids of the mouth, he says, should be kept from it until the alcohol is sufficiently evaporated to prevent its being washed from the part to which it is applied. This requires about one minute.

ARSENIC AS A CAUSE OF HERPES.—Mr. Hutchinson, in the *London Medical Times and Gazette*, some time since, reported certain cases of herpes zoster which he thought might have been produced by the taking of arsenic prescribed for other skin diseases. In the number for April 17th he gives eight more similar cases. He also mentions two cases of other forms of herpes arising during the taking of courses of arsenic.

VIENNA *versus* CLEANLINESS.—A correspondent of the same journal gives a graphic but not flattering description of Vienna in the matter of cleanliness. He says the

supply of water on a toilet table amounts, at the outside, to a quart. A bath in a private house is a "curiosity." And the water closets must be a curiosity to Americans and English. These contrivances have no water supply *but the stops*. Surpassingly beautiful as Vienna is, the writer says, it has one great fault—it requires one to hold the nose too often. Typhoid is rife; and so is phthisis—called there *morbus communis pulmonum*, *morbus Viennensis pulmonum*, *morbus Viennensis*, names showing what a scourge consumption is in Vienna. No wonder, we add, that the great authorities on cutaneous diseases hail from that city!

EXTRACT from a letter from an American in Vienna:—

I don't think that people at home quite appreciate the fact that here in Vienna the men from "Little Boston" stand at the head of the medical university for diligence and application. This is no empty boast, for if a man sails under Boston colors much more seems to be expected of him. The Americans are altogether the hardest workers here, and young men learn only by experience to husband their strength.

"SUITS FOR MAL-PRACTICE."—*Mr. Editor*:—Two suits for mal-practice against members of the Massachusetts Medical Society, have, the past week, been brought to a successful termination. The first was brought against one of the older members of the Norfolk District, for alleged mal-treatment of a broken thigh. The plaintiff claimed \$10,000 for a shortening of 2½ inches. It was proved to be shortened only 1¼ inches; that this amount of shortening was not unusual; and that the treatment had been good. The trial consumed three days. The jury returned a prompt verdict for the defendant.

The second suit was brought against a suburban physician of age and repute, for alleged deformity of the little finger after a dislocation of the elbow, fracture of the radius, and lacerated wound over the 5th metacarpo-phalangeal articulation. Damages laid at \$5,000. The plaintiff's lawyer threw up the case; and the judge dismissed the action.

Having passed through ourselves the pleasant experience of a suit for mal-practice, we can the more heartily sympathize

with the defendants, both of whom are most deserving members of the profession. Had the verdict been for the plaintiffs, the practice of surgery would have been too hazardous for comfort in this State. D. W. C.

NORFOLK DISTRICT MEDICAL SOCIETY.—At the annual meeting, May 12th, 1869—the largest ever held by the Society—the following officers were unanimously elected for the coming year:—Dr. Benjamin E. Cotting, of Roxbury, *President*; Dr. Christopher C. Holmes, of Milton, *Vice President*; Dr. Edward Jarvis, of Dorchester, *Secretary*; Dr. Eben P. Burgess, of Dedham, *Treasurer*; Dr. D. S. Fogg, of South Dedham, *Librarian*.

*Councillors*.—Dr. G. J. Arnold, of Roxbury, Dr. B. E. Cotting, of Roxbury, Dr. B. Cushing, of Dorchester, Dr. G. Faulkner, of Jamaica Plain, Dr. W. C. B. Fifield, of Harrison Square, Dr. J. G. S. Hitchcock, of Canton, Dr. E. Jarvis, of Dorchester, Dr. A. LeB. Monroe, of Medway.

*Censors*, Dr. J. S. Green, of Dorchester, Dr. J. Seaverns, of Roxbury, Dr. C. C. Tower, of So. Weymouth, Dr. C. E. Stedman, of Dorchester.

*Commissioner of Trials*, Dr. E. Stone, Walpole.

*Committee of Supervision*, Dr. S. E. Stone, of Walpole, Dr. W. S. Everett, Hyde Park.

O'REILLY PRIZE.—We are informed that Dr. Robert T. Edes, now residing at Mt. Pleasant, Southern District, recently received the New York O'Reilly Prize of six hundred dollars for a dissertation on the Physiology and Pathology of the Sympathetic Nerve. Dr. Edes, it will be recollected, took one of the three prizes conferred last year in this State, on dissertations on "The Part performed by Nature and Time in the Cure of Diseases." We have written and placed on file a review of these last mentioned papers, which has been crowded out for some time.

We learn through the *Union Médicale* that the *International Conference with reference to the Wounded in War*, held a short session the 24th of April. A report was made describing disinterested actions which have been performed in behalf of the wounded. M. Langenbeck proposed that in time of war neutral governments be invited to place a certain number of military surgeons at the disposal of the belligerents.

## Medical Miscellany.

A "NUT" CRACKED. *Mr. Editor*.—As tumors are acknowledged to have a growth irrespective of that of the body, so they often have their limits of dimension, their cessation of growth, their degeneration or waste, and finally—no very infrequent occurrence—their spontaneous absorption and disappearance. How fortunate it was not necessary to "ligate" that artery! It might have hurt it. SCURBAN.

THE BILL FOR REGULATING THE PREPARATION OF MEDICAL PRESCRIPTIONS.—The following is the text of the act introduced by Mr. Carpenter, of the New York Assembly, and now awaiting the Governor's signature, regulating the preparation of medical prescriptions:—

SECTION 1. No person employed, or in attendance at any drug store or apothecary shop shall prepare a medical prescription unless he has served two years' apprenticeship in a drug store, or is a graduate of a medical college, or a college of pharmacy, except under the direct supervision of some person possessing some one of the before-mentioned qualifications; nor shall any one having permanent charge as proprietor, or otherwise in any store at which drugs are sold by retail, or at which medical prescriptions are put up for sale or use, permit the putting up or preparation thereof therein by any person unless such person has served two years as apprentice in a retail drug store, or is a graduate of a medical college, or a college of pharmacy.

SEC. 2. Any person violating the provisions of this act shall be deemed guilty of a misdemeanor, and shall be punishable by a fine not exceeding \$100, or by imprisonment, not to exceed six months, in the county jail; and in case of death ensuing from such violations, the person offending shall be deemed guilty of a felony, and be punished by a fine not less than \$1000, nor more than \$5000, or by imprisonment in the State Prison for a term of not less than two years, nor more than four years, or by both fine and imprisonment, in the discretion of the court.

SEC. 3. This act shall take effect immediately.

WE have received from Dr. C. A. Walker, Superintendent of the Boston Hospital for the Insane, a copy of the Library Catalogue of that institution. The Preface states that "this library was founded in the year 1861, and has grown chiefly by purchase to its present size. Alderman Charles F. Dana made a donation of about forty volumes in 1865, and it is indebted to Ex-Alderman W. W. Chapp for as many more the present year. The Boston Public Library last year furnished a large number of second hand volumes and illustrated papers, which were of great service for unrestricted use in the wards. It is hoped further contributions may be received of entertaining literature, as well as of standard books for the library. Pictures of any kind suitable for the decoration of hospital wards will also be thankfully acknowledged." Dr. Walker adds, that "what is of no value to others may be of great use to us."

APPOINTMENT.—Dr. T. W. Fisher, late Assistant Superintendent at the Boston Lunatic Hospital, has resigned to enter upon practice in this city. Dr. Geo. H. M. Rowe has been appointed in his place.

TREATMENT OF RUPTURE OF LIGAMENTUM PATELLE AND OF TRANSVERSE FRACTURE OF PATELLA.—M. Sistach is of opinion that position and immobility for a sufficient length of time are quite sufficient to effect a good cure, without any use of the compressive bandages and apparatus so generally used, which are liable to do harm rather than good, preventing the nutrition of the limb, and specially the formation of the new material which is to unite the divided ends of the tendon, causing atrophy of the limb and local seurv. —*Gaz. Méd. de Paris*.

WARM COD LIVER OIL.—Dr. Betz finds warm cod liver oil often tolerated when the oil cold cannot be borne.—*Memorabilien*.

## MEDICAL DIARY OF THE WEEK.

MONDAY, 9, A.M., Massachusetts General Hospital, Med. Clinic. 9, A.M., City Hospital, Ophthalmic Clinic.

### A CASE OF HERPES ZOSTER OPHTHALMICUS, IN A PATIENT 80 YEARS OF AGE, CAUSING FATAL PROSTRATION; WITH REMARKS.

By B. JOY JEFFRIES, A.M., M.D., Ophthalmic Surgeon  
Mass. Char. Eye and Ear Infirmary, Boston, &c. &c.

A. B., an active and healthy old lady nearly 80 years of age, was attacked December 20, 1867, by a violent neuralgic pain in and about the left eye, running over the forehead and on to the side of the nose. Three days later her physician was called, who regarded it as hemicrania, and prescribed aconite over the frontal nerve. This application did not afford relief. There were occasional remissions, but no real intermissions of the pain as in true hemicrania. The temporal artery was so enlarged at this time as to form a tumor an inch in length under the skin upon the temple, and this in so marked a degree as to give rise to the idea of aneurism. The ocular conjunctiva was excessively inflamed, and an ophthalmic surgeon in consequence called in consultation, who found ulcer of the cornea but no iritis, and prescribed solution of atropine, precautionary. Subcutaneous injection of morphine was also used three times. Eruption on the skin was not noticed till the 25th, five days after commencement of pain, when "excoriations" were seen, covered by thick crusts upon the forehead, side of nose and upper lid, not beyond the median line, which were thought to be due to the application of aconite. Emollient applications were used over the parts affected, and the injection of morphine subcutaneously into the arm was the only other special treatment, with the exception of quinine. (The above brief account is given me by the attending physician.)

I first saw the patient January 3d, two weeks after the commencement of the disease, which I recognized at once as a typical case of *herpes zoster*, affecting the cutaneous and mucous distribution of the ophthalmic division of the fifth or trigeminal nerve—namely, the forehead, upper lid, eye

and side of nose.\* There was swelling and hardening over the artery on the temple, and bunches under the skin; thick, deep-seated crusts scattered over the parts enumerated, where the skin looked unhealthy and had a peculiar pink tinge, exactly limited as the crusts, by the median line on the nose, forehead and scalp. One large crust occupied the edge of the orbit over the exit of frontal nerve. Crusts and scabs were expelled from inside of nose on that side, showing the mucous membrane to be implicated; also occasional slight nasal hemorrhage. The lower lid and cheek were not affected, the disease being accurately limited to the distribution of the ophthalmic nerve. The upper lid was considerably swollen and the conjunctiva inflamed and secreting a muco-purulent discharge, the cornea hazy, and vision reduced to counting figures at two feet; it could not be more definitely determined; considerable photophobia. The iris did not, so far as could be seen through the cornea, seem implicated. The pupil was dilated. Tension of the eyeball not ascertained, from refusal of patient. The general tone and vigor of the patient was good, appetite considerable but capricious; the skin not dryer than would be found in such advanced age; the tongue moist and but slightly coated; the pulse large, full, and 100 to 120; urine high colored, but not very scanty; patient drank considerable; the bowels had acted naturally or by enema. But that which was, so to speak, the essential element of the disease, was the truly fearful pain in the parts affected, of a darting, lancinating and stinging character, with occasional remissions. The skin was tender to pressure, and yet

\* This case is quoted, p. 78, in Dr. H. F. Damon's little book on *Necrosis of the Skin*, thus:—

"Dr. Williams, of Boston, has observed a case of inflammation of the eye from *zoster frontalis*. The neuralgia was of an intense and persistent character. There was no eruption on the integument of the nose supplied by the nasal branch of the ophthalmic nerve."

As will be seen from my report, this statement is incorrect. Moreover, after reading the case at the Newport meeting, 1858, of the American Ophthalmological Society, the President, Dr. Williams, of Boston, stated that he had not recognized the case as one of *herpes zoster ophthalmicus* during the few times he saw it, the disease not having developed itself sufficiently.

not sensitive. During the next three weeks—making six in all—the disease ran its course, the pain ceasing January 24th. The patient kept her strength and some degree of appetite for the first four weeks, but gradually broke down under her suffering. The pulse kept up to at least 90, hard and full. By the time the pain ceased the patient was very much enfeebled and emaciated, and I then for the first time felt fearful she might not rally. She gradually faded away, and died on February 1st, the forty-fourth day from the commencement of the neuralgic pain, without any symptom of other trouble, and retaining her mind to the last. The eyelid had recovered its normal appearance, as also the side of the nose. The conjunctiva remained somewhat injected and the cornea hazy, *probably* also loss of sensation in it. The lid could be voluntarily raised, and secretion had stopped. The crusts on the forehead and scalp, where the pain was the last to leave, remained, and the ulceration was deep and considerable. These crusts were still present post mortem. No examination was made.

As to treatment, I was not able, while in attendance on the case, to follow out anything thoroughly. The patient was extremely self-willed and averse to doing anything that could not be promised as a miracle to relieve her suffering, which was so acute as to well excuse her fear of medicine, since she imagined every thing done but increased the pain. Opium dulled the pain but little, and acted badly on the digestive system and brain. Quinine was taken, six grs. a day for a few days, and I think with some benefit, enough at least for me to use it again another time. The patient would take but little stimulant, which, however, did good, especially toward the end of the disease. The last ten days she refused almost all nourishment. Excitement and mental irritation rendered the paroxysms worse. From the absence of general febrile symptoms I thought possibly digitalis might control the excessive action of the heart, and thereby mitigate the pain by less force in the arteries. Ten drops of the tincture once was all the patient would take. I was not sure, but thought this amount had some quieting effect, and should be led to employ an arterial sedative a second time. After pretty free action of cathartic medicine once or twice the pulse became fuller and slower (75 to 80), but went up again within twenty-four hours. When the disease had run its course then the pulse was feeble, small and not very quick, with great prostration. The thought of section of the fron-

tal nerve the patient would not have entertained for a moment, and it was not proposed, as it would not have relieved the pain in the eye and side of the nose. It might have been in place after the pain had retreated to the forehead and scalp.

In looking over the authorities I find that several—Cazenave, Erasmus Wilson, Hardy, Fuchs, Bärensprung, Neligan and Tilbury Fox—speak specially of ulceration and gangrene possibly occurring, particularly in old people, from herpes zoster. Fuchs alone says:—"It may be fatal. This result has been but seldom observed. Fr. Hoffman had two fatal cases from gangrene. It may also occur from metastasis, or ulceration and hectic fever."

I do not find it anywhere suggested that death might occur by exhaustion from the pain in the aged. That this was the cause in the case I have related there is in my mind no doubt, and I have the concurrent testimony of Drs. S. Morrill and Charles G. Putnam that no other symptom of disease could be found before death, after the pain had ceased and the disease run its course.

Cases of herpes zoster, or shingles, on the trunk are so often seen and so well understood that I need not stop here to give any description of the disease in general. But as I find that it is not understood, or perhaps believed, that this is a complaint which may occur from the crown of the head to the feet, over the course of distribution of the cutaneous nerves, I will here quote from Prof. Hebra, with whom the recent French and English authorities agree. He says:—"Under herpes zoster I include all those skin affections which present the character of herpes, and in which the part of the surface occupied by the groups of vesicles corresponds to the distribution of certain cutaneous nerves, and which, lastly (whether occurring on the head, trunk or limbs), are confined to one-half the body. It is only in rare and exceptional instances that *herpes zoster* attacks both sides simultaneously." "The localization of this disease was formerly much more strictly limited, the only cases which received the name of *herpes zoster* being those in which the eruption is seated on the trunk of the body (and chiefly on the chest), and is confined to one half of it. Further observation, however, has shown that, besides the chest, any part of the trunk or limbs, and even the neck, face or head, may present a similar efflorescence, affecting one side only, and that the changes through which the un-  
vesicles pass, and the whole course of the affection, are in these cases exactly

same as in the disease which occupies the trunk, and has always been regarded as the typical form of zoster."

In support of these views I give a table which I have compiled from the annual reports of the Vienna General Hospital for the years 1857 to 1866, inclusive, showing the number of cases and the regions of the body affected with herpes zoster.

CASES OF HERPES ZOSTER ON DIFFERENT REGIONS OF THE BODY, OCCURRING IN THE SKIN DEPARTMENT OF THE VIENNA GENERAL HOSPITAL, 1857 TO 1866; TEN YEARS.

HERPES ZOSTER.	1857	1858	1859	1860	1861	1862	1863	1864	1865	1866	Total.
Capitis			1	1		2	2	2	2	1	13
Facialis						2					2
Collaris	2						1	1			3
Nuchæ	1					2	1	1			5
Brachialis	2	3		2		2	1	2	2	1	14
Pectoralis	2	2	2	6	1	6	8	6	3	4	48
Abdominalis	1	1				2	2	2			6
Progenitalis							1				1
Petneumæ					2						2
Femorals	2			1	1		1	2	5	1	13
Total in the year.	13	9	3	10	4	12	16	14	14	7	102

Trousseau (*Clinique Médicale*) says:—

"One of the most characteristic phenomena of herpes, at least with old people, I have found to be the persistence of the pain after the disappearance of the eruption. This pain, in the same degree of severity and causing intolerable suffering to the patient, often persists not only for several months, whilst the cicatrices left after the formation of the bullæ are still apparent on the skin, but may even last a number of years.

"I have known an old lady who, at 70, had shingles, and who for fourteen years afterward still suffered the most terrible pain, especially at night. Now I have under treatment a lady of sixty, who for five years has been terribly tormented by the

pains of herpes. I have noticed several times a singular phenomenon:—the simple contact of the clothing often provokes the most unspeakable torture, and yet the skin has superficially a kind of insensibility, which often lasts long after the pains have ceased.

"If the prognosis of zona is not grave in that the patient's life is not hazarded, it is grave in that, with old people at least, its sequela may be intolerable suffering, to the despair of the patient and physician."

This is also the experience of many other observers. The subjects of this clinical lecture were two or three patients with herpes zoster then in the Hôtel Dieu, under Prof. Trousseau's care.

With regard to distribution, Prof. Hirsch says that herpes is wide spread over the earth's surface, among all races of men. He quotes Pruner as having seen it very frequently among the negroes in Egypt; on the other hand, Pollock noticed very few herpetic forms in Persia, and Thompson never saw or heard of a case of herpes zoster among the natives of New Zealand. In regard to its relative frequency upon the two sides of the body writers differ, but in putting together a large number of cases we find that it occurs about as often on one side as the other.

Prof. Christian A. Voigt has most minutely dissected and studied the ramifications and distribution in the skin of the separate cerebro-spinal nerves, and published his researches in the *Memoirs of the Imperial Academy of Vienna*, 1864. Prof. Hebra says:—"On the head, neck and limbs, the tracts of nervous supply pointed out by Voigt agree perfectly with the results of observation in cases of zoster. On the trunk, however, the correspondence seems at first sight to fail. For the dorsal and lumbar nerves are distributed to the skin by three separate sets of branches (posterior, lateral and anterior), which form as many 'tracts of nervous supply' running vertically on either side of the body. In reality, however, each of the dorsal and lumbar nerves takes a separate course forward from the spine to the front of the trunk, and the position of the vesicles of zoster accords perfectly with the distribution of these nerves."

Voigt, from his dissections, followed since 1851, deduces—

1st. Every sensitive nerve-bundle supplies with its peripheral termination a definite larger or smaller district of the skin of the human body, and these districts belong to a definite and constant number of

bundles. The mosaic of position and arrangement of these larger or smaller portions of skin and the peripheric terminal distribution of the sensitive nerves in them is, therefore, not arbitrary or accidental, but positively determined.

2d. This definite mosaic in the arrangement, position and ramification of the peripheric termination of the nerves very probably corresponds to a definite arrangement and position of the origin of the nerves in the nervous centres, brain and spinal cord.

3d. Anomalies occur only in the direction and course of the nerve from the centre to the periphery. Just as in the telegraph it makes no difference whether the connection between two stations is longer or shorter or doubled on itself, so the cutaneous nerves, when running irregularly, even doubling on themselves, yet reach a determined portion of the skin, and there first ramify.

4th. The number of nerve fibres held in any bundle receiving a special name is not always the same, for the fibres, in their course from centre to periphery, change company, join often neighboring nerve branches to again leave them, till, finally, they ramify on their determined portion of the skin.

Amongst various anomalies which Prof. Voigt has found, and from which the above deductions are made, are, in reference to the nerves implicated in our case, the following:—

The *lachrymalis* may be thicker than ordinary, twigs of the *supraorbitalis* running with it in its sheath. As a rule, the *lachrymal* supplies, in its final distribution, only a small part of the upper eyelid above the outer angle, and about six lines outward. I have found bases where a twig of the *lachrymalis* supplied one-half of the skin of the upper lid. Here commenced the twigs of the *supraorbitalis*, which generally emerges from the orbital foramen, but in this case ran down to the upper lid and joined the bundles of the *lachrymalis*; instead, therefore, of running along the upper wall, ran by the external upper angle of the orbit.

"The *infratrochlearis* becomes thicker by uniting with it twigs of the *ethmoidalis* which reaches the skin of the end of the nose between the bone and the *cartilago-triangularis*. The terminal twig of the *ethmoidalis* here runs, instead of *inside*, above the ethmoidal cells and along the anterior wall of the nasal cavity, *outside*, joining with the *infratrochlearis* to the skin of the ridge of the nose, and so to the end where it ramifies."

For the general distribution of the ophthalmic nerve I would refer to the special anatomies. Mr. Hutchinson has given it very perfectly and succinctly in his paper in the *Ophthalmic Hospital Reports*. I quote the above from Prof. Voigt, as the anomalies he found in dissection may possibly explain cases which might occur of herpes zoster ophthalmicus not apparently following strictly the usual distribution of the trigeminal.

The part concerned in our case is what Voigt calls the "anterior district of ramification of the head and face," beginning on the squama of the occipital bone, and running over to the chin. In this ramify the anterior subdivisions of the first, second and third branches of the trigeminus. Draw now a horizontal line, about six lines long, from the external angle of the eye to the "lateral border line," and a line from the internal angle directly to the end of the nose near the anterior part of the nasal opening, and these two lines, with the commissure of the eye, will separate the district of ramification of the first from the second trigeminal branch. In this district terminate the *supraorbitalis*, *frontalis*, *supraet infratrochlearis*, *lachrymalis*, and the end of the *ethmoidalis*, on the point of the nose.

"The ramifications of the *supraorbital* do not, as generally given, end on the crown, but run on further and reach the squama of the occipital bone."

This last fact explains the portraits of the disease given by Drs. Boeck and Danielsén, and Prof. Hebra.

(To be continued.)

## ON THE USE OF THE CHLORIDE OF GOLD IN MICROSCOPY.

By THOMAS DWIGHT, Jr., M.D.

PERHAPS no re-agent has of late years played so important a part in microscopy as the chloride of gold. By means of it Conheim first demonstrated the terminations of the nerves in the cornea; and since it has been very generally used, particularly in investigations of the nerves. Its application is very difficult, and it is only after a long series of experiments and failures that proficiency is obtained.

Having had considerable experience with this re-agent in the laboratory of Professor Stricker, in Vienna, and having obtained some very satisfactory results, I hope that a few words on its application may not be out of place. The chloride should be dissolved in distilled water, and the solution

should never be stronger than the half of one per cent. The object to be examined should be as fresh as possible, and should remain in the fluid from three minutes to perhaps an hour, according to its affinity for the re-agent, during which time it assumes a pale straw color. If the piece be small enough to be readily acted upon, ten or fifteen minutes is almost always sufficient. It is then laid in distilled water, to which just enough acetic acid has been added to give it the faintest possible reaction. In two or three days it will have become purple, verging sometimes on blue, sometimes on red; the latter is the least favorable. The preparation is now enclosed in glycerine, and improves for several days as the color becomes deeper and as the finest fibres are the last to be affected. If the experiment has succeeded, for it sometimes unaccountably fails, the picture presented is one of the most beautiful and instructive that can be imagined. The nerves, muscular fibres and fibrous tissue appear black on the purple background. Epithelial cells are also colored, but not so well as by nitrate of silver.

Although the color makes fibres visible which are so fine that they can be seen by no other method, it does not determine their character. To prove beyond all doubt that a minute fibre is a nerve, we must be able to follow it to a larger branch. On a very successful preparation of the cornea of a frog, I observed nerve fibres of such minuteness that with a magnifying power of nearly two thousand diameters it was impossible to follow them to their terminations. I particularly endeavored to verify the connection, asserted by Kühne but not generally accepted, between the nerves and the corneal corpuscles. With every advantage, such a connection is very difficult to prove. I often thought I had found one; but, when examined by a higher power, and placed in different lights, it proved to be only apparent, except in a single instance, and then it was not certain that the fibre in question was a nerve. I mention these facts as proofs of the value of the method, for it is no paradox to say that the better the preparation the more difficult it is to obtain results. As the magnifying power is increased, elements come into view, which, by inferior methods, are never seen; and spaces are discovered between bodies supposed to be in connection. The use of the chloride of gold, however, is not yet thoroughly understood, and offers a large field for original investigation.

[The preceding article was written at the

suggestion of Prof. Stricker, of Vienna, by whom it has been examined and fully approved.—Ed.]

# TYPHOID FEVER. PERFORATION OF THE SMALL INTESTINES AND CONSEQUENT PERITONITIS. DEATH.

Read before the Boston Society for Medical Observation, January 18th, 1869, by A. L. HASKINS, M.D.

P. C., aged 36 years, laborer, born in Ireland, and residing at 88 Cove St., came under my care Sept. 6th, 1868. Patient states that he has always enjoyed good health, but for the past seven days has not felt so well as usual. Has suffered from constant headache, occasional sharp pains in back and limbs, inability to sleep and anorexia. Has been much disturbed by tinnitus aurium, and his hearing has been remarkably impaired; has also had several attacks of vertigo, and has complained of a sense of weakness, at times so much that he could hardly stand. Six days after the commencement of his illness he had slight epistaxis, and two or three quite severe chills, followed by fever. He was now for the first time forced to take his bed.

On the seventh day of his illness I saw the patient for the first time, and the following is the report of his condition then. He was in bed, bathed in perspiration, skin quite hot, countenance flushed, intelligence good. Has headache, and pain in nearly every part of body. Has some cough, with slight expectoration. Is troubled with a ringing sensation in ears, and is quite deaf. Feels very weak, has no appetite, and cannot sleep. Has much thirst. Bowels regular. Pulse 100, regular, not strong. Tongue red at tip; the remainder covered with a thin, white coat, through which the papillæ appear quite prominently. Respirations 22. The chest and upper part of the abdomen are studded with numerous rose spots. An examination of the chest discovered frequent sibilant and sonorous râles throughout both lungs. The sounds of the heart were normal. The liver of usual size, but the spleen was found considerably enlarged.

The patient, who was in a small, ill-ventilated room, was placed in the largest room at command. He was put upon a diet of milk and beef-tea. To insure sleep, a Dover's powder was ordered at bedtime.

*Eighth day.*—Had a comfortable night. Perspires freely. Skin quite hot. Tongue has some coat. Has but little desire for food. Cough and expectoration increased. Upon

examination of the lungs, numerous mucous and sonorous râles were heard, especially at the bases of these organs. The urine was found loaded with urates. There was also a trace of albumen discovered. Half a drachm each of the syrup of squills and nitric ether was ordered to be given every four hours, and the Dover's powder to be repeated at bedtime.

*Ninth day.*—Did not sleep well last night. Was in much fever. Skin is now quite hot, and patient perspires freely. Coughs much. Feels very restless and weak. Has no pain anywhere. One dejection this morning. Passes urine freely. Pulse 110. Tongue coated and dry. Respirations 26. Pulmonary symptoms as yesterday. Spleen more enlarged. Chest and abdomen still studded with rose spots. Slight tympanites of abdomen, but no tenderness. Patient is to have one grain of quinine four times daily, and is to take two ten-grain Dover's powders at night, if necessary.

*Tenth day.*—Went to sleep last night after the second powder. Cough somewhat diminished. One natural dejection yesterday. In considerable fever last night.

*Eleventh day.*—Rested well. Cough still considerable. Has some headache and slight nausea.

*Fourteenth day.*—Symptoms have continued much the same for the past three days. Is unable to sleep at night without the Dover's powder. Has an exacerbation of fever every night. Cough now very slight. Has some headache and considerable thirst. Bowels regular, and dejections natural. A few rose spots still visible. No delirium. No abdominal pain or tenderness. Perspires freely. Pulse 112, regular and stronger. Tongue has lost much of its coating, but is quite dry. Respirations 20. May omit the squills. To take one half a drachm each of nitric ether and the solution of acetate of ammonia every four hours.

*Seventeenth day.*—Is much improved. No cough. Sleeps well. Appetite better. Pulse 100, regular and quite strong. Tongue moist, and but slightly coated. Rose spots have entirely disappeared. Bowels regular. Spleen still very large. Omit the Dover's powder.

*Twentieth day.*—With the exception of weakness, feels quite well. Pulse 100. Tongue clean. Skin moist. Urine normal. Omit the fever mixture.

*Twenty-third day.*—Is gaining strength. Functions all quite normal. Febrile symptoms have nearly disappeared. May have a small piece of beef-steak.

*Twenty-seventh day.*—Some fever last night. Spleen still much enlarged.

*Thirtieth day.*—Sat up for the first time to-day. Omit quinine.

*Thirty-fourth day.*—Is up and dressed.

*Fortieth day.*—Says that he feels as well as ever. Pulse 80. Tongue clean. Bowels natural. Appetite good.

*Forty-sixth day.*—Has been out to-day.

*Fifty-third day.*—Was seized last night with pain in the right hip. The pain seemed to originate at a point midway between the trochanter major of the femur and the tuberosity of the ischium, and extended downwards to the popliteal space. The pain was of a darting character, and was increased when pressure was exerted upon the course of the sciatic nerve. Patient has considerable fever. Pulse 100. Tongue normal. Hot fomentations were applied along the seat of pain, and one grain of opium was ordered to be given three or four times daily, according to the pain. Patient has been about during the past week, but not at work, although he felt quite able. Asserts that he has been cautious in the use of food, and has committed no excesses of any kind.

*Fifty-fourth day.*—Pain much relieved. Some fever. No appetite. Pulse 100. Tongue with slight coat. No abdominal pain. One normal dejection to-day.

*Fifty-sixth day.*—Feeling quite well, but has occasional pain in the right hip. Pulse still 100. Skin quite hot. Spleen to be felt below the ribs on full inspiration.

*Sixtieth day.*—Feels nicely, and wishes to sit up. Pulse 98.

*Sixty-second day.*—Does not feel so well to-day. Pulse 98.

*Sixty-sixth day.*—During the four previous days I had not seen the patient, but on visiting him I learned the following history. During the whole of the day of my last visit to the patient, and also during the following day, he continued to feel unwell. Was dull and feverish. During both days he kept his bed. On the morning of the sixty-fourth day, he ate for breakfast a small piece of milk-toast. For dinner, he sucked the juice from a small piece of beef-steak, and for supper he took only a cup of tea. After drinking his tea, feeling rather tired and sleepy, he directed his friends to retire from the room, as he desired to go to sleep. He then turned upon his right side, when he felt something give way in the abdomen, and at the same time experienced a violent pain in the right iliac region. The pain soon extended over the whole abdomen. The patient had rigors, followed by fever. After three hours of intense pain,

the patient got relief after taking two powders which were ordered by a physician who had been called in.

The next day he had, at times, severe pain in the abdomen, of the same character as on the previous night; had also several attacks of vomiting. Bowels were very tender to the touch.

On the following day, the sixty-sixth from the commencement of the fever, and the second day after the appearance of these urgent symptoms, I saw the patient again. He was in bed, lying on his back, with the lower extremities drawn up. His countenance was expressive of great pain and prostration. The abdomen was somewhat tympanitic and tender to the touch. No dulness of the abdomen was detected on percussion. Skin warm and moist. Tongue dry and red. Pulse 90, regular, but weak. Respirations 24. Patient had already vomited several times during the morning, and had been much troubled with flatulence. Upon the recommendation of a so-called doctress, he had taken some castor oil and an enema. Several copious dejections followed their administration. The patient was directed to remain absolutely quiet, and in the supine position. Opium was given in one-grain doses every four hours. Beef-tea was ordered to be taken in small quantities.

*Sixty-seventh day.*—Slept quite well last night. Is now fully under the influence of opium. Abdomen more tympanitic. Some dyspnoea. Pulse 96. Tongue dry. Respirations 96. Warm turpentine stupes were directed to be placed over the abdomen.

*Sixty-eighth day.*—A comfortable night. One natural dejection this morning. Abdomen still more tympanitic. Pulse 109. Respirations 26.

*Sixty-ninth day.*—A restless night. Much oppressed for breath. Abdomen excessively distended. Pulse 110, feeble. Respirations 32. Brandy, in small doses, was ordered. In the evening, when I saw the patient a second time, he was in great distress. The abdomen enormously distended. Tympanitic resonance extends nearly to the mammae. Hepatic dulness cannot be distinguished. Abdomen very tender to the touch. Has vomited several times during the day. Countenance is now collapsed. Intelligence good. Skin cool and moist. Pulse 136, very feeble. Brandy, in two-drachm doses, was ordered every half hour. The patient seemed to rally a little after the administration of the brandy, but towards morning he began rapidly to sink, and died.

All efforts to procure an autopsy proved unavailing.

In the above case we have nearly all the symptoms of typhoid fever. We have the prodroma of headache, dizziness, tinnitus aurium, malaise and anorexia; then we have the chill, the epistaxis, the rose spots, the bronchitis, the enlarged spleen, and the evening exacerbation of fever. The diarrhoea, the tenderness in the right iliac region and the delirium are only wanting to complete the category of symptoms of a typical case of typhoid fever. The patient made a good recovery, and one week after his apparently complete restoration to health, he was seized with the ordinary symptoms of sciatica. The sciatic pain soon subsided, leaving only the considerable fever and the enlarged spleen to lead to the suspicion that the typhoid poison still lingered in the system.

On the sixty-fourth day from the commencement of the sickness, and on the eleventh day after the second attack, and in the absence of diarrhoea or abdominal pain or tenderness or any other symptom pointing to a severe intestinal lesion, the patient was suddenly seized with a violent pain in the right iliac region, and there followed all the sad train of symptoms of a peritonitis occasioned by a perforation of the intestines.

Perforation of the intestines and consequent peritonitis is one of the most dreaded and fatal complications of typhoid fever. Perforation is quite as apt to occur in the mildest type of the disease as it is when the symptoms assume a far more violent character. The perforation occurs in those parts of the ileum occupied by Peyer's patches, and takes place either during the stage of sloughing or ulceration of these glands. The inflammation extends either directly to the peritoneum by means of the softening of the mucous and muscular coats of the intestines, or it approaches the peritoneum more slowly by means of the ulcerative process. The inflammation having reached the serous coat of the intestines, a local peritonitis is set up, lymph is thrown out, and in many instances the part in which the local peritonitis has arisen becomes adherent to some other portion of the peritoneal coat, and thus a perforation is prevented. In still other instances such an adhesion does not take place, the peritoneal coat is perforated and the contents of the intestines are thrown into the abdominal cavity and general peritonitis is induced. In this tendency of the peritoneal coat to throw out lymph and become adherent to the part immedi-

ately contiguous, we see a wise and conservative provision of nature, without which perforation in typhoid fever would manifestly far more frequently occur.

As regards the frequency of cases of perforation of the intestine in typhoid fever, we have the statistics of Heschl, who found in 1271 cases of death from this fever that perforation occurred 56 times, or in about 1 in 23 of the fatal cases. Murchison reports that of 270 fatal cases occurring in France, 25, or about 1 in 11 of the deaths, were due to perforation. Of 165 cases of death from typhoid fever occurring in England there were 35 perforations, or 1 in 5 of all the deaths were due to perforation. Of 703 cases of autopsies of typhoid patients in Germany, 70 perforations were found, or 10 per cent. The frequency of cases of perforation, at times, is worthy of note. At Tübingen Griesinger observed 4 cases of perforation in six years, 3 of which occurred in one year. At Zurich he observed 6 cases in one year with a small number of typhoid patients, while at another time during the space of thirteen months there occurred no cases of perforation, though the number of typhoid patients was very great. The same fact has been verified at Vienna. In 1843 the cases of perforation were in proportion of 1 to 10, in 1848 1 to 99, in 1858 1 to 25, in 1861 1 to 14. Perforation occurs twice as frequently in men as in women, and in children the percentage of cases of perforation is 1 in 100 of the cases of death.

It is not to be inferred that every case of peritonitis in typhoid fever is due to perforation of the intestines. Peritonitis may arise in the first stage of the fever from an excessive infiltration of Peyer's patches. It may arise from great enlargement, softening or suppuration of the mesenteric glands. It may be occasioned by the opening of an abscess in the spleen or wall of the bladder into the abdominal cavity. It may arise from a dysenteric or gangrenous process in the intestines, or finally it may occur spontaneously in the course of the fever, without any apparently exciting cause.

*Symptoms of Perforation.*—The symptoms by which perforation of the intestines and subsequent peritonitis become known in typhoid fever are usually quite characteristic, and very rapidly developed. Without any prodromic symptoms the patient experiences a sensation as if something had given way in the right iliac region. He is seized with a violent pain in this locality, which soon extends over the whole abdomen. Chills, fever and vomiting follow. The ab-

domen becomes tender to the touch, and at times excessively tympanitic. The patient does not throw himself about as in an attack of colic, but lies quietly in bed with lower extremities drawn up. All motion is avoided. Every effort, as in coughing, causes an expression of pain to come over the countenance. The patient speaks softly and avoids a deep inspiration on account of the pain which the movement of the intestines occasions him. The pulse becomes small and rapid. The countenance becomes collapsed, the extremities cool, and soon death brings relief to the sufferer. In other cases the symptoms are more slowly developed. In typhoid patients in a state of partial or complete unconsciousness, a sudden general collapse may be the first indication of the lesion which has occurred. In such cases excessive meteorism and the distortion of the countenance produced by pressure upon the abdomen, and especially in the ileo-cæcal region, are symptoms of great value in the diagnosis of the disease.

*Prognosis.*—The prognosis in cases of perforation of the intestines, is always extremely unfavorable, and in all cases of subsequent general peritonitis the prognosis is almost invariably fatal.

*Treatment.*—The most rational treatment would seem to be prophylactic. Whether the symptoms in typhoid are of a severe or a mild type, whether the disease is in its earlier stages, or convalescence has been established, this complication is the one most to be feared, and should be guarded against by every possible means. Especial attention should be devoted to the diet of the patient, and nothing should be taken into the stomach which will irritate this organ or any other portion of the intestinal canal. Whenever in the course of the disease the stomach becomes irritated or the discharges from the bowels become too frequent, these symptoms should be, if possible, promptly relieved. In cases, also, where the fever is complicated with bronchitis, the cough should be moderated, as undue exertion from coughing, vomiting, or straining at stool, or violent action of the intestines, may occasion a perforation of the peritoneum beneath an ulcerated Peyer's patch. On the same principle the patient should be cautioned against any undue exertion, and should not engage in his usual avocations till his former health has been fully restored. The only treatment which offers any chance of success after perforation has occurred, is absolute rest for the body, the withholding of all solid food and of any considerable quantity of fluid from

the stomach, the avoidance of all cathartics and clysters, and of everything which may provoke the peristaltic movement of the bowels, and finally the free administration of opium. This drug is our sheet-anchor in this fearful complication. Opium should be given in very large doses, and sufficiently often to perform the double office of keeping the intestines in a state of repose and of alleviating the excessive pain which the patient suffers.

### SEROUS CYST OF THE RECTUM.

By S. W. TORREY, Beverly, Mass.

ABOUT the first of January, 1869, I was called to examine an infant son of Mrs. C., of Beverly, for what was described as "a falling of the bowel," which had been observed from the time of birth, two months before. On first looking at the anus there was nothing abnormal to be seen, but as I held the nates widely apart the child was seized with a sudden spasmodic bearing down, and after a few screams there appeared at the anus a globular, fluctuating tumor, blocking up the whole passage, so that the feces, which were expelled at the same time, passed out in thin sheets between the tumor and the anterior wall of the rectum. A digital examination proved that the tumor was attached to the posterior wall of the gut—its lower extremity, except when the mass was forced down by the child, being an inch and a half above the verge of the anus, and its whole attachment nearly three and a half inches in circumference. On puncturing it with an exploring needle about an ounce of thin, serous fluid escaped, and a diagnosis of a serous cyst lying between the mucous and muscular coats of the rectum, was arrived at. The sac filled again rapidly, and in two weeks there was a renewal of the previous symptoms—viz., descent of the tumor during defecation, accompanied with agonizing pain—and added to this, increasing dilatation of the sphincter ani, which gradually lost its contractile power, from the continued pressure of the tumor upon it. There was also now a prolapse of the anterior wall of the rectum, and a considerable amount of inflammation of the mucous membrane, arising from continued contact with the clothing. Three weeks from the time of puncturing I passed a seton through the lower part of the tumor, hoping for adhesive inflammation and obliteration of the sac. This treatment bids fair to be permanently successful—the state of the case at

this date (May 21st) being as follows:—withering away of the cyst, rare appearance of the tumor outside the anus, perfect action of sphincter, no inflammation—the child gaining flesh, and as free from suffering as other infants of his age.

### REPORT OF A REMARKABLE CASE.

By AMOS SAWYER, M.D., Hillsboro', Ill.

DURING the spring of 1868, Mr. Adam Vettle, of Nokomis, Montgomery Co., Ill., bred a mare to his stallion. A few nights thereafter (he *thinks* a week), his jack "broke loose," and staid with the mare until morning—she still being in heat. This spring she gave birth to twins—one a *mule*, the other a *horse* colt; both alive and doing well.

May, 1869.

## Reports of Medical Societies.

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY.

CHARLES E. VAUGHAN, M.D., SECRETARY.

The annual meeting was held at Waltham, April 14th. After the usual business, the subject of autopsies ordered by coroners, and the collection of the established fees, was introduced. After an animated discussion, a committee of three was appointed "to wait upon the County Commissioners, to discuss the subject with them, with a view to establishing a basis for future action in such cases."

Dr. Hosmer, of Watertown, read a paper upon the *Abuse of the Alimentary Canal*, of which the following is an imperfect summary:—

Physicians are less liable to be called to account for errors in treatment than surgeons. This should make them more conscientious. An honest physician will often acknowledge to himself that he has erred in the past, and done harm instead of good, with the best intentions. He should, therefore, be careful that his present theories are correct, as far as careful, independent thought can make them so. We often accept tradition too blindly.

Do not many prescriptions, even of excellent practitioners, overlook the importance of integrity of the alimentary canal to health?

The day of heroic practice has gone by. The *materia medica* still retains a measure of the veneration of the past, although we acknowledge, in theory, that mere medica-

tion is not the most important part of treatment.

In desperate cases, the physician acknowledges that the patient's chance of life depends upon his vital power. Stimulants and nutritives take, then, the place of drugs.

How do we treat the phenomenon of cough, for instance? Inquiries show that into four fifths of the ordinary prescriptions for cough, squill and ipecac enter, often in large proportion. Senega, antimony and sanguinaria often occur. Can we show any tolerable proof that these so-called expectorants really act as such, or even affect cough favorably? Do we not use them in accordance with popular prejudice and tradition? (Cases quoted of expectorant treatment, in cough dependent upon nervous causes.)

Cough is a modified expiratory effort. It may be produced by—1st, Mechanical irritation. 2d, Pseudo-membranous or ulcerative affections of the larynx or trachea. 3d, As a general rule, all inflammations, acute or chronic. 4th, Dilatation of bronchi and emphysema. 5th, Affections of lung tissue, as tubercle, cedema, &c. 6th, Paroxysmal affections. 7th, Reflex action, or sympathy. 8th, Hysteria, &c.

Expectorants are vaguely said to stimulate the vessels of the lungs. Yet they can be applied to excessive or deficient secretion.

What does analogy show? We can see that evacuants may be useful in unloading an embarrassed alimentary canal; stimulants, in improving an enfeebled circulation, &c. How can expectorants be effectual against cough, which arises from many diverse causes? Examining these causes, we must conclude that they can only affect a cough arising from a bronchitis, acute or chronic. In such a case, if they increase secretion, must they not increase cough, which is an effort to remove an already existing accumulation? Is there not risk in increasing the amount of morbid secretion?

Secondly. Expectorants possess an emetic and cathartic action, sometimes in small doses. In large, they produce prostration, and even fatal gastro-enteritis. Even in small doses they have a strong tendency to produce nausea, impair appetite, retard digestion. They interfere with the nutritive process, upon which health depends.

The modern formula declares disease to be a state of deficiency of some of the elements of health. Convalescence involves

an increase of reparative process as compared with waste, which imposes an unusual tax upon nutrition. If  $R$  = chance of recovery,  $V$  = vital power, and  $D$  = disease, then  $R = \frac{V}{D}$ . Now, whatever diminishes  $V$ , or increases  $D$ , diminishes the value of  $R$ , i. e. the chance of recovery. Expectorants have a tendency to decrease the numerator. They are not inert.

Thirdly. Direct experience convinces me of the inefficiency of expectorants.

Fourthly. The testimony of patients, an indirect experience, confirms the same opinion.

Fifthly. Many systematic writers openly or covertly question the existence of such a class of agents.

Dr. Sullivan, of Malden, described a case of rigidity of the os uteri, which has been reported in the JOURNAL.

Dr. Willis, of Waltham, reported a case of convulsions occurring a week after labor. Condition had been good until seizure. No albuminuria. Case terminated fatally in coma.

#### AMERICAN MEDICAL ASSOCIATION.

(Continued from page 286.)

THE Committee on the Nomenclature of Diseases have the honor to report that it has examined the "Provisional Nomenclature of the Royal College of Physicians" of London, and is of the opinion that it is desirable for this Association to recommend and adopt the same for general use in this country, with such modifications as, on deliberate consideration, may appear to be necessary. The following resolutions are, therefore, submitted:—

1. *Resolved*, That a special committee of fifteen be appointed by the President to take this subject into deliberate consideration, and to report at the next annual session what alterations, if any, are necessary to adapt the proposed nomenclature to general use in the United States.

2. That this committee be authorized to fill up any vacancies which may occur upon it.

3. That the Committee on Publication be authorized to publish, for general distribution, one thousand copies of the English and Latin portions of this nomenclature, under the designation of the Proposed Nomenclature, prefacing the same with such remarks as may be deemed necessary to secure the criticism and co-operation of as large a number of American medical men as practicable.

4. That the committee hereby appointed be directed to draw the attention of the

Surgeon General of the army, of the Chief of the Bureau of Medicine and Surgery of the navy, and of the Superintendent of the Census, to the question of their official adoption of the proposed Nomenclature; to invite them to appoint whom they see fit to represent them on this committee; and to solicit such coöperation as may be necessary to accomplish the purpose desired, viz.: the final adoption of such nomenclature and classification as will receive the conjoint approval of the official medical bureaus of the Government and of the general profession.

STANFORD E. CHAILLE, M.D., Chairman.

*Committee*—S. E. Chaille, Louisiana; J. J. Woodward, United States Army; A. B. Palmer, Michigan; F. G. Smith, Pennsylvania; J. F. Hentis, Alabama.

The following Committee of fifteen was appointed:

Francis G. Smith, Chairman; J. J. Woodward, U. S. A.; R. F. Mitchell, Alabama; A. B. Palmer, Michigan; S. E. Chaille, Louisiana; L. P. Yandell, Jr., Ky.; Austin Flint, New York; Geo. B. Wood, Pa.; H. S. Dickson, Pa.; E. Jarvis, Mass.; Theo. Parvin, Ind.; W. M. McPheeters, Mo.; E. M. Snow, R. I.; N. Pinckney, U. S. N.

Dr. Gaillard, Ky., offered the following, with preliminary remarks:—

*Resolved*, That the adoption of a uniform rate of collegiate fees—\$120 being the maximum—be accepted as the sentiment and desire of this Association.

Dr. Logan, of Alabama, moved to amend by inserting \$140.

After considerable discussion, the fees were placed at \$120.

Special committee on the relative advantages of Syme's and Pirogoff's mode of amputating at the ankle—Dr. G. A. Otis, U. S. A., chairman; Dr. J. D. Holloway, of Louisville, Ky.

Proposed by J. J. Woodward. Approved.

Dr. Bemis presented from Dr. John Waters, of St. Louis, Mo., a paper on the Doctrines of Force—Physical and Vital.

Dr. A. M. Pollock, of Pennsylvania, presented this amendment to the constitution:

*Resolved*, That all county medical societies shall be required to elect a committee annually, whose duty it shall be to examine all applicants for admission as students under the tuition of its members, and that no member of any county medical society shall receive any such applicant until such applicant shall present a certificate from said committee, testifying that he has a good English education, and a sufficient knowl-

edge of Greek and Latin to enable him to pursue his studies with advantage.

Laid over under the rules.

Dr. Toner, D. C., moved that a committee on variola be appointed—Dr. Joseph Jones chairman. Adopted.

Dr. Pinckney, U. S. N., made statements respecting relative grades of rank. The paper was ordered to be spread on the minutes.

Association adjourned to meet at 9 o'clock, A.M., Friday, May 7.

FRIDAY, MAY 7, 1869.

The Association met at 9 o'clock, Dr. Baldwin in the chair.

Reading of the minutes omitted.

In yesterday's report, the paragraph which defines the rates of fees in medical colleges is corrected so as to read "the maximum was established at one hundred and forty dollars, and the minimum at one hundred and twenty-eight dollars."

Dr. Joseph Jones, Louisiana, presented a number of specimens of pathology, anatomy, and natural history. The explanations were very interesting, and received with applause.

On motion of Dr. F. G. Smith, of Pennsylvania, the following resolution was unanimously adopted by a vote of the members present, standing, as a mark of respect:

*Resolved*, That the thanks of the association are justly due and are hereby tendered to the President for the uniform kindness and courtesy with which he has presided over its deliberations, and to the Committee of Arrangements, the physicians and citizens of New Orleans for the generous hospitality and fraternal kindness with which we have been received and treated during our sojourn in their city, with the assurance that the memories of this visit will always be among the brightest and most enduring of our lives.

On motion of J. P. Moore, of Mississippi, the following preamble and resolution were adopted:

Whereas, the contract system is contrary to medical ethics;

*Resolved*, That all contract physicians, as well as those guilty of bidding for practice at less rates than those established by a majority of regular graduates of the same locality, be classed as irregular practitioners.

The following reports of the sections followed:

Section on Meteorology, Medical Topography and Epidemics reported. Paper

accepted and referred to the Committee on Publications.

Sections on Practical Medicine and Obstetrics reported and were accepted, and referred to Committee on Publications.

And the report on the training of nurses was accepted and the resolutions adopted.

Section on medical jurisprudence, hygiene and physiology reported. Committee continued for next year. Report accepted and referred to the Committee on Publications.

Section on Surgery proposed that their report be received without formality and be referred to the Committee on Publications. Adopted.

After being read, the report was accepted and ordered to be published.

Section on Psychology, the same disposition.

The President appointed Dr. J. M. Toner a committee of one, at Washington, D. C., to assist the Librarian of Congress to keep the books of the Association.

On motion for adjournment, the President delivered an address, which was unanimously accepted and ordered to be published in the transactions of the Association.

*Gentlemen*—Before I submit the motion just made, and which, when adopted, will practically close my official relations to this body, allow me to return you my most cordial and grateful thanks for the unvarying kindness which I have received at your hands. Whatever my future lot in life may be, the world holds no honors which to me can equal those conferred by you. The fraternal good-will which has so conspicuously marked your deliberations has been to me a matter of infinite satisfaction and pride, and will not be the least among the grateful memories which will gladden my heart as I may hereafter review the incidents of my official connection with you.

To win your judgment and approval, to hold up the dignity of fellowship, the usefulness of the association and the interest and prosperity of the profession at large have certainly occupied my most anxious thoughts since my elevation to this position; yet to cherish and promote the intimate and cordial relations of friendship between the individual members of this association against all sectional distinctions or geographical lines, has also been among the chief objects of my ambition and the earnest desires of my heart. Could I now believe that my efforts have contributed in the slightest degree to enlarging that harmony of sentiment and fraternal feeling which has been

so apparent throughout this meeting, I should feel that I had commenced at least to make some return for the great honor and kindness received at your hands.

It now only remains for me, gentlemen, to again express to you my thanks, to wish you a safe return to your homes and labors, a happy reunion with your friends and families, and to pronounce that sad word over which the heart of friendship would fain linger, as I bid you an affectionate farewell.

W. O. BALDWIN,

President A. M. A.

The Convention adjourned to meet in Washington, D. C., second Tuesday in May, 1870.

The Report closes with a description of a Steamboat Excursion enjoyed by the Delegates, which was evidently a most brilliant affair. Officials from outside the Medical Profession and ladies participated. The party landed at the celebrated plantation of E. Lawrence, Esq., where they were most handsomely entertained. On board the boat was music, dancing, feasting—apparently one continued round of festivities. Indeed, the reporter waxes so warm with sentimentality, that, our types not being "warranted to keep in any climate," we should be almost afraid to transfer his expressions to them. He closes with the following paragraph.—En.

With the return of the excursion to the city, the formalities attending the session of A. M. A. ended, and we are certain that we utter the sense of the entire party, that they have been gratified with every proceeding which has attended their visit hither. The courtesies, honors and attentions they have received, were peculiarly marked with the chivalry which characterizes the Southern people, and we hope that our guests may ever retain only pleasant reminiscences of their visit to this golden, beautiful and incomparable Crescent City. With many good wishes to them, we regretfully bid them adieu and *bon voyage*.

In the Provincial Hospital for the Insane, Halifax, N. S., the number of patients on the first day of the past year was 169; admissions during the year, 86; total, 225. The average daily number for the year was 190. Recoveries, 20, or 23 per cent. on the admissions. Deaths, 14, or 7.3 per cent. on the average number resident.

## Bibliographical Notices.

THE NOMENCLATURE OF DISEASES\*—*Drawn up by a Joint Committee appointed by the Royal College of Physicians of London.* Large 8vo. Pp. 327. With full Index. London: W. J. & S. Gollbourn. 1869.

WE received from London a few weeks ago a copy of this truly *great work*. Begun in 1857, it has occupied the time and thoughts of very many of the most eminent men in the profession, who, having been appointed from the various Colleges, Societies, and Departments, have labored untiringly through so many years, without pecuniary reward, to perfect this arduous undertaking—"a long, tedious, and difficult labor."

It contains a list of more than eleven hundred diseases, deformities, and injuries, grouped together according to their anatomical seats (singularly enough beginning with the small pox and ending with the large). Synonyms are given in five different languages—Latin, French, German, Italian, and English—a great service to whoever may have occasion to read or translate from any of these languages; and will greatly aid in "fixing definitely, for all places, the things about which medical observation is exercised, and in forming a steady basis upon which medical experience may be safely built."

That the book has defects undoubtedly will soon be discovered by the critics, and already it has been questioned whether it is not too elaborate for the busy practitioner. But there must of necessity be a beginning, and it is difficult to imagine how more care or labor could be bestowed in preparation, or a more judicious selection be made under the circumstances. It is to undergo decennial revision, when emendations, if required, can be made. "How far the Committee," says one of the reviewers, "have steered judiciously among the difficulties with which their path was beset, and how far they have been successful in their selection of names for use, time and the judgment of the profession will show. Meanwhile, it is manifest that, in their selection of names, as well as in their classification, their guiding principle has been convenience, rather than consistency; they have aimed, in fact, at making their nomenclature meet the re-

quirements of the profession at large, rather than at making it satisfy the critical few."

"The Nomenclature of Diseases" is published by authority of the Royal College of Physicians, and is now in full circulation throughout the United Kingdom. In order that every registered practitioner may have a copy, the British Government granted a gratuitous distribution of twenty thousand copies, at government expense, at a cost of seven or eight thousand dollars. This was done on the recommendation of Sir Thomas Watson and others, who stated to the Government that "many members of the medical profession, especially in the provinces, could not, from their needy circumstances, be expected to buy the book; though called upon by Government to give gratuitously certificates of death" (a picture, by the way, of the pitiable condition of the profession hardly to have been expected, even in England).

The Committee state in the preface that they have prepared a Nomenclature suitable to England, and to all countries where the English language is in common use. Would it not be for the public advantage to adopt the work at once, as a standard, in this country; that we may as soon as possible make sure that while using the same names we are speaking of the same things as our brethren in Europe?

A copy costs from two to three shillings sterling, according to binding; could not some enterprising bookseller import a "cheap edition"? Surely, few in the profession here are so badly off as not to be able to pay half a dollar in gold merely to gratify a laudable curiosity, if nothing more, in examining the results of the united labors of so many eminent men.

B. E. C.

## Medical and Surgical Journal.

BOSTON: THURSDAY, MAY 27, 1869.

### THE DOCTORATE OF MEDICINE.

A SLIP was some time ago sent us from the *College Courant*—the paper conducted by under-graduates of Yale College—consisting of a communication referring to the Medical School of that College.

It appears that in the year 1834, at the May session of the General Assembly of the State of Connecticut, an act was pass-

\* This paper was received by us before the report of the meeting of the American Medical Association, where reference was made to the topic of which it speaks.

ed, providing that the Medical Institution established in Yale College, "pursuant to an agreement between the President and Fellows of Yale College and the President and Fellows of the Medical Society of Connecticut, should be known and acknowledged by the name of 'The Medical Institution of Yale College.'"

"By the provisions of this act, there were to be not less than four nor more than six professorships established in the Institution, which were to be filled by persons nominated by a joint committee, appointed by the proper officers of the College, and the State Medical Society, and chosen by the President and Fellows of the College. This joint committee for making nominations, was to consist of an equal number of persons designated by the two parties to the 'agreement' referred to in the act, to wit, the College and the State Medical Society. The act provided for the necessary course of study to be pursued by the Medical student, and for the graduation of candidates for degrees; and here is precisely where the act in question is singularly *unique*, for a Medical Institution under the management of Yale College. A better designation of the Institution, under the act, would have been 'The Medical Institution of Yale College, under the management of the Medical Society of Connecticut,' for the act virtually confers upon the Medical Society the entire control and management of the Institution, so far, at least, as the conferring of degrees is concerned. What practical inconveniences have arisen from this singular provision of the act, I am not prepared, at this present writing, to say; but it is easy to see that they might be both numerous and vexatious.

"The committee for examining candidates for degrees is made to consist of the Professors of the Medical Institution of the College, and an equal number of the members of the Medical Society of the State; and the President of the Society is made, ex-officio, President of the examining committee, with a vote at all times, and a casting vote when there is a tie. And the Medical Society seems to have been so tenacious of its power to *control* the Institution, as against the Professors, in this matter of conferring degrees, that it was further provided, in case of the absence of the President from the examining board, that a President *pro tempore* should be appointed, with the same powers, by the members of the examining committee *chosen by the Med-*

*ical Society alone!* Another singular provision of the act, is the virtual limitation upon the President of the College against conferring any honorary degree of Doctor of Medicine, except upon the recommendation of the President and Fellows of the Medical Society.

"With a Medical Institution in Yale College, thus tied up and restrained of authority by such an unwieldy deliberative body as the Medical Society of the State, it is no wonder it should lack the vital force and energy of other similar institutions in the country. It matters not how successful and efficient the Medical Society may be in the matter of its own management, or how distinguished its position as compared with medical associations of other States; it manifestly has no capacity to superintend, much less control a Medical Institution like that of the Medical Department of Yale College. It might make a very good *legislative* body, but it is too cumbersome and unwieldy to exercise any *executive* function—the vital thing needed in all Medical Colleges."

It is easy to see that the regulation of the course of study as here described would not be likely to admit of sufficient flexibility to adapt the education of the student to the wants of his time. But, the examination for degrees by a Board more or less under the control of the State Medical Society, does not appear to us so objectionable. In fact, the only change we could wish in the arrangement for examination would be that of making the examiners consist entirely of a committee elected by the Medical Society. The most important and fundamental reform called for in this country, to secure to the public properly educated medical men, a reform sought by some of our most earnest and far-seeing educators, is a legal enactment in every State, placing the power of licensing or of authorizing to practise medicine in the hands of a Board of Examiners, who should be independent of the medical schools and colleges. In this way a check would be put to the cheapening of medical degrees, with the attendant depreciation of the standard of qualification, now too frequently the result of competition between different schools. The ceremony of conferring the diplomas would, then, perhaps require less mental reservation, when the Dean, *ore rotundo*, pronounces solemnly the

words *quos scio idoneos*. No one should be certified to the community as competent to practise so weighty a calling as medicine—to guard the lives of human beings—unless reasonably proficient in all its branches. What avails a knowledge of Theory and Practice to the medical man deficient in his surgical anatomy, when called upon to tie the femoral artery? or if not versed in midwifery, let his surgical skill be ever so great, how will he be able to meet the sometimes trying emergencies of the parturient process? Yet, is it not too often the case that a diploma is bestowed on one who can answer the interrogatories of a majority of the examiners before whom the candidate is required to appear?

At the last session of the American Medical Association it was proposed that the General Government should take the matter in hand, and determine the qualifications of medical practitioners for all parts of the United States. This proposal is well worth considering, and may, perhaps, be an improvement on the plan of having a separate board of examiners for each State. We do not array ourselves in opposition to it. But, it will be urged by some on the other side that each community—each State say—should be allowed to decide for itself what degree of Medical Education it is able to sustain. Such education costs money. The more advanced it is, the greater the expense incurred in acquiring it. Medical services have a market value in proportion to their supposed excellence. The metropolis attracts by its larger fees those whose ambition takes the widest scope. If, then, the laws provided that no man should practise medicine in any part of the United States whose learning and skill were not up to the level of a Paris *agregé*, many a country village with a *clientèle* of five hundred dollars per annum would be without its regular Doctor, while the old women, the quacks, and the patent medicine venders, would there have things all their own way. It would seem, then, that a National Board of Medical Examiners would have to adopt a standard not so high as to deprive the more scattered and poorer communities of reasonably educated medical advisers, while Massachusetts, for instance, would desire

a higher standard. We repeat the axiom, however, that whatever reform may be adopted, its fundamental principle should be that no one should be allowed to graduate in medicine who is *deficient in any of the branches of his calling*.

One other point we take this occasion to make. Medical education, we think, will never have a perfectly sound basis until Professors are made independent of the fees of their pupils—until each principal Professorship is established on a foundation ensuring adequate remuneration. No testamentary bequests would do more honor to the memory of the testator than such as would place the cardinal Professorships of an eminent Medical School on an independent footing. By the cardinal Professorships we mean those of Anatomy, Physiology, Materia Medica, Theory and Practice, Surgery, Obstetrics. A medical institution sustained in this way could raise its standard of education without consulting the number of pupils on its catalogue. And that standard being elevated, the best students—those intending to practise in the more favored communities—would seek the benefits of its instruction and the indorsement of its recommendation. Its examinations would render the inquisition of any general board of scrutiny a mere matter of form to its graduates.

#### MASSACHUSETTS MEDICAL SOCIETY.

MEMBERS are reminded that the annual meeting occurs next week.

#### PROGRAMME FOR TUESDAY, JUNE 1ST.

Ten o'clock, A.M. Operations, Surgical Visit, and Exhibition of Patients, at the Massachusetts General Hospital.

Ten o'clock, A.M. Operations, Surgical Visit, and Exhibition of Patients, at the City Hospital, Harrison Avenue, opposite Worcester Square.

Twelve o'clock, M. Meeting at Bumstead Hall (Music-Hall Building, entrance on Winter Street), where papers by the following gentlemen will be read:—1, Myxoma, or Hyperplasia of the Villi of the Chorion, by Alexander D. Sinclair, M.D., Boston; 2, General Management of the Insane, by Merrick Bemis, M.D., of Worcester; 3, Formation and Significance of Renal Casts, by Robert Thaxter Edes, M.D., Ilingham; 4, Physiological Action of Bro-

vide of Potassium, as determined by experiment on the lower animals and man, by Robert Amory, M.D., Brookline; 5, Microscopical Study of the Nervous System, by Samuel G. Webber, M.D., Boston. Adjournment at 2 o'clock.

Four o'clock, P.M. the Society will re-assemble in Bumstead Hall for the further reading of papers, and for their discussion. Adjournment at 6 o'clock.

During the afternoon the Warren Museum at the Mass. Med. College, North Grove Street, the Warren Museum of Natural History, 92 Chestnut Street, the Cabinet of the Med. Improvement Society, Perkins Building, and the Museum of the Boston Society of Natural History, Berkeley Street, will be open to the Society.

The Annual meeting of the Councillors will be held at the Rooms of the Society, Perkins Building, No. 12 Temple Place, at 7.30 precisely.

#### PROGRAMME FOR WEDNESDAY, JUNE 2D.

The Annual Meeting of the Society will be held in Bumstead Hall, Boston, at 10 o'clock, A.M., CHARLES G. PUTNAM, M.D., President.

*Order of Proceedings.*—1, Ordinary Business; 2, Reports of Committees; 3, Medical Papers and Communications; 4, A Case of Regeneration of Bone, by David W. Cheever, M.D., of Boston.

At 1 o'clock, precisely, the Annual Discourse, by ALFRED HITCHCOCK, M.D., of Fitchburg.

The Annual Dinner will be served in the Music Hall, entrance on Winter Street, at 2, P.M.

We are requested to say that The Institute of Technology will be open to members of the Society, on Tuesday afternoon, June 1st.

**CHROMIC ACID.**—In the *Bulletin Général de la Thérapeutique*, Dr. E. Magitot recommends *chromic acid* as an application to various affections of the buccal mucous membrane—such as all forms of stomatitis; and particularly the different kinds of gingivitis from that connected with dentition (as when, for example, it attends the eruption of a wisdom tooth), to ulcerative stomatitis. Aphthæ, and divers other ulcerations of the buccal mucous membrane, are also, he says, rapidly modified by this agent. But, the affection for which he specially recommends the acid is “alveolo-dental osteo-periostitis.”

**GANGRENE FROM EMBOLI.**—The *Archives Générales de Médecine* for March contains an account of an instance of embolism producing gangrene, reported by M. Gintrac—the patient a man of 75, previously in good health. It presents some points of analogy with the case of that affection reported in the number for May '20th of this Journal. There were marked points of difference, however, among the symptoms of the two cases. The seizure was sudden and in the night, in both. But, it was pain that opened the attack in the French case, while loss of motion was the prominent phenomenon in Dr. Lyman's case. In the former the power of motion was unimpaired to the last, and there was at first hyperæsthesia of the member first affected, followed in four or five days by insensibility. In the latter there was entire loss of motion and nearly complete loss of sensation from the first. In the latter there was some but not urgent pain in the calf of the leg. In the former the pain was lancinating and very acute—a cramp which ran up along the inside of the thigh.

In M. Gintrac's case both legs were gangrenous, the right having been attacked the 20th of May, 1868; the left four days, or rather nights, after. The report of the 25th of May was that the two lower limbs from knees to feet were cold, having a cadaveric feel. The temperature at the axilla was 38° (centigrade); at the knees, 32°; at the feet, 26°. The right leg and foot were insensible and blackish; the color of the left having become more purple. Respiration 36. Pulse 150, small and irregular. Same frequency and irregularity of heart's action. No pulsation felt in either femoral artery. Prostration very great. The patient died on the 28th, eight days after the first attack.

At the autopsy there were found in the left ventricle of the heart, which was softened, vegetations—some rounded, others pediculated. In the right ventricle there was a large, softened, and apparently recent, clot. The descending aorta contained an elongated clot, occupying nearly half the calibre of the vessel. At two fingers' breadth from the bifurcation of the aorta, there was a second clot, extending the en-

tire length of the right common iliac artery, and terminating inferiorly at the origin of the hypogastric, into which it sent a slender offshoot. It was greyish, fibrinous, non-adherent to the arterial wall. The external iliac was completely plugged by a "fibrinous concretion" analogous to that found in the heart. This plug adhered firmly to the artery. The left common iliac and left external iliac were very similarly obstructed. Other clots were found in the arterial ramifications of both lower extremities. The lining membrane of the arteries and veins of both lower limbs showed no trace of disease.

THE AMERICAN JOURNAL OF PHARMACY ON SVAPNIA.—Professor Procter—the Editor of the *American Journal of Pharmacy*—has been making experiments upon Svapnia, and gives in the May number of his Journal quite an elaborate account of them. He seems not to sustain some of the chief merits claimed for the preparation by its originator. Professor Procter justly remarks:—

"The argument for keeping svapnia a specialty has a certain degree of merit; it is true that novelties in pharmacy, even good novelties, are imitated by the unskilful, and for a time, especially if the manufacture is difficult, some public advantage may accrue from this primary uniformity. But we argue that in drugs like opium, or cinchona, or ipecac, all should be open and untrammelled in pharmacy. Did Sertürner patent morphia? or Pelletier and Caventon quinia and strychnia? But into these views business men do not care to enter."

If medical men will read this and similar papers in the *American Journal of Pharmacy* they will be convinced that Pharmacy has arrived at the position of a scientific specialty.

THE MEDICAL PROFESSION IN MASSACHUSETTS.\*—We have been favored with a copy of this paper, through the kindness of the author, whose name is a guarantee of its value. The beauty of its dress is sufficiently set forth by the name of its printer.

We make the following extracts:—

\* A Lecture of a Course by members of the Massachusetts Historical Society, delivered before the Lowell Institute, Jan. 29, 1869. By Oliver Wendell Holmes. Boston: Press of John Wilson & Son. 1869.

"I have illustrated the practice of the first century, from the two manuscripts I have examined, as giving an impartial idea of its every-day methods. The Governor, Johannes Secundus, it is fair to remember, was an amateur practitioner, while my ancestor [Dr. James Oliver] was a professed physician. Comparing their modes of treatment with the many scientific follies still prevailing in the Old World, and still more with the extraordinary theological superstitions of the community in which they lived, we shall find reason, I think, to consider the art of healing as in a comparatively creditable state during the first century of New-England. \* \* \* \*

"The name of Thomas Sydenham is as distinguished in the history of medicine, as that of John Locke in philosophy. As Barbeyrac was found in opposition to the established religion, as Locke took the rational side against orthodox Bishop Stillingfleet, so Sydenham went with Parliament against Charles, and was never admitted a Fellow by the College of Physicians, which, after he was dead, placed his bust in their hall by the side of that of Harvey.

"What Sydenham did for medicine was briefly this: he studied the course of diseases carefully, and especially as affected by the particular season; to patients with fever he gave air and cooling drinks, instead of smothering and heating them, with the idea of sweating out their disease; he ordered horseback exercise to consumptives; he, like his teacher, used few and comparatively simple remedies; he did not give any drug at all, if he thought none was needed, but let well enough alone. He was a sensible man, in short, who applied his common sense to diseases which he had studied with the best light of science that he could obtain.

"The influence of the reform he introduced must have been more or less felt in this country, but not much before the beginning of the eighteenth century, as his great work was not published until 1675, and then in Latin. I very strongly suspect that there was not so much to reform in the simple practice of the physicians of the new community, as there was in that of the learned big-wigs of the 'College,' who valued their remedies too much in proportion to their complexity, and the extravagant and fantastic ingredients which went to their making.

"During the memorable century that bred and bore the Revolution, the medical profession gave great names to our history. But John Brooks belonged to the State,

and Joseph Warren belongs to the country and mankind, and to speak of them would lead me beyond my limited subject. There would be little pleasure in dwelling on the name of Benjamin Church; and as for the medical politicians, like Elisha Cooke in the early part of the century, or Charles Jarvis, the "bald eagle of Boston," in its later years, whether their practice was heroic or not, their patients were, for he is a bold man who trusts one that is making speeches and coaxing voters, to meddle with the internal politics of his corporeal republic.

"At some time in the course of this century, medical practice had settled down on four remedies as its chief reliance. When Dr. Holyoke, nearly seventy years ago, received young Mr. James Jackson as his student, he pointed to the label drawers and bottles all around his office—for he was his own apothecary—and said, 'I seem to have here a great number and variety of medicines; but I may name four, which are of more importance than all the rest put together; namely, Mercury, Antimony, Opium, and Peruvian Bark.' I doubt if either of them remembered, that, nearly seventy years before that, in 1730, Dr. William Douglass, the disputations Scotchman, mentioned those same four remedies, in the dedication of his quarrelsome essay on inoculation, as the most important ones in the hands of the physicians of his time. \* \* \*

"I am not disposed to deny the occasional injurious effect of the materializing influences to which the physician is subjected. A spiritual guild is absolutely necessary to keep him, to keep us all, from becoming the 'fingering slaves' that Wordsworth treats with such shrivelling scorn. But it is well that the two callings have been separated, and it is fitting that they remain apart. In settling the affairs of the late concern, I am afraid our good friends remain a little in our debt. We lent them our physician Michael Servetus in fair condition, and they returned him so damaged by fire as to be quite useless for our purposes. Their Reverend Samuel Willard wrote us a not overwise report of a case of hysteria; and our Jean Astruc gave them (if we may trust Dr. Smith's Dictionary of the Bible) the first discerning criticism on the authorship of the Pentateuch. Our John Locke enlightened them with his letters concerning toleration; and their Cotton Mather obscured our twilight with his *Nishmath Chajim*. \* \* \*

"We have seen it [the medical profession] in the first century divided among clergymen, magistrates, and regular practitioners; yet, on the whole, for the time, and under

the circumstances, respectable, except when it invoked supernatural agencies to account for natural phenomena.

"In the second century it simplified its practice, educated many intelligent practitioners, and began the work of organizing for concerted action, and for medical teaching.

"In this, our own century, it has built hospitals, perfected and multiplied its associations and educational institutions, enlarged and created museums, and challenged a place in the world of science by its literature.

"In reviewing the whole course of its history we read a long list of honored names, and a precious record written in private memories, in public charities, in permanent contributions to medical science, in generous sacrifices for the country. We can point to our capital as the port of entry for the New World of the great medical discoveries of two successive centuries, and we can claim for it the triumph over the most dreaded foe that assails the human body—a triumph which the annals of the race can hardly match in three thousand years of medical history."

---

CLASTIC ANATOMICAL MODELS.—A course of lectures has just been delivered at the Lowell Institute by F. G. Lemerrier, M.D., of Paris, "coöperator" of Dr. Auzoux, and Professor of the Polytechnic Association of Paris. The lectures were illustrated by, and in illustration of the preparations called "clastic anatomical models" made by Dr. Auzoux, of Paris. Dr. Lemerrier has representations—we are told—of all manner of things—man, woman, the gorilla, the horse, fish, bugs, snails, leeches, boa-constrictor, &c. &c.—numbering one hundred and fifty at the least calculation. His preparations are spoken of as promising to be valuable in assisting teachers of the subjects they illustrate. The models of plants, greatly magnified, have been particularly commended as useful to instructors and students of botany.

Dr. L., we are told, does not offer for sale less than his whole collection; but sends orders for copies of any of the models to Paris, whence they are forwarded. We have sought and give this information in the interest of scientific instruction. To procure any of these articles parties may

address Dr. F. G. Lemer cier—care of V. Colyer, Esq., curator of Cooper Institute, New York.

At the Pathological Society, London, Dr. Hermann Beigel exhibited a Living Specimen of Skin Disease hitherto not described, and to which he gave the name of Papilloma area-elevatum. The patient was a male child, twelve months of age, and born of healthy parents. The mother had noticed that different parts of the child's body became covered with small pimples of the size of a pin's head, which soon increased and formed patches, the largest about an inch and a quarter in diameter. These patches were raised above the surrounding skin, the latter not being inflamed. The patches were of a round shape, and their surface was smooth, as if covered with healthy skin. Others, particularly those on the face, were covered with a thin scab, which, when removed, showed a surface resembling a sponge, the effect of much hypertrophied infiltrated papilli discharging small quantities of serum and pus. On cutting with a knife or scissors, the patches proved nearly insensible, the child exhibiting no signs of pain. The microscope showed a great abundance of epithelial formation, the papilli being either extensively infiltrated or broken down. The child had not been, and was not, feverish, his health was pretty good, and he had no cachectic appearance. Dr. Beigel thought that this form of skin disease which he brought under the notice of the Society had not been described. The name he applied to it was intended to indicate the most prominent symptoms—namely, that the papilli are principally affected, and that the skin affection is of a round shape, areated, and raised above the level of the surrounding skin.

Dr. Tilbury Fox remarked that the appearance was due to sessile warts—a condition described by Dr. McCall Anderson as eczema marginatum. No new name was needed.

Dr. Hilton Fagge thought it rather unusual. There was a model in Guy's Museum like it.

Dr. Langdon Down had that day seen a similar case in the London Hospital.—*Medical Times and Gazette*.

REMARKABLE CASE OF AMENORRHEA. — (*Wiener Med. Wochenschrift*, xviii. 33, 1868.)

An apparently healthy woman, 31 years of age, married for 11 years, has, up to the present time, passed through six normal

confinements, in neither of which the usual loss of blood or lochial flow took place. *This woman had never yet menstruated* until after weaning her last child, when the catamenia appeared for the first time in her life, and reappeared after four weeks.

The only sign of conception was the nausea and vomiting, constantly occurring in the first few weeks.—*Jour. of Obstetrics*.

SUBCUTANEOUS MEDICATION FOR SYPHILIS.—In No. 14 of this JOURNAL we referred to Dr. Max Van Mons's application of Scarenzio's method. We are now able to give the following further particulars:—

A common subcutaneous syringe, having a capacity of from 7 to 10 drops, or more, is charged with a dose of from 10 to 40 centigrammes of calomel suspended in a very dilute mucilage of gum-arabic. This is injected into the subcutaneous tissue; an abscess follows, "of about the size of a hen's egg," which may be opened on the 8th or 10th day. One injection is almost always sufficient. All local treatment of the syphilis is suspended. Twenty-two cases (we spoke of only five in the previous notice) have been thus treated; salivation occurring in but one instance.

D. F. L.

POISONING BY STRAMONIUM SEED.—Dr. J. F. Freeman reports, in the *Chicago Medical Journal*, the following cases of poisoning: He was called to see a mother and two daughters, who had had paroxysms of ague, and had taken, as they supposed, fennel seed, but it proved to have been stramonium seed instead. When first seen the mother and daughter were raving like maniacs, while the other was rapidly sinking into coma. Tinctura opii was at once given, and morphia injected subcutaneously. The youngest girl recovered rapidly, but the others only after having taken several large doses of morphia. The recovery in each case was complete.—*Med. Record*.

CINCHONA IN JAMAICA.—From 8,000 to 10,000 plants of *cinchona succirubra* are ready for sale in the island of Jamaica, at the plantation at Gordon Town, this spring.—*Ibid*.

"TITRATION."—"Averaging" is the old term. A quantity of opium (e. g. 100 lbs.) is powered *en masse*, giving a morphine percentage of 7-10. Titrated fluid extract, made from this, is brought to a standard strength by adding morphia.

## Medical Miscellany.

**MASSACHUSETTS DENTAL SOCIETY.**—The annual meeting of the Massachusetts Dental Society was held on the 24th inst. in the hall of the Society, No. 12 Temple place, the president, E. G. Leach, D.D.S., in the chair.

The reports of the president, treasurer, and librarian of the society were read and accepted, after which the election of officers took place, with the following result:—

*President*, Dr. T. H. Chandler.

*First Vice President*, Dr. G. L. Cook.

*Second Vice President*, Dr. J. A. Salmon.

*Recording Secretary*, Dr. A. Brown.

*Corresponding Secretary*, Dr. E. Blake.

*Treasurer*, Dr. J. T. Codman.

*Librarian*, Dr. J. T. Moffatt.

*Microscopist*, Dr. T. B. Hitchcock.

The following delegates were then elected to attend the National Convention of Dentists to be holden at Saratoga on the 1st of August:—Drs. Hawes, Blake, Leach, Walters, Ham, Cook, Chandler, Stearns, Osgood, Thompson and Adams.

The usual committees were also chosen, after which the orator for the next year was balloted for, and Dr. L. D. Shepard was elected, and Dr. E. Blake appointed substitute.

At 12½ o'clock the annual address was delivered by Dr. A. A. Cook, of Milford; his theme being "The Coming Man of the Dental Profession."

The reading of essays followed the delivery of the address. Dr. T. H. Chandler read an essay on the subject of "Comparative Anatomy of the Teeth," and Dr. T. B. Hitchcock on "The Tarsar of the Teeth." Dr. J. T. Moffatt exhibited and explained an interesting case where a piece of the tooth of a boy 14 years of age, which had been broken off, was placed in its original position, and the tooth grew strong again. Dr. E. G. Leach also made some remarks in reference to cleaning teeth.

The society then adjourned at half-past three o'clock to the Tremont House, where the annual dinner was served. After dinner, speeches were made at the table by Drs. N. C. Keep, L. D. Shepard, Kidder, E. G. Leach, T. B. Hitchcock. Dr. J. T. Codman also read a humorous poem written for the occasion. The Society afterwards assembled in one of the parlors of the Tremont House, and an essay on "Dental Nomenclature" was read by Dr. J. T. Codman.

**MASSACHUSETTS BENEVOLENT SOCIETY.**—At a late meeting of the Council of the Massachusetts Medical Benevolent Society, its financial condition was stated to be excellent, and a considerable number of gentlemen from various parts of the State were elected members. All information concerning the object and the success of the Society's operations may be obtained from the Treasurer of the Mass. Medical Society at the time of the annual meeting in June.

**NORFOLK DISTRICT MEDICAL SOCIETY.**—Dr. Joseph Stehman, of Jamaica Plain, was chosen *Censor*. His name was accidentally omitted from the list furnished us last week.

Why is the Northern part of Maine like "the small of the back"? Because it is the lumber (lumbar) region!

Prof. Humphrey, of Cambridge, has published a lecture on the subject of *torsion*. He has for several months past abandoned the use of aen-pressure, and has *used torsion in all cases exclusively*, for stopping hemorrhage, meeting with the best results, even in amputations of the thigh or leg.—*Amer. Jour. of Obstetrics*.

**OPIMUM EATING.**—Mr. Horace Day, of New Haven, the reputed author of "The Opium Habit," has eaten over fifty pounds of opium. He discarded the habit in less than six weeks after he had "made up his mind."—*Medical Record*.

**TYPHOID CUTANEOUS SPOTS.**—The occurrence, in conjunction with an unusually copious roseolar eruption, of another one of a yellowish-brown color of the size of a two-dollar piece and over, is described by Zulehaur (*Berliner Klin. Wochenschr.*). The latter spots run into one another. They were only observed in very severe cases, which in the first, or in the commencement of the second seven days' period, terminate in death.—*Medical Press and Circular*.

**PATENT MEDICINES IN ENGLAND.**—Stamp-duty was paid in the year ending March, 1868, on no less than 8,060,754 packets, boxes, &c., of medicines, selling at one shilling or more. The tax produced £62,556.—*Medical Record*.

## MEDICAL DIARY OF THE WEEK.

MONDAY, 9, A.M., Massachusetts General Hospital, Med. Clinic. 9, A.M., City Hospital, Ophthalmic Clinic.

TUESDAY, 9, A.M., City Hospital, Medical Clinic, 10, A.M., Surgical Lecture. 9 to 11, A.M., Boston Dispensary. 9-11, A.M., Massachusetts Eye and Ear Infirmary.

WEDNESDAY, 10, A.M., Massachusetts General Hospital, Surgical Visit. 11 A.M., OPERATIONS.

THURSDAY, 9 A.M., Massachusetts General Hospital, Medical Clinic. 10, A.M., Surgical Lecture.

FRIDAY, 9, A.M., City Hospital, Ophthalmic Clinic; 10, A.M., Surgical Visit; 11, A.M., OPERATIONS. 9 to 11, A.M., Boston Dispensary.

SATURDAY, 10, A.M., Massachusetts General Hospital Surgical Visit; 11, A.M., OPERATIONS.

TO CORRESPONDENTS.—The following communications have been received:—Exhaustive Uterine Hemorrhage—Obstetrical Society Records—Case of Movable Cartilage in the Knee-joint—Case of Syph. Dis. Brain.

DEATHS IN BOSTON for the week ending Saturday noon, May 22, 110. Males, 54—Females, 56.—Accidents, 4—anemia, 1—asthma, 11—congestion of the brain, 1—disease of the brain, 2—inflammation of the brain, 1—bronchitis, 8—burns, 1—cancer, 1—consumption, 16—convulsions, 1—cystitis, 1—debility, 2—diphtheria, 1—dropsy, 1—dropsy of the brain, 3—erysipelas, 1—scarlet fever, 8—typhoid fever, 2—gastritis, 1—disease of the heart, 2—intemperance, 2—jaundice, 1—disease of the kidneys, 2—disease of the liver, 1—congestion of the lungs, 5—inflammation of the lungs, 9—marasmus, 6—measles, 1—old age, 3—pleurisy, 1—premature birth, 3—puerperal disease, 1—purpura hemorrhagica, 1—rheumatism, 1—scrofula, 1—suicide, 1—teething, 1—unknown, 7—whooping cough, 4.

Under 5 years of age, 37—between 5 and 20 years, 7—between 20 and 40 years, 21—between 40 and 60 years, 18—above 60 years, 17. Born in the United States, 79—Ireland, 19—other places, 12.

## Original Communications.

## THE PHYSIOLOGICAL AND THERAPEUTIC RELATIONSHIPS OF ERGOT OF RYE.\*

A Thesis for the Degree of Doctor of Medicine; and to which was awarded the First Prize of the Boylston Medical Society for 1869.

By FRANK W. DRAPER, M.D.

ONE of the first embarrassments which the student of medicine meets, and that almost at the outset of his course, is the great number and variety of the remedies presented, in the *Materia Medica*, for his study and use. The implements of his profession confuse him, alike by their multiplication and their complexity. From all regions of her great domain Nature gathers her remedial stores, and offers them, with profligate generosity, to him who will choose to employ them. Chemistry adds new products, and pharmacy evolves changes without number.

This unlimited variety, characterizing the *Materia Medica*, it is the tendency of the present medical generation to modify. Simplicity of treatment is now deemed more rational than studied complexity, and all the innovations which this century has witnessed are marked by this tendency. As compared with the customs of the fathers, the opposite extreme seems almost reached in a proper zeal in behalf of the restorative power of Nature. The professional verdict declares for the use of a limited number of remedies which are well understood, and bases its dictum on the revolutionized sentiment with regard to the treatment of disease. It is to the renewal of life that our remedies are to be directed, not to the exorcism of disease. Hence comes the dogma of expectancy. The natural history of diseases is more carefully observed and better understood, and men see that nature may be guided and aided, but not forced.

As the direct result of this advancement, come more rational methods of study into

the intimate nature and relationships of the means to be used for the accomplishment of the end in view. It is part of the business of modern science to examine carefully into the processes which individual drugs produce, to see what virtue may be in them, to take them out of the hands of empiricism, and to apply them, on well-established principles of action, to the treatment of disease.

It is proposed, in this paper, to present some of the more recent views of the physiological and therapeutical relationships of a pathological product of the vegetable kingdom—the *secale cornutum*.

The use of ergot as a therapeutic agent is by no means of modern date. Although there is no evidence that it was employed by the ancients, or that they recognized its virtues, it is well authenticated that scientific men of the middle ages were not ignorant of its powers. As early as A.D. 1096 it was mentioned and described by medical writers, and at a still earlier period its efficacy, under proper conditions, as a parturifacient, was known by the continental midwives and empirics.

It was not, however, until the middle of the last century that physicians consented to admit ergot into the list of the legitimate *materia medica*, and this recognition, at so recent date, was attended with even considerable difficulty. Its use was interdicted in France in 1774; but it was again introduced soon after, on this occasion with favor and with the royal seal of professional recommendation. Like most remedial agents, however, its success was variable until it could outlive the prejudicial conditions of novelty and the want of extended trial; and for half a century after its introduction among regular practitioners it was hardly heard of. But at the beginning of the present century, it fell to the lot of an American to put the use of ergot on a permanent basis as a therapeutic agent, and the name of Dr. Stearns, of New York, is thus associated with its early history. Since this time it has constituted a subject for scientific discussion of very great importance. Writers upon its powers have mul-

\* Prof. E. H. Clarke specially recommended this paper to us for publication, and it was furnished at our solicitation.—Ed.

tiplied, until the bibliography pertaining specially to ergot has acquired almost indefinite proportions. Its chemical composition, its natural history, its mode of action, its therapeutic uses and abuses have been made the subjects of inquiry, resulting in the most diverse opinions concerning its powers, its virtues and its ill effects. As has been the case with many, perhaps with most, of the really valuable remedial agents in their primitive history, ergot was thus in danger of an early decline, both in consequence of the disastrous effects resulting from its abuse in inexperienced hands, and as the result of the violent partizan opinions to which its use gave rise. In the light, however, of the best modern experience, developed from the skilful observations of such men as Parola, Bonjean, Wright and Brown-Séquard, this article properly assumes a place among the agents placed at the disposal of mankind for the relief of suffering, and it is thus rescued from the abuses of empiricism, since its manifold and often apparently contradictory indications are made to rest on a rational physiological and pathological basis.

Into the consideration of the general character, the mode of growth, and the botanical relationships of ergot, it is not proposed to enter in this paper. The chemical constitution, moreover, is as yet a vexed question among pharmacists; new constituents are discovered and urged as the active principles, and new characters serve to confuse the already accumulated mass of chemical facts.

Leaving, then, the study of the natural history and of the chemical constitution of ergot, we pass at once to the discussion of its physiological and therapeutical effects. For the more systematic consideration of its powers, it is proposed to adopt the plan as illustrated in the examination of kindred topics (Prof. E. H. Clarke's Lectures on the *Materia Medica*), and to investigate, in turn, the absorption of ergot, its passage through the system, the effects during its passage, its *modus operandi*, and, finally, the therapeutic uses and indications.

*Absorption.*—It is sufficiently clear that the active principle or principles of the *secale cornutum* must first be introduced into the system, by the circulation, before the well known and most obvious effects can manifest themselves. Experiments are numerous to prove that the specific action can take place only through this medium. When ergot is applied artificially to any part not in direct communication with the circulatory system, its action, so far as

known, is neutral, or at best but negative. Nor is there reason to suppose that we have any subtle narcotic principle, which by sympathetic nervous transmissibility or by reflex action affects parts at a distance from each other, as some authorities suppose to be the case in tartar emetic or in some of the active poisons. But we are justified by the strongest analogy in placing ergot with the very large class of medicines which must "obtain entry into the blood or internal fluids of the body before their action can be manifested."—(Headland on the Action of Medicines, p. 59.) Chemistry, too, although as yet in a crude and imperfect manner, assists in the demonstration of the absorption of ergot, its presence in the blood having been determined by Wright, in 1840.

The action of ergot is essentially the same, by whatever avenue of absorption it reaches the blood. Applied locally in external hæmorrhage, as in epistaxis, its action is still the same as when it is exhibited by the more indirect process of absorption in the stomach; by its vital action on the bloodvessels, instead of its chemical effect on the blood, it claims a place "in the first rank of liquid hæmostatics which do not coagulate the blood, its action being wholly dynamic."—(Bonjean, "Ergotine," p. 11.) It has also been found that when the drug is administered by the rectum in the form of suppository, or as an enema; by the vagina, or by any of the mucous surfaces, absorption, although slow, is certainly followed by positive results, distant as well as local. Nor must it be forgotten that equally with other media of absorption, the stomach, obviously the most ordinary and convenient organ for the process, presents the active principle of ergot to the blood, with a consequent ready manifestation of effects identical with those produced after administration through other tissues. The numerous experiments of Wright have demonstrated, also, that the effects of the drug are the same on animals, whether it be presented directly to the blood by injection into the large veins, or indirectly by osmosis.

Another, but less obvious confirmation of the absorption of spurred rye is found in the effect of the drug in certain cases on the foetus in utero. In discussing the use of this agent in parturition, Dr. Beatty (Contributions in Midwifery—art. Ergot) remarks that children, still-born after the exhibition of ergot to the mother in labor, vary very much in their condition and appearance from those born dead under

ordinary circumstances, and he attributes this difference not only to the mechanical causes, but, in many cases, "to the noxious influence of ergot exerted on the nervous system of the infant" through the mother. The distinguishing characteristics of the former state he indicates as follows: "general lividity of the surface, universal rigidity of the muscular system, producing the stiffened limbs and clenched hands in those infants in which life was extinguished, and the remarkable kind of alternating spasm and palsy which supervened in those which were resuscitated." These differential phenomena occurred, according to this author, after sufficient time had elapsed, in each case, to permit the influence of the ergot to permeate alike the maternal and the foetal systems. It is not difficult to trace a marked analogy between the symptoms of ergotism thus manifested in the child, and the effects produced under ordinary physiological conditions, to be hereafter described.

The time occupied in the absorption of ergot through the healthy mucous membrane and tissues of the stomach, before it reaches the blood, is variously estimated. That it is rapidly taken up, under favorable conditions, is sufficiently clear. Thus it is stated by Churchill (*Midwifery*, p. 263) that sixty grains of the powder of ergot administered in tedious labor, will manifest effects in from five to ten minutes, "the pains becoming stronger, longer and more frequent." In experiments reported by Parola (*Bibliothèque du Méd. Pract.*, p. 218) symptoms referable to the action of spurred rye were observed in a healthy adult male in two hours; and again in experiments on himself, nausea, headache, general lassitude and other indications of ergotism manifested themselves in one hour after taking fifteen grains of the powder. "Arnal's numerous experiments showed that the action of a drachm of ergot commenced within an hour." (*Stillé—Therapeutics*, vol. ii. p. 586.) Gubler states (*Commentaires Thérapeut.* p. 112) that "after an interval of ten minutes the characteristic phenomena of this convulsive poison may be seen to exhibit themselves." Upon animals the effects are much more rapid and decided. Well marked symptoms appear in from five to ten minutes, in the case of dogs, after the ingestion of large doses of ergot in powder. (Wright, *op. cit.*)

Of the changes which the drug undergoes in the stomach, before absorption, by which only the active and assimilable portion is selected, while the rest is rejected to be

passed on through the intestines, we have no demonstration. Nor is it positive that the stomach is alone engaged in the process of elaboration and of absorption; it is tolerably certain, indeed, that the extensive mucous tract of the intestines, containing myriads of absorbents, may have some share. Whether, in this process, the tissues engaged in osmosis are subjected to any local effect, is also a question yet to be decided. It seems clear, however, that no positively irritant effect is produced, and that whatever local changes result, are only transitory and unimportant. "If the dose is sufficiently large, the subject is not slow in experiencing nausea and vomiting, which may be considered as symptoms of a promptly generalized action." (Gubler, *loc. cit.*) Applied externally to the skin, ergot does not appear to produce any sensible effects whatever, but if placed on an abraded surface it gives rise to profuse sloughing, the ulcers formed producing an abundant and offensive purulent discharge, and proving very slow to heal. (Wright, *Edin. Med. and Surg. Journal*, vol. liii. p. 8.)

There are, of course, conditions by which the absorption of this, in common with all drugs, is essentially modified. For example, the state of the system in general, whether of stimulation or of depression, the amount of the dose, the degree of its dilution when administered or subsequently in the stomach, depending on the relative fullness of that viscus, the idiosyncrasy, age, or habits of the patient, and, finally, the relative health of the medium of absorption, are all modifying conditions so obvious, and of such general application, that they need no extended discussion.

*Passage through the System.*—Once in the blood, the efficient constituent principles of ergot are conveyed by that fluid to every part of the system, thus exercising their legitimate effects everywhere, and giving rise to characteristic phenomena of action. What becomes of the drug in the passage through the system, whether its elements are resolved chemically, and used up in the blood, or are eliminated as they were absorbed, are questions yet open for solution. The experiments of Wright appear to indicate the presence in the blood of the oil of ergot, which Bonjean deems the poisonous element, but concerning the ultimate fate of this and of the other principles we are not yet enlightened. Nor do we know that any of the ordinary emunctories are concerned in the act of elimination. No increase of the secretions appears to indicate

the process, as is so plainly demonstrated with other agents; and we do not find functional or organic changes in the glands other than those referable to the general action. It has, however, been observed that the perspiration acquires a perceptibly sour odor after the injection of ergot. (Wright.)

We are equally uncertain concerning the time occupied by the processes of absorption and elimination, all observations being approximative only. Thus in labor, according to Trousseau and Pidoux (*Thérapeutique*—art. Ergot), the duration of the action of the drug varies from half an hour to an hour and a half. Prescott, after an analysis of fifty-nine cases, fixed the average duration of the effects at "an hour and a little more." But these sensible effects on the gravid uterus, although more obvious than phenomena developed elsewhere, do not probably indicate the only influence, or its actual extent and duration, while the cumulative effect is sufficiently shown by the symptoms in chronic ergotism, as well as by those pertaining to the nervous centres in the ordinary exhibition of the drug.

*Effects on the System.*—Experiments in this direction are reported in great numbers, although the results attained are essentially the same. A single observation recorded by Parola (*Bib. de Méd. Pract.* p. 218) will suffice in illustration. "A single man, aged 24 years, tall, slender, lymphatic and always healthy, took one gramme and a half of powdered ergot; his pulse being at the time sixty-seven, and his respiration twenty. Two hours after, he felt general depression, shivering throughout the body, coldness of the surface with 'goose-flesh,' illness at the epigastrium, loss of appetite; pulse sixty, soft and feeble; countenance pale; pupil dilated. On the day following, he took another dose, with the same effects somewhat aggravated; and during the next forty-eight hours, a feeling of debility, with slow pulse, and diminished respiration, showed the lasting depressing effect of the drug." Gubler (op. cit. p. 113) enumerates the symptoms of acute ergotism as follows:—"Nausea and vomiting, pain in the abdomen, alvine dejections, dryness of the fauces, thirst, aversion to food, itching of the limbs, numbness, lassitude, heaviness of the head, vertigo, dilatation of the pupils, delirium, drowsiness, stupor, rarely acceleration of the pulse, almost always, on the contrary, diminution in the frequency and force, tendency to syncope, pallor and lividity of the face." Nor must we forget the specific action of ergot, that for which it was first employed, whether empirically

or regularly, and which has given it nearly all the distinction which it possesses—its effects on the gravid uterus.

Experiments on the physiological effects on animals give results no less striking and interesting than those above enumerated. The numerous observations of Wright gave symptoms almost constantly identical; dilated pupils, convulsions, rapid pulse, staggering, paraplegia, prostration, coldness of the surface, death. The prolonged exhibition of ergot produced analogous phenomena, differing only in degree of intensity.

[To be continued.]

#### A CASE OF HERPES ZOSTER OPHTHALMICUS, IN A PATIENT 80 YEARS OF AGE, CAUSING FATAL PROSTRATION; WITH REMARKS.

By B. JOY JEFFRIES, A.M., M.D., Ophthalmic Surgeon  
Mass. Char. Eye and Ear Infirmary, Boston, &c. &c.

(Continued from page 292.)

I THINK, very naturally, medical gentlemen may be inclined to doubt the correctness of my diagnosis in this case, or perhaps even the existence of so curious and sometimes so formidable a disease. I shall, therefore, in support of my views, take the liberty of here quoting gentlemen whose opinion and observation will be unquestioned. Mr. Jonathan Hutchinson, in the Royal London Ophthalmic Hospital Reports, says, of herpes zoster affecting one or all the branches of the ophthalmic nerve: "This most interesting-disease has as yet received but little attention from writers on skin diseases, and, as far as I am aware, scarcely any from ophthalmic surgeons." "The disease is, I am persuaded, more frequent than is generally supposed. In proof of this I may mention that, during the last year, no fewer than three patients have consulted me in private on account of its effects. I have found most surgeons very incredulous as to this disease, and free in asserting that they had never seen it, and that it must be extremely rare. My conviction is that it is often misnamed. It is often considered to be erysipelas. Three patients who came to me with the unmistakable marks of herpes on one side of the forehead had been treated for a disease which had been said to be erysipelas, and several others in my series had also had a similar diagnosis given. Yet it is easy enough to distinguish the one from the other, if attention be once drawn to their differences. Herpes frontalis is always limited to one side—never transgresses the median line of the forehead and nose. It never affects the cheek, although there may

be some sympathetic œdema of the part (œdema of contiguity). There is less general swelling of the skin than in erysipelas, and in some cases very little.' The vesicles of herpes are smaller, more defined, more numerous, and altogether much more conspicuous and pronounced than are the bullæ of erysipelas. There is much more pain and much less constitutional disturbance in herpes than in erysipelas. The strictly unilateral character of the one, contrasted with the irregular location of the other, is, however, the most reliable feature for the purpose of ready diagnosis." "Herpes almost invariably leaves scars, often deep ones, and by the arrangement of these (unilateral) it is usually easy to recognize a patient who has suffered from the disease, even years after its occurrence." In proof of this latter we would refer to a photograph and wood-cut in the Ophthalmic Hospital Reports given by Mr. Bowman, who there says in regard to ophthalmic shingles: "Cases of this nature have attracted my attention during many past years." "I have frequently seen this disease mistakenly called 'erysipelas,' even by accomplished practitioners. From this it is distinguished by the pain preceding the symptom, by the mingled numbness, pain, and heightened sensibility remaining for a long period after the inflammatory outburst, and especially by its not overpassing the median line." To show that these views are supported by absolute observations, I will here introduce a tabulated statement [see next page] of twenty cases of this form of zoster, collected by Mr. Hutchinson, and thirteen cases reported by Mr. Bowman, all occurring within the last few years. They certainly would seem to show that the complaint is not so very infrequent, and would be oftener noticed were it always diagnosed.

About a month after I had reported my case and read this paper at the Newport meeting of the American Ophthalmological Society, 1868, the subject of herpes zoster ophthalmicus was introduced at the Heidelberg Ophthalmological Society by Dr. Steffan, of Frankfurt. The report is so interesting that I here introduce what was said, translated from the proceedings of the society published in Zehender's *Klin. Monatsbl. f. Augenheilkunde*. Dr. Steffan: Frankfurt.

"Allow me to call attention to the very interesting disease known as *herpes zoster frontalis, seu ophthalmicus*, which from ophthalmologists has been but lately properly noticed, by our English colleague Hutchinson. Since his remarks in the 5th

vol. of the Oph. Hosp. Reports and Bowman's in the 6th vol., I do not know of any notice of herpes zost. front. in the French and German ophthalmic journals; and therefore, as also in consequence of the rarity of the disease, I think the following in place here. I had for the first time a case under my care the past summer.

An operative, æt. 36, who had always been well, applied to me with an already fully developed cutaneous eruption, the history of which before and after his appearance only completely confirmed the correctness of Hutchinson's observations. (Dr. Steffan then exhibited to the Society a photograph of this patient, taken after the disease had run its course, together with the photograph of Bowman's case, from the Oph. Hosp. Reports, and proceeded with the following description of the disease.)

The patient suffers for several days, even up to the ninth, the most intense neuralgic pain in the brow and head. Then a cutaneous eruption appears, i. e. the skin swells and becomes red. In some cases, firm, resisting spots are perceptible in the subcutaneous cellular tissue; afterwards, fine vesicles appear on the surface of the skin, in groups or plaques. The separate groups of vesicles become confluent, the contents, consisting of mixed blood and pus, dry up to a thick scab, and when these fall off deep scars are left, which last the patient's life-time, and remain a perfect proof of the disease having existed. From the announcement of the cutaneous eruption to its end, i. e. the formation of scars, is about three weeks. Even after the scars have formed, the neuralgic pain may continue in the parts affected in the most aggravated form, whilst the cutaneous surface itself feels numb and parchment like. The locality of the affection is distinctly marked out, that is, it affects only the portion of skin supplied by the first or ophthalmic branch of the trigeminal nerve—the forehead, upper lid, and nose to its tip. As we know, the first branch of the trigeminal divides at the fissura orbitalis superior, or before this, into three nerves—lacrimalis, frontalis and naso-ciliaris. The lacrymalis goes to the lacrymal gland and the neighboring skin of the upper lid. The frontalis, dividing into supra-orbitalis and supra-trochlearis, goes to the brow. The naso-ciliaris, which in connection with this disease mostly interests us ophthalmologists, gives off a *radix longa* to the ciliary ganglion, and some *nervi ciliares longi*, and then divides into the *infra-trochlearis* and ethmoidalis. The *infra-trochlearis* passes

MR. HUTCHINSON'S TABULAR STATEMENT OF 20 CASES OF HERPES ZOSTER FRONTALIS, SEU OPHTHALMICUS.—*Oph. Hosp. Rep.*, Vol. v., Parts 3, 4.

No.	Name—Date—Reference.	Health, premonitory symptoms, &c.	Parts affected.	Nerve affected.	Remarks.
1	Geo. Morgan, Ophthalmic Hospital, Sept. 9, 1861.	Florid; nearly bald.	Left forehead, upper eyelid, iris, side of nose to tip.	Whole ophthalmic division of fifth.	The eye inflamed, and was practically lost.
2	Mrs. Kimpter, Metropolitan Free Hospital, Dec. 17, 1861.	Very pale and feeble.	Left frontal region and mid region of side of nose.	Frontal and both trochlear branches.	Eye not inflamed.
3	William Woolgar, March 29, 1862.	In usual health.	Right forehead and mid region of side of nose.	" "	Eye not inflamed. Portrait by New Sydenham Society.
4	Joseph Bond, July, 1859.	Subject to broucheitis.	Left forehead.	Frontal division only.	Eye not inflamed. Shingles, also, at same time, right side of the chest.
5	A. B. Clerk, Ophthalmic Hospital.	In good health; ten days' premonitory pain, severe.	Left forehead.	" "	Eye not inflamed.
6	Mrs. Barnes, Ophthalmic Hospital, June 9, 1853.	Pale and thin, but in good health; severe headache preceded, but not continued to the forehead.	Right forehead.	" "	Not very severe case. Eye not affected at date of notes. No subsequent record.
7	J. Thomas, Ophthalmic Hospital, April, 1865.	Healthy sailor.	Forehead and side of nose.	Frontal, trochlear and oculo-nasal branches.	Notes imperfect, and do not state more than that there was not much mucous discharge from the eye.
8	J. Anderson, Ophthalmic Hospital, June, 1866.	Tailor, in good health. Had pain in part, and slight rigor the day before eruption came out.	Left forehead, side of nose, iris, cornea, &c.	" "	Extensive opacities of cornea and posterior synechia. Pupil did not dilate to atropine.
9	Mrs. B., of Sutton, Bedfordshire.	A spare, but healthy lady.	Left forehead, side of nose, cornea, conjunctiva and iris.	" "	Patient came month after attack, on account of the damage to the eye.
10	Mrs. M. Hertford.	A lady in rather feeble health, and with suspected renal disease.	Forehead, conjunctiva, side of nose, cornea and iris.	" "	Patient came, as last case, on account of eye. Cornea hazy, pupil fixed, skin numb.
11	Mr. — Hackney.	A very healthy man.	Left forehead, side of nose, conjunctiva and cornea.	" "	Sent me on account of cataracts.
12	Dr. Markham.	46? Good health.	Left forehead and side of scalp.	Frontal; eye did not inflame.	This accomplished physician was himself the patient.
13	A girl, London Hospital, Dr. Parker's case.	. . . . .	Left forehead, side of nose and iris.	Frontal, trochlear and oculo-nasal branches.	Shown me by Dr. Woodman.
14	Danielsen and Boeck's, Atlas of Skin Diseases.	65? Good health.	Right forehead and side of scalp.	Frontal.	No inflammation of the eye.
15	Hayes's case, Man.	47? . . . . .	Left forehead.	Frontal division.	Eye not mentioned.
16	Dr. Broadbent, patient an officer.	23 Spare, but in good health.	Right forehead and side of nose, but not to tip.	Frontal and both trochlear branches.	The eye inflamed, and the cornea was slightly opaque.
17	A girl.	12 . . . . .	Forehead.	Frontal.	Eye not inflamed.
18	Mrs. —, Ophthalmic Hospital.	60 Good health.	Right forehead and side of nose.	Frontal, trochlear and oculo-nasal branches.	The side of the nose chiefly affected. Complete blindness resulted.
19	Mr. Parker, Ophthalmic Hospital.	14 Strumous looking.	Left forehead, scalp and upper lid.	Frontal.	Mild course. No inflammation of the eye.
20	A. B. case of Mrs. Ransom, Bowd.	43 Good health.	Left forehead.	Frontal.	No vesicles on nose, and no inflammation of eye.
	A. B.	80 (My own case. B. J. J.). Good health.	Left forehead, scalp, lid, side of nose, eye.	All branches of ophthalmic.	Disease ran its course in 36 days; patient died from exhaustion on the 44th day.

No.	Name—Reference.	Age	Health, premonitory symptoms, &c.	Parts affected.	Nerve affected.	Remarks.—Complications.
1	Miss B., Oct., 1855.	40	. . . . .	Right forehead.	Frontal.	Ophthalmia and cornelitis in right eye, leaving nebula.
2	Miss H., 1860.	57	Had had inflammation of o. d.	Right forehead.	Frontal.	Cornelitis and iritis in right eye, leaving dense nebula.
3	Mr. W., 1858.	36	. . . . .	Left forehead.	Frontal.	Internal strabismus left eye; diplopia.
4	Mr. L., July, 1865.	70	Has had diplopia.	Left forehead and scalp.	Frontal.	Conjunctivitis. Supra-orbital nerve divided; no permanent benefit.
5	Mr. S., Jan., 1864.	41	. . . . .	Left cheek and temporal region.	Submaxillary and frontal.	Atrophy of optic nerve, left eye.
6	Sam H., Nov., 1864.	55	. . . . .	Left side of head, cheek, nose and lids.	Frontal and nasal.	Cornelitis leaving nebula, left eye. Supra-orbital and infra-trochlear divided; considerable relief.
7	Miss S., 1861.	60	. . . . .	Forehead, right.	Frontal.	Nebulous cornea, right eye.
8	Mrs. S., Sept., 1866.	52	. . . . .	Right forehead and infra-orbital region.	Supra-orbital and infra-trochlear.	Ulcers of cornea, iritis, right eye.
9	Ed. H., Nov., 1866.	70	. . . . .	Right forehead, temple and upper lid.	Frontal.	Thickening of lid, globe not affected.
10	Jos. Haynes, 1867.	4	. . . . .	Left forehead.	Frontal.	No affection of the eye.
11	Thos. Redburn, 1865.	9	. . . . .	Right forehead and upper part of nose.	Frontal and nasal.	Leucoma, right cornea (due to herpes?).
12	A. Turnbull, 1867.	12	. . . . .	Forehead (right?).	Frontal.	No vesicles on nose; eye not inflamed.
13	Anne Robins, 1867.	44	. . . . .	Right forehead.	Frontal.	" " " " " "

over the ligamentum palpebrale internum to the orbit, and in connection here with the supra-trochlearis spreads upon the upper lid and the skin of the root of the nose. The ethmoidalis passes through the ethmoid opening transversely inwards to the inside of the skull, and then forwards on the lamina cribosa of the ethmoid bone, through the anterior foramen cribosum near the crista galli into the nostril, there dividing into three twigs, one of which comes out on to the skin of the top of the nose from between the under edge of the nasal bone and the cartilage. The cutaneous eruption in herpes zoster ophthalmicus affects in but a very small number of cases the whole cutaneous district of the first trigeminal branch. It always affects the distribution of the supra-orbitalis and mostly that of the supra-trochlearis; the former may be affected without the latter, the latter never, however, without the former. The eye does not suffer when the frontal distribution of the first trigeminal branch is alone affected. It is only in danger of being involved when, besides the frontal branch, the naso-ciliaris is also affected—i. e. the cutaneous eruption appears on the side and tip of the nose. In my case, the cutaneous eruption was on the forehead, upper lid and side of the nose down to the tip, and yet the eye escaped—a proof that ocular trouble is not necessarily associated with the affection of the skin of the nose. In the 24 cases grouped by Hutchinson (15 men and 9 women), the side of the nose was only affected 9 times; and in these 9 cases the cornea and iris were affected but 6 times. The participation of the eye is, according to Hutchinson, expressed in two ways—either as ulcer of the cornea or as iritis, with all the consequences of these diseases, even to loss of the visual organ.

In commencing, I spoke of the rarity of this complaint as the cause of its being so little known. There is, however, another reason for this, namely, its being mistaken for erysipelas of the face, as occurred in my case by the physician under whose care the patient first came. The two diseases are, however, very different. Herpes zoster frontalis never passes the median line of the face, and is strictly confined to the distribution of the first branch of the trigeminal in the skin of the brow, upper lid and nose, leaving the cheek and lower lid free. The products of herpes zoster frontalis are numerous fine vesicles grouped in masses (*plaques*), which afterwards run together, but never form single large blebs as in erysipelas. Herpes zoster frontalis is accompanied with very great local pain,

preceding the cutaneous eruption several days; moreover, we do not have the severe febrile action, indicating participation of the whole system in the disease, as is generally the case in erysipelas. Herpes zoster frontalis leaves scars on the skin, and often deep ones, which, from their being located over the distribution of the affected nerves, ever afterwards mark the occurrence of the disease, whilst, on the other hand, no traces are left by erysipelas. Herpes zoster frontalis attacks the patient but once, and does not threaten his life, the reverse of erysipelas of the face. The eye is in great danger in herpes zoster frontalis; not so, however, in erysipelas.

Finally, if we seek the essence of herpes zoster frontalis, there can be no doubt that the immediate cause of the disease must be looked for in the peripheral distribution of the cutaneous nerve from the first trigeminal branch. This follows from the fact that extreme pain in this nervous district precedes a long time every symptom on the skin. There is nothing by which we might refer the disease to the central nervous system, or suppose it to arise by reflex nervous action. Whether the peripheral distribution of the sensitive cutaneous nerves, or the vaso-motor (trophic?) running in the same district, are the originators of the disease, must at present still remain a question.

Herpes zoster frontalis is distinguished from all other forms of zoster by two characteristics. First, that the cutaneous eruption develops to deep pustules, leaving scars after the process has run its course; and second, that before the appearance of the eruption and after it has dried up, there are such severe neuralgic pains as to render the disease a severely painful one. For ophthalmology, however, herpes zoster frontalis has a special meaning, from the participation of the naso-ciliary nerve and the concomitant ophthalmic affection. Our English colleague Hutchinson deserves the credit of having brought this last point to especial notice, and thereby connected herpes zoster frontalis seu ophthalmicus with ophthalmology.

#### DISCUSSION.

Dr. Kreitmair, of Nuremberg.—I can add nothing to the description of herpes zoster which we have heard, it is complete and accurate, and would only say that I had two cases occurring within a short time of each other, one a strong, well-built workman, with whom I saw the zoster commence. He applied to me with a swelling, complaining of such fearful pain that, from

a man of his condition, was something new for me to hear. On the second and third days the pustules appeared in the described form of herpes zoster. The second case was that of a young girl about 15 years of age. These two cases occurred close together, at a time when neuralgic affections were almost epidemic in Nuremberg. I often had to control the neuralgia with quinine; the zoster was treated in the same way, and I may assert that it seemed to be limited thereby. In one case very visible deep scars were left.

Dr. Horner, of Zurich.—I may be allowed to add that I saw a case of zoster, in iritis, where the disease was not present on the side of the nose, so that the participation of the naso-ciliary branch was by no means so strikingly exhibited. I was called to the patient on account of the iritis. The appearances of herpes zoster were, however, perfectly marked, namely, the grouping of the vesicles and the secondary formation of bullæ.

Dr. Kreitmair, of Nuremberg.—I may add that in my two cases the globe remained intact.

Dr. Pagenstecher, of Wiesbaden.—If any one is interested in studying the scars they may see them on me, as I went through with the disease. It was in my last term as student in Würzburg, and I was not then, of course, so interested in the disease. I, however, remember the course of it perfectly well. It was just as Dr. Steffan has described it, only the prodromous stage was not so long. Some two days previously, I had a numb feeling over the distribution of the ophthalmic branch, and immediately before the eruption a very severe itching, with considerable swelling of the lymphatic glands on the whole right side down to the neck, so much so that leeches were ordered by the attending physician, Dr. Markus, since dead. Finally, the appearance of the eruption left no doubt as to its being herpes zoster. My eye was severely affected, I had keratitis but no iritis, and the whole course was quite rapid, so that by the eighth day the crusts fell off, leaving scars now nearly obliterated. I had no subsequent neuralgic troubles.

Dr. Laubsberg, of Görlitz.—I desire only to call attention to the admirable action of hypodermic injection of morphine, which certainly exceeds that of quinine and all other remedies. It is not simply momentary or symptomatic, but can mitigate, at least, the pain and intensity of the attacks for some days.

I have not hunted through the journals

for reports of individual cases, as I thought the above, occurring within the last few years, were sufficient at least to identify the disease and prove the correctness of my diagnosis. However, to show that cases are occurring repeatedly, and are properly diagnosed and reported, I introduce the two following. The first is by Dr. Johnen, in the September appendix to the *Vienna Medical Newspaper*.

A woman, æt. 38, healthy, had for four days pain about the left eye, and in the eye itself, perfectly simulating neuralgia. So great photophobia that the patient kept the eye covered with a cloth. The upper lid was swollen; the conjunctiva of the lid and globe reddened and lax; the pupil contracted and the iris discolored. Iritis was the only diagnosis that could be made, and therefore atropine collyrium was ordered, with proper care of the eye, and general treatment. On the third day there were groups of herpes on the forehead to the median line, on the temple to the edge of the hair; a long group on the nose, reaching from the inner canthus to where the nasal cartilage commences. The upper lid was so œdematous that the globe could hardly be exposed; the conjunctivæ were reddened and swollen; the whole cornea steamy, a phlyctenula directly in the centre; the eye still very sensitive to light, although the pupil is somewhat dilated. The patient has very little fever, although the constant pain has destroyed all appetite, and she is scarcely able to attend to her housework. The herpetic vesicles ran through their ordinary course. The corneal vesicles flattened and changed into an open ulcer, which healed but slowly, and left an opacity. The iritis disappeared without deposit. Besides atropine, treatment consisted of subcutaneous injections of morphine. Whilst the former dilated the pupil, the latter seemed to have no effect on the pain. A glance at the anatomy of the trigeminus shows that the zoster spread exactly in the course of the ophthalmic branch. Whether the cartilaginous portion of the nose, in the skin of which a branch of the ethmoid is distributed, escaped accidentally, like other clear portions of the skin between the vesicles, or from anatomical relations, the observer would not decide. He regarded the affection of the iris and cornea as part of the herpetic process, and not as caused by the stasis in the conjunctival vessels. The iritis was the first visible local expression of the disease, and already present before the inflammatory action of the other portions of the globe reached its height. The

VOL. III.—No. 18A

want of action of atropine, mentioned by Hutchinson, does not appear to be due to any specific action of the zoster, but dependent on the extreme inflammatory vascular injection as so often observed in iritis from whatever cause. In this case atropine had its usual effect. The observer regards the term herpes zoster *ophthalmicus* as more appropriate for this affection than herpes zoster *frontalis*.

Dr. Ringer, *Lancet*, Sept. 19, 1869, University College Hospital, reports the second:

The patient a lad of 17. The eruption was confined to the integument supplied by the ophthalmic and superior maxillary branches of the fifth, the part supplied by the inferior maxillary being unaffected. The eruption was on the left side, strictly limited by the median line, and affected the anterior part of the hairy scalp, the forehead, and upper part of the face and side of the nose, being bounded below by the mouth and a line drawn from the angle of the mouth to the malar bone, an inch and a half in front of the ear. The eyelids were œdematous and the conjunctivæ inflamed. Thus it corresponded closely to the cutaneous distribution of the supra-trochlear and supra-orbital and nasal of the ophthalmic, and of the orbital (temporal and malar) and infra-orbital branches of the superior maxillary.

I shall not here attempt to solve the nosological riddle presented to us by herpes zoster in general, but would refer to the monographs, &c., in the list at the end of this article. In these, others still are referred to, which will carry any one desirous of pursuing it, through the whole literature of this interesting subject. Special mention should be made of Mr. Bowater J. Vernon's report of five cases of herpes zoster ophthalmicus in the *St. Bartholomew's Hospital Report*, vol. iv. 1868.

Prof. Baresprung published in the *Annals of the Charity Hospital at Berlin* a series of articles on zoster, with reports of cases in 1861-63. His suggestions have lately been quoted and acted upon as if they were settled opinions, the very errors in diagnosis which he warned against fallen into, and his carefully observed facts treated with such nonchalance, that I think it but justice to him to translate the following passages from the original articles.\* Under the etiology of zoster Prof. Baresprung says:—

"Physiological facts have long ago proved beyond doubt, that the cerebro-spinal nerves

\* I refer to the article on zoster and the reported cases in Dr. H. F. Damon's little work on *Neuroses of the Skin*.

carry, besides the sensitive and motor, a third set of fibres of a different character, coming from the sympathetic system, and these alone must be thought of as the peculiar medium of trophic action. At all points where there are ganglia, such fibres enter the nervous cords, since they spring from the ganglion cells themselves. It is, however, the peculiar province of every large ganglion to supply certain organs with trophic fibres. Where, however, do those arise which go to the surface of the body, whose morbid irritation calls forth the curious phenomena of the rupture of zoster? We have already shown where they must arise; everything points to the posterior roots of the spinal nerves, each of which is furnished with a ganglion. The spinal ganglia give us the key to the solution of all the appearances.

According to Kölliker's observations, the sensitive nerve-fibres of the posterior roots pass through the spinal ganglia without forming connection with them; whilst the ganglionic fibres coming from the ganglia themselves never spread towards the spinal cord, but all take the peripheric course of the sensitive fibres. Close to the ganglion the motor fibres of the anterior root join, and thus form the short stem of the spinal nerves. This soon divides again into an anterior and posterior branch, each of which takes sensitive, motor and ganglionic fibres, and passes to the surface of the body.

I know very well that the difficulty of ascertaining this histologically throws many doubts upon its admissibility, and that some physiological experiments seem to speak against it, but the clinical facts appear to me to here offer absolute proofs. If this is so, and in reality the trophic action in the skin is brought about through the nerve-fibres coming from the spinal ganglia, then all cases of fully developed zoster and all cases of zoster running their course without other nervous disturbance, are to be referred to irritation of these ganglia themselves, as from them alone the trophic elements spring. In the course of the nerves these latter are so mixed with the sensitive and motor, that it is not conceivable how any cause can act to excite them alone.

The neuralgic pain attending zoster is explained by the transmission of the irritation from the ganglion to the special posterior root, and thus the latter may spread its excited condition by means of the spinal cord to neighboring or symmetrical nervous districts, whilst the trophic irritation remains unilateral, because the ganglion

sends no fibres to or receives any from the spinal cord.

Besides the district, however, of the spinal nerves, we have seen zoster appearing in the course of the trigeminal, a cerebral nerve completely analogous to the spinal nerves in that its sensitive root is also provided with a ganglion close to its origin. The Gasserian ganglion here acts the part of the spinal ganglion, and on it seems to depend the trophic functions in the skin of the face."

Only two *post-mortem* examinations of patients with zoster had been reported, which Baresprung gives. One, by Rayer, afforded no result; the other, by Danielssen, showed *neuritis intercostalis*. The spinal ganglia, however, were not examined. Baresprung afterwards had opportunity of making one, the result of which is so interesting as to give it place here.

In September, a child one year old was taken into the hospital on account of scrofula, the glands of the neck and over the sternum greatly swollen, a bronchial catarrh and considerable emaciation. In the following May, without apparent cause, zoster appeared on the right side, in the form of a band more than two inches wide between the 6th and 9th ribs, behind spreading a line or two over the median line, from the 6th to the 8th vertebrae, and terminating in front under the xiphoid process. This zona ran through its course, and the tuberculosis increasing and attacking the lungs, the child died, emaciated, on the 21st day. *Post-mortem* examination showed the signs of tubercle in the lungs and lymphatic glands. Upon very careful examination, the spinal cord was found unaltered. The anterior and posterior roots, from their origin in the cord to their entrance in the intervertebral openings, quite white and evenly firm. On opening the intervertebral canal and exposing the 5th to 9th intercostal nerve, great thickening and reddening of the 6th, 7th and 8th was noticed, especially the 7th, apparently due to a swelling of the neurilemma permeated with tortuous vessels. The 7th intercostal nerve was half as thick again as the 5th or 9th, these latter remaining quite white and unaffected; this enlargement reached about an inch on the anterior and not so plainly on the posterior branch; further on, the intercostal branch appeared quite normal and white. The 6th and 8th exhibited this redness and swelling, but not so markedly or for so long a distance as the 7th. The spinal ganglia belonging to these three nerves were more

firmly adherent on the wall of the intervertebral canal; the connective tissue here also more red and thickened, so that the ganglia seemed to have increased in volume. These differences were still plainer after the nerves, with the ganglia, had been dissected out and put in water, the coating of connective tissue not floating readily, as it was thickened; letting the light pass through showed the ganglia and the nerves coming from them of a dark-rosey red, this color being in the neurilemma and not in their substance. The microscope showed also undoubted remains of inflammation, principally, it is true, in the neurilemma; a fine granular mass was found in the external covering of the ganglia, as also between the minute lobes, partly irregularly strewn, partly massed in roundish groups and lumps, the brownish color of which would indicate escaped and broken-down blood-corpuscles; the connective tissue in which they lay was apparently richer in granules, less elastic and looser than the rest. These changes reached beyond the ganglion to the point of crossing, and to the two branches as far as they appeared externally reddened, gradually lost themselves, so as not to be seen in the distant part of the nerve. There was no peculiar alteration of the nerve-substance to be seen, either in the ganglion or in the nervous bundles, and yet here and there where the granular masses were most grouped the fibres were altered in form, varicose, coarsely granular, and even their continuity interrupted. Barendsprung gives plates of the microscopic drawing of these appearances, and he adds:—"The *post-mortem* has shown what was to have been expected, that there is not in zoster a destructive process, but only a slight and readily reparative one. It has, moreover, shown very clearly that the disease originates in the spinal ganglia. In this connection, it seems to me to be of special interest that the inflammation extended peripherically outwards from the ganglion, and not through the posterior root to the spinal cord. If, as the microscope would seem to show, there is only inflammation of the neurilemma, then the inflammation would have spread in both directions, whilst its simply peripheric extension much rather points to conduction through the ganglionic fibres arising from the ganglia."

"To recapitulate: zoster depends on a disease of the ganglionic system, and in special cases on irritation of some of the spinal ganglia or the Gasserian; yet the peripheric irritation of a nerve having gangli-

onic fibres in it may be followed by a limited eruption of zoster vesicles. By this it is not at all meant that further *post-mortem* examinations must necessarily show always coarse structural alterations in the ganglia. The pathology of the diseases of the brain and spinal cord prove how often any anatomical grounds for many disturbed nervous actions escape the best armed eyes."

Now, aside from any theory drawn from it, this observation of Barendsprung is certainly very important and interesting, sufficiently so to be quoted in full by Proust in an article on the "*Troubles of Nutrition consequent on Affections of the Nerves*," published in the *Archives Générales* for February, 1869. In connection with it, Proust quotes another case of Charcot's, which he says gives it a new interest. A woman, aged 78, entered Salpêtrière Jan. 16, 1865, with cancer of the right breast, not ulcerating. About the 15th of December, an eruption of zona appeared over all the right half of the neck, behind, on the side, and in front, not passing the median line either before or behind. The perfectly characteristic groups of herpetic vesicles were pretty uniformly distributed and numerous on the nape and above the clavicle; some were scattered over the top of the shoulder, the lowest part of the cheek and the mastoid region, and finally on the infraclavicular region to the upper edge of the pectoralis major. It is seen that the eruption occupied all the portion of the skin supplied by the branches of the cervical plexus of the right side. The autopsy showed nothing in the cord. The intervertebral canals were open, which was verified; the anterior and posterior roots, both right and left, had preserved their volume and color; on the right side, the spinal ganglia, as well as the nervous trunks formed by the union of the spinal roots, presented a slight tumefaction and vascular injection, as shown by the deep red color. Outside of the openings, the red color of the nerves gradually faded, and was no longer visible on the nervous fibres coming from the cervical plexus. Microscopic examination of the ganglia and the red and swollen nervous trunks showed the following:—In the ganglia the nerve-cells presented no appreciable alteration; they contained a large quantity of dark pigmented granulations, but these existed nearly in the same number and of the same character in the ganglionic corpuscles of the left side. The vascular plexus of the ganglia was vividly injected, and the addition of acetic acid brought out nuclei more nume-

rons than normal in the laminous texture. In the nerve-trunks there was marked ingestion of capillary vessels of the neurilemma, and acetic acid brought out very abundant nuclei. The nerve-tubes retained their physiological character and condition. (Vide Charcot et Cotard, *Mémoires de la Société de Biologie*, 1866, p. 41.)

(To be continued.)

## Bibliographical Notices.

*A Treatise on the Diseases of the Eye.* By J. SOELBERG WELLS. Philadelphia. 8vo. Pp. 739.

THE literature of ophthalmic science seems in no way likely to suffer from want of earnest and frequent contributors. No other branch of medicine has made such great progress during the past twenty years, and the rapid increase of its literature is the natural consequence of its remarkable advance.

For many years the original work of Mackenzie was the standard authority, and although we have on most points left it far in the rear, yet in some respects it stands on the same ground as its more modern brethren. Lately it has been thoroughly revised and brought up to the modern mark in French by MM. Warlomont and Testelin.

Recently several excellent treatises on the eye have appeared, among which may be mentioned in particular those of Stellwag von Carion and Wecker. Stellwag von Carion's (Am. translation from 3d German ed.) is a very valuable work, embracing the whole subject, but the style of the translation is frequently faulty and heavy, and the author's meaning at times difficult to appreciate, especially on the subjects of accommodation and refraction. It will always be useful, however, as a work of reference to the specialist, but can hardly find a place as a text-book for students or avail much to the general practitioner. The work of Wecker, which has now passed through two editions, is undoubtedly the clearest and most complete that has yet appeared, but its size, cost, and the fact that it is not in our own tongue, will prevent many from obtaining it. Besides these there are the works of Bader, Powers, Macnamara and others, as well as many monographs and a large amount of journal literature on special departments of the subject.

With such a formidable array of authors

already in the field, it would at first sight seem that there was no occasion for another treatise on the diseases of the eye. This, however, is not the case. Mr. Wells's work will be found not only highly useful to the specialist, but will fill a want long felt by the general practitioner and student, in offering them a comprehensive and clear description of the subjects of which it treats.

Mr. Wells has appeared already as a writer of numerous articles connected with his specialty, and a small treatise on "Impaired Vision," in which he displayed a happy faculty of simplifying and condensing the difficult subjects of accommodation and refraction. The same clearness and conciseness of expression characterize the present work almost throughout the volume.

The arrangement of the *matériel*, which differs from that of any other author, is not objectionable, though we prefer that of Wecker as more natural anatomically. The minute anatomy and the pathology of the subject are not given as distinct parts of the work, but only so much as is necessarily involved in the description of each disease, and then in rather limited amount.

The book opens, as is usual, with remarks about bandaging, manipulation, &c. The chapter on conjunctival diseases is well written, the descriptions of the various affections graphic, and the treatment up to the best modern standard. The author thinks "that the term 'simple conjunctivitis' should be altogether discarded. It is in fact only the mildest form of catarrhal ophthalmia, and hence there is no reason to make it a distinct form of disease." Of purulent ophthalmia he says, it may "be regarded as a more severe form of catarrhal ophthalmia, in which all the symptoms of this affection are intensified in degree." Indeed, it has been proved by experimental observation, that the different forms of conjunctivitis are allied in type, if varied in the degree of their severity, and that the secretion of any form of the disease is capable within certain limits of producing in sound eyes almost any of the other forms. The use of the acetate of lead, either as a wash, as advised by the author, or in the heroic manner adopted in Belgium, is to be deprecated, since with the slightest abrasion of the cornea an opaque deposit, difficult and at times dangerous to remove, is the result.

The treatment of diseases of the cornea is excellently given, though we must differ from Mr. Wells in the propriety of puncturing the bottom of an ulcer threatening

to perforate. The very objects for which paracentesis corneæ is done, viz., to prevent perforation, synchia and harm to the capsule of the lens are seriously endangered by this procedure. The old method of paracentesis at the periphery of the cornea certainly appears far safer, until better reasons are offered for the substitution of another. With regard to diffuse or interstitial corneitis he very justly says, "I cannot at all agree with the view that diffuse corneitis is always due to inherited syphilis, for although I have often seen it associated with the latter, yet in many cases not the slightest trace of a syphilitic taint could be ascertained, and there was a marked and complete absence of the peculiar syphilitic features and the notched teeth."

In the treatment of non-specific iritis, where there is considerable tendency to the exudation of pus or lymph at the edge of the pupil, mercurial inunction is strongly advocated—a practice which has not obtained here of late. The operation of iridodesis (Critchett's), but rarely done in this country, is urged, and with apparently good reason, for artificial pupil in lamellar cataract, conical cornea and leucoma corneæ. The subject of cataract and the operations therefor are well and thoroughly discussed, the preference among the latter being given to Von Graefe's modified linear extraction—and, judging from the results of this operation, now practised for some three years, it has surpassed every other form of extraction.

The portions of the book devoted to the retina, optic nerve, amblyopia and amaurosis are written with admirable clearness, and give the latest researches of English and continental authorities on these subjects. The chapter on glaucoma is a succinct and thorough exposition of the history, diagnosis and treatment of this much-written-about disease, and is decidedly the best resumé of the subject that we have in our language.

In the more purely scientific parts of the work Mr. Wells is as successful as in the descriptive portions, and the use and theory of the ophthalmoscope and the anomalies of refraction and accommodation are treated in a manner which will render them plain to any reader acquainted with the science of optics, even in a slight degree.

The remainder of the book is taken up by the consideration of the affections of the extrinsic muscles of the eye, lachrymal apparatus, orbit and eyelids, and is equally worthy of careful reading with the previous

portions, especially the chapter on the first of the subjects just mentioned.

As a whole, the book is remarkably well written, in a distinct and agreeable style, though we are surprised to find an English author coining such words as "diagnose" and "microscopizing." It is beautifully printed on good firm paper, and has a number of woodcuts and diagrams. The plates are chromolithographs copied from Liebreich's Atlas, and are good reproductions of illustrations of the morbid appearances of the eye, which have not yet been surpassed, and indeed, hardly equalled.

The dedication is to Von Graefe, and from the frequent occurrence of that distinguished oculist's name, as well as other German authorities, throughout the volume, it must be regarded as rather a German than an English work—in all save the language. But this is unavoidable, for the Germans have been the originators of almost all the great modern advances in the therapeutics and surgery of the eye. Still, if the author cannot lay claim to much originality, he is at least entitled to great praise for having performed his work with excellent judgment, in a manner at once conscientious, thorough and agreeable.

R. W.

## Medical and Surgical Journal.

---

BOSTON: THURSDAY, JUNE 3, 1869.

---

DR. D. F. LINCOLN discontinues his connection with the JOURNAL, as it is difficult for him, with his other avocations, to give his attendance at the office. We are still, however, to have the benefit of his German scholarship in the supply of translated extracts from German periodicals. Those extracts will be designated by his initials, as heretofore.

Dr. II. H. A. BEACH has, for the present, kindly consented to discharge certain duties on behalf of the Editor. It is somewhat uncertain whether Dr. Beach will be able to continue his valuable aid to us after the lectures commence at the Medical College, where he is engaged as Assistant Demonstrator.

MR. EDITOR,—By request of Prof. Freer, who is now on his way to Europe, I send

you, by mail, the *Chicago Medical Journal*, containing an article on the "Discovery of a new Anatomical Feature in Human Blood Corpuscles"; also, by express, the electrotype plates of the diagrams illustrating the same, hoping that you may deem the discovery there set forth of sufficient importance to re-print the article in your valuable JOURNAL.

This article will, in due time, be followed by others, which will be promptly forwarded to you if you so elect. \* \* \* \*

Yours truly,

F. L. WADSWORTH, M.D.,

For Prof. J. W. FREER, *Chicago, Ill.*

We would express our profound appreciation of the favor done us by Prof. Freer, in enabling us to use his valuable contribution to histological investigation.

In the *Chicago Medical Journal* of May 15th, 1868, Vol. XXV., No. 10, in a brief, hastily written article, I announced that I had, as I believed, discovered that human blood corpuscles "are not, as heretofore supposed, simply bi-concave discs; but, on the contrary, there may be seen (by the use of Wale's illuminator), a nipple-like eminence in the centre of the concavity of each well-formed disc. This papillary eminence is about one ten thousandth ( $\frac{1}{10000}$ ) of an inch in diameter at its base. That it is a true anatomical form, and not a change incidental to desiccation, &c., is shown by its appearance at the instant of withdrawal of any given specimen, while the corpuscles are still plump and smooth in all other respects."

Continued investigation on this important subject has served only to confirm the announcement then made; and having had the opportunity of exhibiting corpuscles as herein described, to several eminent men of acknowledged scientific ability, and having received their opinion in corroboration of my own, I propose to set forth in this paper the views heretofore entertained upon this subject, and in contradistinction present my own more fully, illustrated by accompanying diagrams, which were drawn by an artist who had never before seen blood corpuscles, and, consequently, to be taken as unprejudiced testimony.

Among physiologists and microscopic anatomists there has been but one generally expressed opinion as set forth in standard works, illustrated and otherwise; *to wit*, that the human blood corpuscle is non-nucleated.

It may appear incautious, and even rash, to array one's self against evidence so

weighty, but my convictions have ripened under careful and persistent investigation, and I deem the announcement timely and worthy of earnest attention.

It may be superfluous to quote the opinions of authors with whom nearly all are familiar, but for a concise presentation of the subject I deem it advisable.

Prof. F. here refers to Todd and Bowman, Wharton Jones, Mueller, and Kölliker as holding the opinion that the red corpuscles of human blood are not provided with nuclei; and then quotes Longuet as saying:—

"With man and other mammiferous adults the blood globules appeared to be deprived of nuclei. There is not even an exception in the family camelidæ, which, by the form of their globules, approach to those in which the presence of nuclei is not doubtful. That which has been taken for a nucleus is but the thin, central part of the disc. This remark, already made by Hodgkin and Lister, has been confirmed by Henle, Donné, Wharton Jones, &c., notwithstanding various micrographers admit that sometimes among the ordinary globules without nuclei one meets with those that appear nucleated. Such, at least, is the result of the observations made by Wharton Jones, Schultz, Nasse and Busk, with man and other mammifera."

As all investigators are so nearly in harmony on the subject of the anatomy of these organic forms, the methods of observation having been uniformly the same, it is deemed unnecessary to make further quotations.

In presenting my own views in contradistinction to the foregoing, I wish to call especial attention to my method of investigation. Heretofore all examinations of blood corpuscles have been made by transmitted light, from which we might anticipate, *a priori*, that, with instruments of the same degree of perfection, similar results would be obtained. On the contrary, all of the research upon which my present convictions are based has been prosecuted by the use of reflected light, the object resting upon a polished jet slide.\*

The accompanying diagrams set forth faithfully the appearance made manifest by this method when properly pursued.

\* Those who wish to repeat these observations, by means of Wale's Illuminator, will find it indispensable that the object-glass be arranged for uncovered objects, and the discs spread thinly over the surface of the slide. Corpuscles found in defibrinated blood are the best for observation. Those found in rouleaux do not show the nuclei satisfactorily.

DIAGRAM I.—*a*, represents the perfect, human blood corpuscle. It will be seen that the centre presents a slight elevation, surrounded by an annular depression, while the circumference of the disc is, comparatively, thick, smooth and rounded.

DIAGRAM I.

*b*, represents a disc with serrated and shrivelled margin, with a perfect central elevation remaining.

*c*, a corpuscle without the central elevation.

*d*, is a hypothetical diagram of a disc placed upon its edge.

DIAGRAM II.

DIAGRAM II.—*a*, represents the perfectly formed, oval and characteristic disc, or globule of the frog. In the central portion may be seen an oval depression, in the centre of which can be observed the elevation representing the nucleus. The margin is shown to be rounded, smooth and thickened.

*b*, is like the former in every respect except the central papilla is absent.

*c*, a shrivelled corpuscle.

*d*, a corpuscle, as it would appear set upon its edge.

It will be seen from the foregoing explanation that these bodies do not all possess a nucleus, or central elevation. In fact, there are in both the human blood and in

that of the frog a large proportion, perfect in every other respect, that do not possess this peculiarity. Whether this fact is due to an absence of this feature on one of the surfaces of the corpuscles or to its non-existence in a certain percentage of cases, I am undetermined.

I have, as yet, examined but few pathological specimens. In one instance, however, in a case of advanced typhoid fever, the corpuscles, without exception, were found serrated, shrivelled and distorted in the most remarkable manner, with the exception of the nucleated centre. This seemed to maintain its integrity.

The reader, by reference to the diagrams, will observe that the corpuscles, both of the human and reptilian blood, are analogous in their general features, as, witness the elevated nuclei in the centres, the surrounding depression and the elevated margins, together with the entire absence of nuclei in nearly equal proportions of each. It will also be observed that certain numbers are imperfect in outline, as if affected by disintegration; and this is true of a similar proportion of every specimen that I have ever examined. This apparent analogy of form and feature between mammalian and reptilian corpuscles only supports what is generally acknowledged should obtain with these bodies in order to bring them in harmony with the known homology of other tissues, from whatever species of animal obtained. I believe that it is never denied that nerve, muscular, bony and other tissues, when compared with their kind, are essentially alike in their anatomical constitution. Why should blood tissue form an exception to this general rule? Do not the corpuscles perform the very same function, whether floating in the blood of a reptile or in the vessels of man?

With one exception I have not, as yet, extended my observations to the condition of blood discs in the various parts of the body. In the spleen pulp I found them mainly imperfect in form, being generally serrated, shrivelled, and seldom nucleated. Hæmatine, in granulated masses, was seen interspersed among the corpuscles. White corpuscles, in great numbers, were arranged around the margin of the specimen.

The Illuminator does not reveal anything unusual concerning the white corpuscles; they merely appear as non-nucleated, globular bodies. It is remarkable, however, that they never associate themselves with the red discs, there seeming to be a perfect antagonism of position.

THE announcement of the death of Dr. Calvin G. Page will carry surprise and grief to a large circle of acquaintances and friends. His fellow citizens in general, also, among whom he was widely known as a man of uncommon intelligence, energy and public spirit, will receive the sad tidings with deep regret. Dr. Page was a man of great worth, and warmly beloved by those who knew him, both in his profession and out of it. He was the writer of the last report of the School Committee—a document marked by excellent qualities of judgment, courage and taste. He served honorably through three years of the war, and his early death is to be traced directly to a disease contracted from his exposures in that arduous work. He is one more victim added to the vast multitude of our noblest and best sacrificed in that dread struggle for the salvation of the country. His spirit has ascended to heaven in the very hour when flowers were strewn and bells tolling in memory of the great army of his departed comrades. His memory will long be green in many a loving heart.

To the above appropriate words, which we take from the Boston *Transcript*, we must be permitted to add that the profession of which Dr. Page was a valued member may claim to be among his most prominent mourners.

#### NOTES FROM L'UNION MEDICALE.

*Salivary Calculi.*—M. Paulet, at the Imperial Society of Surgery, exhibited two salivary calculi which he found in Wharton's duct, in a patient affected with a purulent discharge issuing from the floor of the mouth. The calculi were in the duct of the left side, and M. Paulet extracted them by excision. He ascertained that the sub-maxillary glands of both sides were stuffed with calculi. These stones are not rare in Wharton's duct; as M. Paulet has collected 65 cases of them, while the foregoing is the only instance in which he is cognizant of their presence in the sub-maxillary glands themselves. M. Panar, however, presented a salivary calculus, which he had extracted by excision from the sub-maxillary gland. In this case pus was seen issuing from the open orifice of Wharton's duct. M. Desormeaux remarked that he had once extracted a stone from *Stenor's duct*.

At the same society M. Liégeois read a

paper, the subject of which was the *spermatic fluid*. He cited the investigations of various observers besides himself. The following are his conclusions, viz.:—1st. Every healthy man—adolescent, adult, or aged—who is free from anomalous peculiarities, defective conformation, and traces of former affection of the organs of generation, has in his spermatic fluid the essential elements of fecundation. 2d. Diseases—acute, chronic or constitutional—in the adult do not appear to produce *azoospermia*; which, however, is often the consequence of them in men of advanced age. 3d. *Blenorrhagic epididymitis*—the most common of all the affections of the internal organs of generation—almost always, if bi-lateral, definitively prevents the excretion of *zoösperms* and becomes thus a cause of sterility; when it is unilateral, it by sympathy induces a lowering of functional activity in the healthy testicle, diminishing the quantity of spermatozoa furnished by it, and thus exerting an unfavorable influence on the fecundating properties of the spermatic fluid; non-blenorrhagic epididymitis, whether bilateral or unilateral, is far from having the same degree of unfavorable influence as the blenorrhagic on the secretion and excretion. 4th. Affections involving the testicular parenchyma are always grave as regards sterility, whether both glands or one testicle only be concerned; of all these last-mentioned affections chronic syphilitic orchitis is the least to be dreaded in this respect, since the sterility it generally induces may disappear under appropriate treatment. 5th. Lesions which he denominates *peri-testicular*, *peri-epidymal*, and *peri-deferential* do not appear notably to affect spermatic secretion or excretion—leaving out of view varicocele, which, when carried to a certain point, induces testicular atrophy, and consequently *aspermatozia*. 6th. *Spermatorrhœa*, in the generality of cases, does not modify the spermatic secretion; in certain individuals affected with it, however, *azoospermia* may exist, even though they may not have reached that degree of prostration to which the affection often leads.

*Accidental Wound of an Artery during an Operation for Vesico-vaginal Fistula; Fatal*

*Result.*—M. Paul Horteloup communicated the case to the *Société Impériale de Chirurgie*. He was operating at the Hôpital Beaujon for vesico-vaginal fistula, and was just making the last cut with the bistoury when a jet of blood struck his face, and the vagina was filled at once by the hæmorrhage. Neither ice nor the tampon stopped the flow, which was, however, controlled by seizing the posterior lip of the fistula with a screw forceps and a polypus forceps. The tampon, injections of ice water into the bladder, compresses wetted with cold water to the abdomen, were used, and wine, beef-tea and ice administered. A few days after, the forceps were detached in the movements of the patient, and a new hæmorrhage set in, to be controlled as before, with the forceps. The patient, however, had lost so much blood that she sunk five days subsequently.

At the autopsy there was found general acute peritonitis, and a division through two thirds the diameter of the left utero-ovarian artery.

We perceive that advertisements of Female Medical Schools are making their appearance. Though our tastes are not in favor of Female Physic, we hold to the motto "a fair field and no favors asked"; and we therefore say, if medical journals are to be cumbered with advertisements, let the female persuasion have their share. It is another matter with certain extra-pharmaceutical preparations.

MASSACHUSETTS MEDICAL SOCIETY.—For the following report of the first day's proceedings we are indebted to the *Boston Daily Advertiser*.

The annual meeting of the Massachusetts Medical Society began in this city on Tuesday morning, June 1st.

At ten o'clock the members of the Society visited the Massachusetts General Hospital and the Boston City Hospital, where various interesting operations were successfully performed.

At 12 o'clock the members assembled in Bumstead Hall, Dr. Charles G. Putnam, of Boston, the President, in the chair. Two hours were passed in the reading of papers

which had previously been announced, as follows:—

Myxoma, or Hyperplasia of the Villi of the Chorion. By Alexander D. Sinclair, M.D., Boston.

2. General Management of the Insane. By Merrick Bemis, M.D., Worcester.

3. Formation and Significance of Renal Casts. By Robert Thaxter Edes, M.D., Hingham.

4. Physiological Action of Bromide of Potassium, as determined by experiment on the lower animals and man. By Robert Amory, M.D., Brookline.

At 4 o'clock, a second meeting was held in Bumstead Hall, when Samuel G. Webster, M.D., of Boston, read a paper on the Microscopical Study of the Nervous System.

*Evening Meeting.*—The annual business meeting of the Councillors of the Society was held at the Society's rooms, Temple Place, on Tuesday evening, Dr. C. G. Putnam presiding.

The Treasurer's report, which was read and accepted, stated that the receipts of the Society during the past year, including a balance of \$2022.28 from the previous year, were \$9384.97; the amount expended was \$7468, leaving a balance of \$1916.27. The principal expenditures—nearly \$2500—had been for publications. The gross amount received for assessments during the past year was \$3840, of which \$1139.70 was refunded to District Societies, leaving a net amount of \$2900.

The invested property of the Society amounted to \$30,420.17, the income from which during the year was a trifle over \$2000.

The Secretary read a list of sixty-six members who had been admitted to the Society since June 3d, 1868, and also a list of twenty members who had died during that period.

A letter was read from a member of the Society offering a prize of \$30 to any medical student of this State, or any regular physician of less than two years' standing, for the best paper on "The Physiological Action of some Drug of the *Materia Medica*, as determined by stated and original experiment."

The Committee on Resignations reported that the following members, being above 60 years of age, had signified their intention to retire from active membership:—A. W. Draper, West Roxbury; S. A. Toothaker, Wilmington; Joshua Porter, North Brookfield; S. D. Townsend, Boston; E.

Reynolds, Boston; C. H. Allen, Cambridgeport; David Bradford, Montague; H. C. Perkins, Newburyport; Enoch Cross, Newburyport.

The reports of several committees were read and accepted.

On motion of Dr. B. E. Cotting, of Roxbury, the following rule was adopted:—

“That all reports upon scientific subjects and scientific papers read to the Society be referred to the Committee on Publications, with instructions that they refer each separately to a committee of experts, whose names shall not be disclosed; and that such as said committee of experts shall designate shall be published at the expense of the society, if there be unappropriated funds in the treasury.”

The following were the officers elected for the ensuing year:—

*President*, Dr. C. G. Putnam. *Vice President*, Dr. H. L. Sabin. *Corresponding Secretary*, Dr. C. D. Homans. *Recording Secretary*, Dr. C. W. Swan. *Librarian*, Dr. J. C. White. *Treasurer*, Dr. F. Minot.

The orator chosen for the next anniversary meeting was Dr. Wellington, of Cambridge, and Dr. George H. Lyman, of Boston, was appointed chairman for that occasion.

The following gentlemen were chosen on the committee of arrangements:—Drs. C. D. Homans, R. M. Hodges, J. N. Borland, A. Coolidge and A. P. Hooker.

Boston was selected as the place of the next anniversary meeting. The meeting then adjourned.

The annual meeting of the society was held in Bumstead Hall, at 10 o'clock, Wednesday morning. At 1 o'clock, Dr. Alfred Hitchcock delivered the annual address. The proceedings closed with the anniversary dinner, which was served in the Music Hall at 2 o'clock, under the presidency of Dr. J. B. Upham.

**VALUE OF THE RHINOSCOPE.**—Dr. F. I. Knight, at the March meeting of the Suffolk District Medical Society, reported the removal of three polypi with the aid of this instrument. The patient, a young lady, 20 years of age, came to him with the following history. Eight months before, she washed her hair, and sat down by the window to dry it. She “took an awful cold,” had coryza, &c., and the next day and ever since had noticed complete obstruction of the right nostril on expiration, and considerable obstruction on inspiration. There had been no discharge from the nose since

the first few days. Her voice was much affected, she talking as if she was suffering from a severe cold in the head all the time. She had been told that she had catarrh, and had been given various solutions to sniff up the nose. On examination of nasal passages anteriorly, nothing definite could be seen. A large nasal probe could be passed through both nostrils to the pharynx. On examination of posterior nares with the rhinoscope, the obstruction was seen to be due to two large gelatinous polypi, moving from the mucous membrane over middle and inferior turbinated bones on the right side, one of which on expiration shut down like a valve over the inferior meatus. There was also a small fibrous polypus on the posterior surface of the soft palate. The polypi were all removed posteriorly by forceps applied with the aid of the mirror. The relief to the respiration and voice was of course immediate.

**RESULTS OF TRANSFUSION.**—Professor Landois, of the University of Griefswald, who has interested himself much in the subject of transfusion, after giving a critical account of the most recent publications on the subject, thus sums up, in a recent number of the *Wien. Med. Woch.*, the results that have hitherto been obtained:—1. Transfusion has been performed ninety-nine times in cases of hæmorrhage, in eleven of which cases no successful result was even possible. Of the remaining eighty-eight cases, sixty-five were attended with success, twenty were unsuccessful, and in three the result was doubtful. 2. It has been performed twelve times in cases of acute poisoning, one of these being hopeless. In three the results were favorable, and in eight unfavorable. 3. For various forms of disease attended with exhaustion, it has been resorted to forty-three times, the most unfavorable prognosis having been frequently delivered. In these the results were favorable in twelve, unfavorable in twenty-one, and doubtful in nine, while in one case it was a mere desperate experiment. Professor Landois observes that these statistics speak very satisfactorily for transfusion, and that the results would be far more favorable if this almost harmless operation were not usually driven off to the last minute.—*Medical Times and Gazette*.

In a paper on the Pathology of Typhus, and its connection with lesion of the cervical portion of the great sympathetic nerve, Dr. R. Beveridge says:—In a case of ex-

ophthalmic goitre, which occurred in the Aberdeen Infirmary, under the care of Dr. Reith, and of which the particulars were published in the *Medical Times and Gazette* of Nov. 11, 1865, I demonstrated the existence of extensive enlargement of the cervical ganglia of the sympathetic, and from that case was led to examine the condition of the nerve in typhus, with the result of finding in every case alteration of structure there to a greater or less extent.

From 1863 to 1865 an epidemic of typhus prevailed in Aberdeen, and during that period upwards of 1700 cases were treated in the Infirmary, and of these about 230 died. *Post-mortem* examination of these fatal cases was made as often as permission could be obtained from the relatives (which unfortunately was most frequently refused), but for the first eighteen months without any definite result being obtained. All the important organs of the body were examined, but especially the intestines, lungs, and brain; and in none was any constant lesion found. The intestines were usually found natural; sometimes, though rarely, with slight appearances of congestion here and there—never with ulceration. The lungs never presented any trace of deposit; they were usually natural, or with merely passive congestion behind, the result probably of position; sometimes this last was found to drift into low pneumonia. The brain usually presented the appearance of congestion, but without any effusion, and without any alteration in texture of the cerebral substance or of the membranes. It was not, however, till the sympathetic nerve was made the subject of examination that any definite result was obtained. When attention was directed to this, it was found to present lesion in the form of enlargement caused by granular deposit of some of the cervical ganglia, in every case examined. [These amounted to ten in number.]—*Medical Times and Gazette*.

**HYDROPHOBIA IN A FLOCK OF SHEEP.**—During the past two or three months hydrophobia has been alarmingly prevalent in the neighborhood of Preston, and especially so in the town itself. Many valuable dogs of all breeds have been destroyed at the police station with prussic acid, the whole number, good, bad, and indifferent, amounting to two or three scores or more. About three weeks ago, nine lambing ewes, the property of Mr. Draper, Bradley Hall Farm, Croston, six miles from Preston, were bitten by a strange dog, and having since exhibited undoubted symptoms of rabies, have just

been all destroyed. The lambs were preserved.—*Medical Press and Circular*.

**CRIES OF A FÆTUS IN UTERO.**—The *Scalpel* states that Dr. Dubreuilh, of Bordeaux, had under his care a girl of 16, who, towards the end of gestation, was seized with eclampsia. Chloroform was used, and a very small male child was extracted. The breech of a second child now presented, and, just as the water broke, the persons present heard the cries of the child, as if they issued out of a box, and they continued until the delivery was effected by the feet. The cries were heard at the moment the accoucheur pushed up the breech to seize the feet. Air had probably then penetrated into the uterus, which was not quite filled by the second fetus, and the latter, having inspired it, began to cry.—*Ibid*.

**URINARY INFILTRATION IN RELATION TO GANGRENE.**—G. Simon (*Deutsche Klinik*, 15, 1869) makes the following statements, based upon numerous experiments made on the lower animals:—

Acid wine, if pure and in small quantities, is as innocuous as water in its effect upon animal tissue. If alkaline, or if mixed with sufficient blood, pus or mucus to make it alkaline, its injection into animal tissue produces all the destructive effects which are usually ascribed to urinary infiltration.

Acid urine, far from tending to cause decomposition of tissue, seems to act as a preservative—like a solution of common salt. A portion, placed in a tight vessel, with a small quantity of putrescent animal tissue, remained acid five or six days, and on the tenth day was not yet decomposed.

Acid urine was allowed to remain for a long time in contact with the subcutaneous tissue, in living animals. From the absence of evil consequences in this, and all the preceding experiments, it is concluded that the danger from operations such as the supra-pubic puncture is not due to the presence of urine *per se*, but to that of alkaline urine—and that the appropriate precaution in such operations, is treatment directed against catarrh of the bladder, if any exist. It is also needless to keep the patient lying upon his face, or to leave the catheter in the puncture continuously.

The really important cause of gangrene in urinary infiltration is concluded to be the pressure of fluid upon the tissues in which it lies. The author has produced the same effect by simple water, injected so as to exert a constant pressure under the cutis.—*Allg. Med. C. Ztg.*, No. 31. D. F. L.

## Medical Miscellany.

**AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.** *Special Circular to Persons Interested in the Use of the Microscope.*—In making arrangements for the meeting of the American Association for the Advancement of Science, to be held at Salem, commencing at 10 A.M., August 18th, 1869, the Local Committee, in order to give encouragement to the general and increasing interest in the use of the Microscope, have decided to furnish rooms for the display and comparison of Microscopes, Objectives, Accessory Apparatus of all kinds, Test Objects, and Objects of Scientific and Popular interest.

It is intended to have as complete a collection as possible of instruments of both American and Foreign manufacture. Those who are possessed of Microscopic stands, Objectives, or Accessory Apparatus in any way remarkable for excellence of performance or design, are requested to bring them to the meeting.

The objects of this exhibition will be to assist the progress of scientific research, by social intercourse and a full comparison and discussion of whatever is new and important in microscopical investigation, and to encourage the manufacture and use of this valuable instrument.

Arrangements have been made to give ample opportunity for the use of the Microscopes both day and evening. A safe place has been secured for the deposit of instruments sent beforehand to the care of Mr. Bicknell, or brought by visitors who do not wish to keep them in their own possession.

A Sub-Committee has been appointed by the Local Committee to make the necessary arrangements. Further information relating to the subject can be had by addressing

EDWIN BICKNELL,

*Sec'y of the Sub-committee,*

Peabody Academy of Science, Salem, Mass.  
Salem, May 24, 1869.

**PARIS FACULTY OF MEDICINE.**—At the Faculté de Médecine de Paris, Dr. Regnaud, Professor of Pharmacology, was prevented from giving two of his lectures by the noise and outcries of his students. The excitement against the Professor is attributed to his severity at examination.

**MESSRS. CODMAN & SHURTLEFF,** makers and importers of Surgical and Dental Instruments, 13 and 15 Tremont Street, Boston, write us that they have been Dr. Anzoux's agent for the past ten years. They have printed copies of his catalogue.

THE Massachusetts Medical Society having offered a prize of fifty dollars for the best dissertation "which shall describe in plain language, briefly, an effective and ready method of ventilating sick rooms—one that can be put in operation at once, at the moment needed, with least difficulty and expense, in houses of ordinary construction," we hereby offer, as the only possible way of fulfilling all the conditions demanded, the following:—

PRIZE ESSAY ON AN EFFECTIVE AND READY

METHOD OF VENTILATING SICK ROOMS, &c. &c. &c.

*Pull down the upper window-sash and leave the fire-place open.*

The prize above mentioned may be sent to the Publishers of THE MEDICAL GAZETTE.—*N. Y. Medical Gazette.*

**PROFESSOR OPPOZZER,** of Vienna, has received the cross of knighthood of the order of Leopold. The rank of Aulic counsellor has been conferred on Professors Brücke and Skoda, of Vienna; and that of counsellors of state on Professors Jaksch and Halla, of Prague.—*British Medical Journal.*

**DR. HEBERT** says:—What every family should keep in mind is this, that mustard plasters ought not to be made with hot, but with lukewarm water.—*Medical Press and Circular.*

## MEDICAL DIARY OF THE WEEK.

MONDAY, 9, A.M., Massachusetts General Hospital, Med. Clinic. 9, A.M., City Hospital, Ophthalmic Clinic.  
TUESDAY, 9, A.M., City Hospital, Medical Clinic, 10, A.M., Surgical Lecture. 9 to 11, A.M., Boston Dispensary. 9-11, A.M., Massachusetts Eye and Ear Infirmary.  
WEDNESDAY, 10, A.M., Massachusetts General Hospital, Surgical Visit. 11 A.M., OPERATIONS.

### MANIA TRANSITORIA.

By EDWARD JARVIS, M.D., of Dorchester.

THIS is a form of mental disorder which suddenly appears in persons previously sound or not disposed to be unsound in mind; it has a short duration and suddenly disappears.

This is not exclusively a new or an old doctrine, but it has been taught in France and Germany for many years, by the managers of the insane, and by writers on these topics. It is recognized by psychological authorities in Great Britain. It is admitted and established by jurists and courts in Europe, in their management of persons who have committed acts which would otherwise have been considered as crimes, and for which they would have otherwise been doomed to death on the scaffold.

The case of Andrews, who was tried at Plymouth in December last, for homicide, has brought this subject prominently before the public here. As there is a difference of opinion in regard to this doctrine, especially in its application to the case of Andrews, it may be well to present the views of those who have written upon it, in connection with an account of Andrews's agency in the homicide, and of his trial.

Dr. Henry Maudsley, manager of a lunatic asylum at Hanwell, near London, and one of the editors of the *Journal of Mental Science*, says, "Cases of insanity are occasionally observed in which an attack of mania suddenly comes on, and soon passes away, so that although there is no epileptic fit, one can scarce avoid looking upon the attack as a sort of epilepsy. Now this Mania Transitoria may take on the homicidal form."\*

He quotes from the *Journal de Med. et Chir. Pratiq.*, 1833, the case of a shoemaker, who was of industrious, sober habits. He arose early one morning to go to work. In a short time his wife was struck

with his wild look and incoherent talk. He suddenly (*tout à coup*) seized a knife and rushed upon his wife to kill her. She had hardly time to escape with her child. Dr. Lowenthal was called. He bled and gave other remedies to the maniac. In the afternoon he was quiet. In the evening he regained the use of his faculties, but he had no recollection afterwards of the events of that morning.

Castelnau calls this *La Folie Instantanée, temporaire, passagère*, "mania instantaneous, transitory, temporary, fleeting, a mental disorder, which breaks out suddenly, like the sudden loss of sense in some physical diseases, and the subject is urged in a moment to automatic acts, which could not have been foreseen."\*

"The first act of the mania may be homicide, and the disease may pursue its course under the continued or intermittent form, but when the act of violence or homicide is the only maniacal manifestation, it is instantaneous, temporary, fleeting, transitory, insanity according to Henke, Marc, Cazauvielh, &c."

He quotes, in illustration, from Hiem of Berlin, the case of a councillor of state, who had ever enjoyed good health. He suddenly awoke one night, breathing stertorously. His wife endeavored to aid him. He assailed her with the most violent fury, and tried to throw her out of the window. After a struggle for half an hour he was exhausted. An emetic put an end to the paroxysm, and for fourteen years he had had no other attack.†

A laboring man of Gard, returning from his work, met his wife, and asked her if supper was ready. She immediately seized a knife and struck him a fatal blow. She had not been insane, though excitable, and belonged to an insane family.‡

Castelnau, referring to this form of mental disorder, says, "I could show by facts, already so numerous, recorded in the works of physicians devoted to the study of in-

\* Dr. Ph. Boileau de Castelnau in *Annales d'Hygiène Publique et de Médecine Légale*, xlv. 217.

† Castelnau, *Ann. Hyg. et Méd. Lég.* xlv. 222.

‡ Ibid., 993.

\* *Jour. Mental Science*, ix. 335.

sanity, and the observations of the insane, the existence of a mental malady which society has the greatest interest to know, in order to prevent consequences dangerous to the community and to the person affected."\*

Again Castelnau says, "We could cite a great number of facts, but these are sufficient to show that the various kinds of insanity, as of all the diseases of the organism, can establish themselves in a manner either progressive or sudden, and have a progress slow or rapid, continued, intermittent, or temporary."†

After a great variety of facts and arguments, Castelnau, at the end of his essay, says in conclusion, "There exist these instantaneous changes in the mental faculties, that is, instantaneous insanity."

"These changes have their first and only manifestation in a single act of qualified crime.‡

Castelnau's essay was published in 1851; seven years later, Dec. 14, 1858, M. Le Dr. A. Devergie read, before the Imperial Academy of France, an essay on the questions, "Where does reason end? Where does insanity begin?" This was printed in the *Annales d'Hygiène Publique et de Médecine Legale*, in 1859, vol. xi., second series. He confirms the opinions of Castelnau, in regard to instantaneous and transient insanity, except that he qualifies them with the certainty or probability, that all or nearly all these cases had been preceded by hereditary taint or some mental disease or irregularity in greater or less degree.

"Besides those cases of insanity produced under all these causes, is another mode of alienation, to which they give the name of *Transitory Insanity* (*folie transitoire*), that is to say, without preceding apparent symptoms, without cause, near or remote, appreciable to the world, bursting out as suddenly (*brusquement*) as a clap of thunder, and ceasing completely with a criminal act."§

"No motive for the act, either in ungoverned passions, or in acquired ideas; previous character and manner without reproach; absence of hallucinations; the explosion of the mania manifesting itself in one act of violence or crime, and the immediate return of reason after this act is accomplished; these, in my opinion, are the characters of *transitory insanity*."||

Devergie qualifies this description as above indicated:—"Nevertheless the word *transitory*, perfectly just for the world, in the sense that the mania was fleeting (*passagère*), although the act was of the most criminal nature, does not seem sufficiently exact for the physician. The persons of this description should not be considered as sound in mind when the idea of crime suddenly rises within them, and becomes the ruling thought, irresistible, stronger than their own will. The antecedents of their families, hereditary taint, divers acts of social life, propensities and tastes perverted, tendencies to silence and abstraction, thoughts of suicide, for years existing in many, have been the forerunners of the sudden outburst of irresistible criminal mania."\*

Devergie quotes the case of a young man of 19, son of a merchant of Bordeaux. He had been most regular and exemplary in all his previous life, an affectionate brother, dutiful son, faithful to his employer, a banker, and the heir of an immense fortune, but he was the child of insane parentage, and had a mother-in-law for whom he had a deep aversion. There was a dinner-party at his father's house, which passed without unusual incident. "At the time of the dessert, Julius, the youth, left the table, and went to the hall to warm himself; the fire was not burning; he then went to his chamber, took his gun and straw hat to walk in the fields as he was accustomed to do. Then the thought of suicide, which had troubled him for a month, suddenly presented itself, and as suddenly changed to the thought of killing his mother-in-law. He threw down the gun, went to his brother's chamber, took two pistols, which had been loaded three months, leaving his own pistols that he had loaded the evening before. He went to the dining-room where his mother-in-law was sitting at the table with his father, and discharged one of the pistols into her temple."† He was rational immediately afterwards, and, so far as is known, remained sane.

Upon this case Devergie remarks:—"If the act which young Julius committed was one of mania, it was in him a passage sudden and rapid from reason to insanity, and a return as sudden from insanity to reason. This then is a very exact example of that species of mania which is called *transitory*." This case was submitted to MM. Gintrac and Delafosse of Bordeaux, Calmiel, Tardieu

\* Castelnau, *Ann. Hyg. et Med. Leg.* xlv. 216.

† *Ibid.*, 398.

and Devergie, who gave their opinion, "that Julius, at the moment of this action, had not the possession of his freedom of will," and the court and jury acquitted him fully of the charge of crime.\*

These doctrines are sustained by French lawyers, and put in practice by French courts and juries, in the trials of cases of this nature. "Bellard, a jurist (*jurisconsulte*) of high character, whom no one suspects of being indulgent, recognizes the reality of instantaneous insanity." He says, "There are some madmen whom nature condemns to eternal loss of reason, and others who only lose it for a moment (*instantanément*) by the effect of some great grief, surprise or other cause of this kind. There is no other difference between these two forms of mania than that of duration; and one whose head is turned for some hours or for some days is as completely insane, during this ephemeral action, as the one who is mad for many years." *Les aliénés devant les cours d'Assises.*†

To this Devergie adds, "So in the short period of thirty years or more, we have passed from incredulity, I may say, from ignorance the most profound of the nice distinctions of insanity, with such immense advance, that now our judges and juries accept as founded on evidence, not only delusions on a single point, monomania, but even those transitory aberrations of reason, which, in the judgment of the world, transform a man of previously honorable character into a criminal, and one so much the more wicked because he has covered his perversion of heart so completely as to conceal, through a long period of years, the baseness of his act under the garb of the most irreproachable life."‡

Esquirol says, "These deplorable homicidal impulses are spontaneous and fleeting, and without habitual delusion."§ Referring to murder by one in this condition, he says, "This presupposes the suppression of all intelligence, all sensibility and all volition. The following fact will best explain my meaning. A man, 32 years old, tall, thin in flesh, of a nervous temperament, amiable disposition, was educated with great care, and accomplished in the fine arts. He had had a cerebral affection from which he had recovered many months previous to his arrival in Paris, two months ago. There he conducted himself with great propriety, until one day, when he en-

tered the Palace of Justice, and there threw himself upon a lawyer and seized him by the throat. He was arrested and taken to prison, and put under my care on the same day. At my first visit, on the next day, he was calm, without anger or resentment, had slept all night, and had sketched a landscape. He spoke of his going to the court room the evening previous, coolly, but had no recollection of his conduct there or of his motives. Nor did he manifest any regret. He answered my questions courteously and with an air of sincerity. 'I went to the Palace of Justice, as I would to any other place, without any special purpose, merely as a sight seer. I not only had no ill will against the advocate, but did not even know him. I cannot understand how I could have committed such an outrage.' When I said, 'that it could be explained only by the sudden attack of some disease,' he said, 'you may explain it as you please, I am not conscious of having been ill, and I cannot tell how this could have happened.' During the three months that he remained under my observation he manifested not for an instant any disorder of the mind."\*\*

Castelnau says, "There is no want of authorities to establish the doctrine of instantaneous insanity." The observations made by writers on medical jurisprudence (*medicins legists*) of the present day leave no doubt of the existence of this mania of a few instants, during which men, who have never manifested insanity, all at once (*tout à coup*) are completely deprived of their reason, and give themselves up to the most deplorable excesses. The learned chief editor of *Journal du Medecin et de Chirurgie Pratique*, offers five examples of this kind of mania. In four of these, accidental circumstances only prevented persons, whose previous life had been irreproachable, from committing crimes. The fifth case was that of a woman who killed her mother and three others, and wounded a fourth person.†

Tuke quotes and refers to a large number of cases of impulsive homicidal mania, from Marc, Otto, Michu, Esquirol, Ray, and others, showing that some had delusions, some had inherited disease or defective cerebral organization, others had manifested irregularities of mind before, and some after the outbreak, and of a few nothing is shown except the single fact of sudden and short mania. Following this description of these cases, he adds:—

"To this analysis of cases, a brief sum-

\* *Ann. Hyg. et Med. Leg.* xi. 2d Ser. 499.

† Castelnau in *Ann. Hyg. et Med. Leg.* xlv. 217.

‡ *Ann. Hyg. et Med. Leg.* xi. 2d Ser. 402.

§ *Malad. Mentales, sous les Rapports Médico-Légaux*, ii. 104.

\* *Malad. Mentales sous les Rapports Médical et Médico-Légal*, ii. 102. † *Ann. Hyg. et Med. Leg.* xlv. 221.

mary of the chief characteristics of homicidal insanity may be added. It manifests itself under very different mental conditions. It may or it may not be associated with decided lesions of the intellect. It may or it may not be impulsive in character. It may or it may not be preceded by appreciable premonitory symptoms. It may or it may not be manifested in early life. However, careful investigation will reveal, in the majority of cases, a disturbance, more or less, of the intellectual as well as of the moral faculties; leaving still a considerable number of cases in which there is a sudden, blind, motiveless, unreasoning impulse to kill."

"An inquiry into the patient's history will generally detect a change in the character. This, however, obviously cannot be looked for in cases where the mental disorder can be traced back into infancy or where the intellectual or moral defects are congenital."\*

In the analysis of cases, Tuke does not deny the facts as they are presented, the suddenness of the outbreak, the shortness of the paroxysm, nor the suddenness of the cessation, but he adds, that in most of the cases, the sudden and transitory disease was grafted on a mind, which was prepared for this attack by hereditary predisposition, by perversions, or eccentricities, or was otherwise unsound, though not manifestly insane, and that subsequent history showed that most of these were insane, and that after all these deductions, there were a considerable number in which no such preparatory condition could be proved.

Fortunately for the safety of society, these cases of sudden outbreak of mania in persons of sound mind are rare, and confined mostly to those whose brains are imperfect from heritage or impaired by intemperance, or indulgencies, eccentricities, or irregularities and indiscretions, which, though not amounting to disease of the mind nor recognized as such, yet prepared the way for its appearance, whenever a suitable exciting cause should present itself.

The seventy-five to a hundred cases of transitory mania reported are gathered from wide and manifold opportunities of observation in Europe and America, principally in France and Germany. Some psychologists of large experience have met none. Dr. Bell, at the trial of Rogers, after stating that he had had upwards of a thousand patients under his charge,† said, "I have heard of many cases where the disease was

only transitory, from Dr. Woodward and others, though I am not familiar with cases of such short duration, under my own observation."\*

Dr. Choate said that he had had charge of between three and four thousand patients at the Taunton Hospital in the course of fifteen years, and in that time he had not seen any such case.†

Although the cases of complete mania transitoria, involving the three essential elements, sudden outbreak, short duration, and sudden cessation are very rare, yet cases including one or more of these elements are more common.

#### SUDDEN OUTBREAK.

Pritchard says, that "many instances are known, in which a sudden impulse to commit some atrocious act, has arisen in the mind of a person otherwise apparently sane, and certainly in full possession of his intellectual faculties."‡

Esquirol says, "There are other monomaniacs who kill by instinctive impulse. They act without consciousness, without delusion, without motives. They destroy by a blind impulse, instantaneously, independent of their volition."§ Elsewhere, he speaks of persons who suddenly (*tout à coup*) change their relations to persons and things. They hate those whom they loved before, they are at war with all the world; a woman, the very image of candor and virtue, as meek in temper as modest in manner, who only speaks words of tenderness and generosity, a good daughter, wife, mother, all at once (*tout à coup*) she loses her reason. Her timidity is changed into audacity, her sweetness into ferocity, she now offers nothing but injury, blasphemy, obscenity; she exposes her person nakedly; she threatens her father, beats her husband, strangles her children."|| With a few the impulse is so violent and instantaneous there is no struggle of the will to resist, and the act follows immediately."¶

Esquirol quotes the case of a teamster from Le Marcure de Souabe, who "left home in perfect health, was suddenly (subitement) attacked with mania on the road. At Nogglingen he abused a woman. At Unterlobengen he walked in front of his team with a hatchet in his hand. Before reaching Hussenhofen he struck a woman, the first person he met, several blows with his hatchet and left her prostrate in the ditch by the side of the road. Next he split open

the head of a boy 13 years old. Then he buried his hatchet in the skull of a man 30 years old, and spilled his brain on the highway, and gave him many more blows on the body. Then he left his hatchet and his team and went on alone. Meeting two Jews, he attacked them, but they escaped. Next he attacked a peasant, who resisted him, and raised help to arrest him. They showed him the dead bodies. He then said, 'It was not I, but my evil spirit that committed these murders.'<sup>†</sup>\*

Castelnau says, that to numerous authorities already cited, he would add that of Dr. Lanier, a distinguished medical psychologist, who states in *Ann. Med. Psych.* that "from certain causes, persons are rendered powerless to resist an idea suddenly presenting itself to them, or not existing before. This idea may impel them to suicide, murder, theft, or other crime."<sup>†</sup>

Tuke quotes a case from Marc I. 242, of a man who in a paroxysm of fury cut his son's throat.<sup>†</sup>

Dr. Ray, after describing many cases, under various categories, according to their characters, says, "In the first group, we have the simplest form of homicidal insanity, in which the desire to destroy life is not only prompted by no motive whatever and solely by violent impulse, but without any appreciable disorder of body or mind."<sup>§</sup> He quotes a case from Dr. Otto, in *Edinburgh Phrenological Journal*, vi. 611, of a man 37 years old, who had had fits of giddiness. The state of his health was perfect, in mind as well as in body, when he walked out with his son, 10 years old. When near the water a strange feeling came over him, and it appeared like a matter of absolute necessity to drown himself and his son. While attempting it, the boy was taken from him; he plunged into the water, but was rescued and restored to his right mind. He then quietly described the whole, but could not explain the cause of the sudden rising of the desire to drown himself and his son. Probably the cause was a congestion of blood in the brain, such as had produced giddiness before."<sup>||</sup>

Dr. Ray gives another case, from Michu, sur la Monomaniac Homicide, 99. "A woman, ten days after confinement, suddenly having her eyes fixed upon her child, was seized with a desire to strangle it."<sup>¶</sup>

Dr. Ray, in the trial of Rogers, said

"Insane impulses often come on very suddenly, and appear to be uncontrollable."<sup>\*\*</sup>

At the same trial, Dr. Woodward said, "The outbreak or apparent commencement of the disorder is frequently abrupt and instantaneous."<sup>†</sup>

On the same occasion Dr. Bell said, "In cases of outbreak, the impulse is so sudden that the patient is hardly conscious of his acts."<sup>‡</sup> Tuke quotes a case from Marc of a man aged 60, dejected but not considered insane, who suddenly seized a hammer and struck a child on the head with it. He was much attached to the child.<sup>§</sup> And another, from the Newgate Calendar of William Brown, who strangled a child whom he accidentally met. He had never seen the child before, had no malice against him, and could give no motive for the act. He bore an exemplary character, and had never been suspected of being insane.<sup>||</sup>

Dr. Woodward, speaking of the cases of fifteen homicides under his care in the Worcester Hospital, says, that seven of them were not considered insane before they committed the act. They were at work at their several employments; were not observed by those associated with them to have any evidence of alienation; they knew as well as others right from wrong, how to manage their affairs, and conduct their business as well. The first overt act of insanity was the homicidal act, and that was impulsive.<sup>¶</sup>

Esquirol adds to the detailed description of a considerable number of cases of sudden and violent attacks of mania, "In these, the third series, the impulse is sudden, instantaneous (*subiter, instantanée*), without reflection, stronger than the will. The murder is committed without interest, without motive, and frequently upon the dearest friends."<sup>\*\*</sup>

#### SHORT DURATION.

Besides the cases already quoted and referred to, which are distinctly described as sudden in their manifestation and disappearance, and short in their duration, there are many others, the beginning and ending of which are not specifically mentioned, but only spoken of as short, transitory, fleeting. It is a natural inference, that these also were rapid in their development and cessation. Yet not to assume more than is given, these are placed in this separate chapter, leaving it for those to whom it may seem probable, to conclude that the

outbreak was gradual and even manifest, both in its approach and in its fading away.

These cases are simply reported as of short duration, spasmodic, comprising a single paroxysm of lunacy, and that characterized only in the propensity to commit an act of violence or crime, or the actual perpetration of the deed.

Bucknill, in a note to his essay on Criminal Lunacy,\* quotes the opinion of Dr. Forbes Winslow, given at the trial of Anne Brough for murder, that "cases of temporary insanity resulting in a desire to commit murder or suicide are very common."

Esquirol says, in one place, "These impulses are spontaneous and fleeting."† And in another, "The act accomplished, the access is over."‡

Dr. Ray recognizes this, when, at the trial of Rogers, he said, "The violence of the paroxysm may be as great in transient as in permanent mania." And again, "I do not consider the duration of the defendant's affection an essential particular."§

Dr. Woodward, in the same trial, said, "The impulse generally expends itself in a single act."|| "Cases of as short duration as the present are not infrequent, though they can hardly be called common."¶ "The outbreak of an insane person seems to be a safety-valve by which to let off his accumulated excitement."\*\*

#### SUDDEN RESTORATION.

"Recovery from insanity generally takes place gradually, though occasionally the disease may suddenly disappear, on the occasion of certain moral or physical impressions."†† In proof of this, Dr. Ray quotes several cases of sudden restoration to reason. One from Pinel, of a gentleman in a fit of depression or delusion, going to drown himself, but was attacked by robbers when near the water, and defended himself. While in this struggle, his reason returned, and his desire of self-destruction disappeared. Another case is from Dr. Rush, of a patient who became intensely alarmed when riding, by the horse running away. The fright took the place of the mania, which appeared no more. Rush mentions several other cases of sudden restoration of lunatics to their reason.

Prichard states several cases of sudden recovery in the English insane asylums.

Esquirol mentions a girl who was sud-

denly restored, by seeing the actual cauterization which he was about to apply to her body. And another, who, at the appearance of the catamenia, suddenly found her reason come back to her. He quotes a third case, in which the insane idea of long standing disappeared almost suddenly (*presque tout à coup*).\*

Dr. Ray, in the trial of Rogers, said, "Crises are sometimes observed in insanity, where the force of the disorder seems to expend itself in a single moment or upon some particular occasion."‡

#### CALMNESS AFTER THE ACT OF VIOLENCE.

After a deed of violence by the homicide, his agitation sometimes ceases, and he is as calm and indifferent as if he were merely an uninterested spectator. Peter Neilson, in Scotland, drowned four of his children in a pit, then returned and told the people what he had done. He went back to the pit with the people and saw the dead bodies, without emotion.‡ Rice, who, in Concord a few years ago, killed his father, in the house, with the tooth of a harrow, and then threw him down the cellar stairs, was immediately calm, sat down by his mother's side and told her that they would say that his father fell down stairs and broke his head in the fall. Dr. Woodward mentions the case of a man in the hospital who, in a sudden impulse of excitement, seized a bludgeon, and struck a deadly blow on the head of an inoffensive female. In a moment he was as cool as ever, and quite unconcerned, as if he had done no injury to any one.§

Esquirol says, "Some monomaniac homicides, after the act, appear to be relieved of all agitation and distress. They are calm, without regret. They contemplate their victims with a coolness, and sometimes with a sort of satisfaction.||

In the trial of Rogers, Dr. Bell said, "It is a well-settled fact that after paroxysms of violence the insane often appear calm and tranquil."¶ Dr. Ray said, "The calmness of the defendant after the homicidal act is in accordance with general experience."\*\* Dr. Woodward: "The calmness of the defendant after the act coincides with common experience."††

Henrietta Comier, who cut off the child's head and threw it into the street; the teamster who killed four persons and assaulted three others; the woman who killed her mother and three others; the youth who

shot his mother-in-law, and very many others described by Marc, Esquirol, Tuke, Ray, &c., were calm and even indifferent after the commission of their acts of violence.

#### ABSENCE OF MOTIVE.

Some lunatics, who commit homicide or other deeds of violence, have motives for their actions, which they recognize and acknowledge. But these are usually imaginary and out of relation or proportion to the act. They frequently act under delusions, which, if real, would be sufficient reason for their conduct if they were sane. Others act without motives. They feel impelled to their strange conduct by forces which they cannot resist or control. "These," says Esquirol, "act without consciousness, without passion, delusion or motive."\* "Such is the power of this disorder, that persons of the sweetest temper are driven to violate laws the most sacred, and kill those who are the dearest to them. Deprived of reason, they are influenced by no passion and no motive."† He mentions seven cases of this motiveless momentary insanity.

Tuke describes and quotes thirty-one cases of homicide, violence, or propensity, which he arranges in a class, under the descriptive head of "without marked disorder of intellect," and without premeditation and design.‡ Some, like the Suabian teamster before quoted, yield blindly to their excited destructive propensity and attack, injure, or destroy whatever or whoever may be in their way.

#### NO REMORSE AFTER CRIMINAL ACT.

Many of the insane, who commit acts of violence, murder, assaults, &c., under the influence of delusion, paroxysm, or impulse, when they regain their reason, do not feel that they were free agents nor responsible for their conduct at the time, as sane persons are. They may have killed those whom they most loved, wives, husbands, parents, children, and mourn their loss as deeply as they would the same event from any other cause. Yet ordinarily they feel none of the remorse that sane murderers would, none of the bitterness of self-condemnation.

Gall quotes a case of an insane woman who drowned her little son. "She behaved in the most regular manner, expressed the deepest repentance for the act, but did not consider it as a crime."§

Ray says, "The homicidal maniac, after gratifying his bloody desires, testifies neither remorse, nor repentance, nor satisfaction."\* A large part of the insane homicides and incendiaries described by the writers on these topics are said to have shown no remorse; and although they may have confessed the facts, and their agency in them, they did not charge them upon their consciences as sins.

A young incendiary, who had set three fires in a state of mania, was brought to my care. He coolly confessed his agency in these facts, and regretted it, but felt no pang of conscience.

Thus men who are even sensitively conscientious in regard to their conduct in health, commit atrocious acts in their insanity, and afterwards, when reason is restored to them, they charge themselves with no sin for these acts; they feel that they were not then responsible. Their calmness seems to those who do not understand the disease to be hardihood in crime, and is held by them as evidence of guilt, while the psychologist looks upon it as a proof of innocence and irresponsibility.

#### NO CONSCIOUSNESS DURING THE ACT, NOR RECOLLECTION AFTERWARDS.

Among the significant peculiarities connected with the violent acts in the paroxysms of some of the insane are unconsciousness during the act, or outbreak, and forgetfulness or absence of recollection afterwards. In these cases, the mind seems suspended and receives no impression, and, of course, retains none. Referring to the acts of a maniac in his brief paroxysm, in the trial of Rogers, Dr. Woodward said, "the memory of what has occurred is frequently obliterated;"† and Dr. Bell, "in cases of outbreak the impulse is so sudden that the patient is hardly conscious of his acts. It often occurs that after the paroxysm has ceased the patient has little or no recollection of the act itself, though he remembers pretty well what preceded and what followed.‡

The young man who attacked the advocate in the court room of Paris already described, had no consciousness of the act at the time, and no recollection afterwards.

Dr. Laycock, the learned Professor of Medical Psychology in the University of Edinburgh, in a lecture on the legal responsibility of the insane, quoting the case of Bryce, who had killed a person, but had no recollection of it, said, "want of recollec-

† *Trial of Rogers*, p. 161.

‡ *Ibid.*, p. 157.

tion is common in homicidal lunatics of a certain class."\*

Dr. Ray, in trial of Rogers, said "where the paroxysm of insanity is very severe and the conduct of the patient very violent, I have generally found a breach of consciousness in his mind. He appears to have lost a portion of time out of his recollection. I have always inquired of patients in regard to the degree of their consciousness, and I cannot think of a single instance where one was conscious of everything during the paroxysm."† Dr. Ray, in his *Medical Jurisprudence of Insanity*,‡ a work of the highest authority in America and Great Britain, quotes the instance of a girl who, in a paroxysm, was violent, sometimes attempting her own life and sometimes that of her mother. The fit, which, altogether, continued one or two days, being over, she recovered her affection for her mother, and asked her forgiveness. She did not recollect all the circumstances of these fits, and denied, with feelings of surprise and regret, some of the particulars which were related to her."

Castelnau gives several cases of similar forgetfulness of the events of a paroxysm of mania. The shoemaker who suddenly attacked his wife,§ the man in Rue de la Porte d'Alais, in Paris, who was suddenly made insane, and broke his furniture, and abused his wife;|| the woman who grossly insulted her companions in an outbreak,\*\* all these severally had no memory after the restoration, of what they had done in their insane excitement. So also the tailor, whose case he quotes from Marc, De la Folie, ii. 512, who suddenly became insane, and began to overturn furniture and attacked his wife, had the same unconsciousness of his acts at the time, and the same want of recollection the next day.††

Baron Martin, presiding at the trial of Townley, for the murder of Miss Goodwin, at Derby assizes, December, 1863, in his charge to the jury, said, "In one species of insanity, the patient lost his mind altogether, and had nothing left. Such a person would destroy his fellow-creatures as a tiger would his prey, by instinct only; a man in that state had no mind at all, and therefore was not criminally responsible."‡‡

A boy under my care as a patient was ordinarily as quiet as other and sound persons. One night he refused to go to bed at

his usual time and in his usual way. I endeavored to persuade him, and not succeeding, I took his hand to lead him to his chamber. Immediately he broke out in furious rage, and for three quarters of an hour he tried, in all ways and means, to injure me, and the persons and things about him, to bite, strike, kick, scratch, overturn furniture, books, &c. At the end of this time he became quiet, apparently exhausted, and fell asleep in my lap. We then put him to bed. All this time he seemed utterly unconscious, and to be governed merely by instinct. The next day he had no recollection of the events of the evening. He was languid and feeble, as if he had passed through great excitement or labor; but after this, he had no more paroxysms, nor, in the four or five years succeeding, during which I knew of his condition, did he have any further mental disturbance.

#### INSTRUMENTS OF INJURY.

A sane man, whether honest or criminal, when he has an object in view, a purpose which he premeditates and plans to accomplish, usually prepares in advance the means fitted for his object, and obtains the best instruments within his knowledge or reach. The insane, under homicidal delusions or propensities, sometimes make such preparations, and obtain arms, guns, pistols, knives, razors, which they use for their destructive purpose. But when the paroxysm is sudden, and the propensity to kill or injure comes after or with the outbreak, then he seizes whatever may be within his reach at that moment and place.

"The criminal lays his plan for the execution of his designs. Time, place and weapons are all suited to his purpose. The homicidal monomaniac, on the contrary, for the most part, consults none of the usual conveniences of crime. He falls upon the object of his fury, oftentimes, without the most proper means for accomplishing his purpose."\*

One of Dr. Woodward's homicidal patients was standing before his fireplace, by the side of his wife. He was suddenly excited with mania, then took the andiron which was then present, and with it struck his wife a fatal blow.† Another, in the same mental state, took a billet of wood that lay before him, and used it with the same deadly effect.‡

Dr. Ray quotes a case from Georget (*Discourse Medico-Legale*, 153) of an epileptic, who, in a paroxysm, ran through the fields;

he pelted one man with stones, which he threw at him; he knocked down another by beating him on the head with a large stone in his hand; he attacked a third with a spade which he found in the field, and a fourth with stones.\*

Esquirol gives account of a woman who killed her child, stabbing it twenty-one times with scissors.†

Castelnau speaks of one who did a similar work with a pocket-knife.‡

An epileptic patient under my care, was disposed to fight in his sudden outbreaks. Then he would use whatever means happened to be before him. In the house he took up books, chairs, inkstands. When walking in the fields with his attendant, he took up stones to throw at him, and once he used them as mallets in his hands to beat his companion.

(To be continued.)

# THE PHYSIOLOGICAL AND THERAPEUTIC RELATIONSHIPS OF ERGOT OF RYE.\*

A Thesis for the Degree of Doctor of Medicine; and to which was awarded the First Prize of the Boylston Medical Society for 1869.

By FRANK W. DRAPER, M.D.

(Continued from page 312.)

It concerns us now, from this review of the physiological symptoms of the action of spurred rye, to draw some inferences concerning its *modus operandi* in the system. On this deeply interesting question many and very varied opinions have been expressed, each observer arriving at conclusions oftentimes quite at variance with those of his predecessor. Thus the earliest authors claimed that all the effects of ergot, whether manifested in the uterine or in the nervous systems, were due to the presence of a poison in the blood, and to the efforts to eliminate it. Wright classes the drug as a "narcotico-acrid" agent, whose effects are due to its secondary depressing or sedative influence. Certain French authorities, of acknowledged repute, regard it as a stimulant and excitant, and illustrate their theory thus:—"If, under the influence of ergot, feeling and motion are observed to return to limbs previously paralyzed, we should not be inclined to call in question its power as a stimulant on the spinal cord." (*Bibliothèque du Med. Pract.* p. 230.) Parola and the Italian school of observers insist that the varied physiological and therapeutic effects may all be referred to a general hyposthenic influence on the whole

circulatory system, and make it the analogue of bloodletting and tartarized antimony. Thus, in parturition, ergot favors uterine contraction by acting on the engorged vessels of the uterus; these vessels having been depressed by the "hyposthenic" action of ergot, the organ is no longer confined by their state of excessive congestion, and can contract freely and accomplish its function. Again, Headland, an authority of universally acknowledged weight, says of this agent that "it is a stimulant to the muscular nerves of the uterus of the female, but to no other nerves in marked degree"; and, in another connection, when speaking of its effects in an overdose to produce "sometimes syncope, and sometimes narcotism," he says, "this is not the office for which it is employed, and is altogether distinct from its operation as a special stimulant, which is exerted only on the ganglionic nerves of the muscular uterine." In small doses it produces no other effect, and thus its action is purely and wholly local in its nature.—(Action of Medicines, p. 262.) So late as 1863, a writer in one of the British medical journals claimed that the specific action of spurred rye in producing uterine contractions was due to its nauseant effect; and he had observed that other depressant emetics, as tartarized antimony and ipecac, produced similar results, while, on the other hand, in cases where vomiting was absent after the administration of ergot, the uterine inertia remained *in statu quo*. Within the past year, a contributor to the *American Journal of the Medical Sciences* has urged ergot as an efficacious remedy in neuralgia, basing his theory on the premise that the physiological effect of the *secale cornutum* was to stimulate the vaso-motor nerves; and presuming neuralgia to consist of a disordered nutrition, "a cry of the nerve for healthy blood," the existing condition would be thus effectually counteracted.

But on a careful analysis of the various symptoms which follow the exhibition of ergot, it does not appear that any of these theories offer a full and satisfactory explanation of all the phenomena. Each one has its features of apparent plausibility, but when applied to the test of a systematic analysis of the phenomena produced, it is found to be wanting in essential points. But it seems to have been reserved for our own day, and we may almost say, for our own country, to witness the discovery of the true mode of action of ergot, and to Prof. Brown-Séquard belongs the distinction of first clearly demonstrating the theory

\* *Med. Jurisprud. Ins.*, p. 209.

† *Malad. Ment.* i. p. 231. ‡ *Ann. Hyg.*, xlv. p. 439.

which satisfactorily accounts for all the varied, and sometimes apparently heterogeneous, physiological and therapeutical powers. His view may be presented in the following proposition:—*Ergot is a special stimulant of the unstriated or involuntary muscular fibre wherever it is found.*

Before discussing the truth of this proposition, it may be well to look for a moment at the nature and distribution of the anatomical tissue, the muscular fibre of organic life, which is said to play so important a part in the action of ergot on the economy. According to Wilson (Human Anatomy, p. 171) "the ultimate fibre of organic life or smooth muscular fibre, is a single homogeneous filament, much smaller than the fibre of animal life, flat, smooth, and without transverse striae. It is distributed abundantly in the animal frame, and is met with where a distinct contractile power, independent of mere elasticity, is required; as follows:—in the alimentary canal, from the middle of the œsophagus to the internal sphincter ani; in the posterior segment of the trachea, and in the bronchial tubes to their finest ramifications; in the excretory ducts of the various glands; in the ureters, bladder, and urethra; in the uterus, vagina and Fallopian tubes; in the middle coat of the arteries, veins, and lymphatic vessels; in the iris and in the corium of the skin."

Here, then, we have a tissue endowed with contractile power to a high degree, and distributed very generally through the system. Any agent possessing the power of affecting this in any degree must create, directly or indirectly, symptoms in great number and diversity, and in endeavoring to apply the test to ergot, to draw the analogy between the various phenomena presented by the artificial influence of this agent, and those consequent on certain pathological conditions, we are bewildered by many collateral questions which seem to extend investigations indefinitely. We can only examine briefly some of the more evident relations, and attempt to analyze the phenomena of the action of ergot on the system in their application to the proposition of its general physiological action.

If a proper dose of *secale cornutum* be taken, it is absorbed and enters the blood directly; with that fluid it circulates to all parts, reaching in its course every organ, and extending its influence to the smallest artery. These minute vessels contain, as their middle coat, a layer of organic muscular fibre, readily obnoxious to stimuli. The first and more obvious effect of stimulation of the circular fibres, is a contraction

and diminution of the calibre of the vessel. Virchow has shown that this contraction may, under certain circumstances, proceed until the canal is almost entirely obliterated. (Cellular Pathology, p. 147.) The legitimate consequence of this is, necessarily, a temporary anæmia. Now ergot, presenting itself throughout the body, to all the arterial ramifications, performs, through its active principle, this stimulant function. This action, with its resultant effects, has been demonstrated by experiments on animals, Brown-Séquard having "repeatedly seen the diminution of the calibre of the blood-vessels of the pia mater of the spinal cord, taking place in dogs after they had taken large doses of ergot. (Braithwaite's *Rel.* 1861, p. 39.)

In view of this theory of general anæmia as one effect of ergot, it becomes an important question to determine what becomes of the blood in such cases, its total quantity remaining the same in the body. There is but one apparent reservoir for this back flow, and that is found in situations where the muscular fibre is less abundant, and hence a venous congestion results. Wright includes among his observations, reports of *post-mortem* appearances in animals dead from the effects of ergot, and in these he says of the condition of the lungs, that "they were much darker than usual, and their surface exhibited various ecchymoses, not the consequence of gravitation from position, but apparently resulting from stagnation of the blood during life." (Op. cit.) The heart, too, in these instances was generally found distended with blood. In support of this proposition, also, the fact is stated that in fatal cases of ergotism, "the parenchymatous organs were found congested." (Stillé—Op. cit. p. 588.)

Of the physical appearances depending on the anæmia of ergotism, perhaps the most obvious is the general pallor or lividity of surface which various authors have noticed as a constant symptom. This, of course, offers the most apparent external indication of the diminished supply of blood to the surface, and, as an almost necessary concomitant, a diminution of the temperature has been observed in many cases, both in man and in animals.

In the brain, the anæmia of ergotism gives rise to symptoms so exactly analogous with those of cerebral anæmia, when recognized as a pathological condition, that it will be interesting to enumerate and compare them, as reported in each case by different authors. Gubler notes the following among the signs of acute ergotism; depend-

ing, as he says, on "the sole property of ergot to convulse the contractile elements:" nausea and vomiting, numbness, lassitude, heaviness of the head, vertigo, dilatation of the pupils, delirium, stupor, sedation of the circulation" (Op. cit. p. 113). Assymptoms, on the other hand, of cerebral anæmia, whether depending on the general constitutional condition, or produced artificially by compression of the carotids, hæmorrhage or otherwise, Handfield Jones recognized "loss of consciousness, dilated pupil, vomiting, dizziness, swooning and coma, with depression of the circulation." (Functional Nervous Disorders, p. 48.) This comparison shows such an obvious similarity as to readily suggest the necessary inference.

The sedation to the circulation, which at first view might appear susceptible of an explanation on mechanical grounds, or perhaps by the direct action of ergot on the inorganic muscular elements of the heart, or indirectly by the temporary compromise of its nutrition, is fully accounted for by the anæmia of the brain, which seems to produce this derangement of the circulation as a constant symptom, analogous with that caused by sudden shock, excessive hæmorrhage and other such conditions.

Upon the spinal cord, also, the effects are no less decided, while the analogy, pointed out above in the case of the brain, is equally obvious. Handfield Jones (Op. cit. p. 61) records, as the result of ligation of the aorta in animals, a slowness of respiration and gradually developed, and, finally, complete paraplegia. Convulsions were the exception, thus establishing a distinction between anæmia of the cord and that of the brain. This condition of the cord is deemed by this author a rare affection, and only a single case is cited. In this, the patient was seized with numbness running down the legs, and with retention of urine. To this there soon succeeded a paralysis of the lower extremities, involving both motion and sensation. Consciousness was perfect. Under tonic treatment, this condition shortly yielded, and in a little more than a month the patient was well.

Among the effects of the cumulative action of spurred rye on animals, Wright found that one of the most constant was a weakness of the hinder extremities, soon developing into paralysis. This condition, taken in connection with the diminished respiration which has been repeatedly remarked, suggests at once a similarity with the functional state just noticed. It is true that in the human system the cumulative

influence of ergot has not been observed to produce these grave symptoms of impaired nervous power, but it would seem that an approximation to that state is found in the numbness and itching of the skin which have been recorded as symptoms of ergotism.

The power of ergot to directly stimulate, and to contract the muscular fibre of the intestines and of the trachea and bronchial tubes, is at best a question for further investigation. No special experiments appear to have been made in this direction. There are, however, a few detached phenomena which seem to afford some light in the matter; for example, Wright, in his numerous experiments, repeatedly observed in animals, dead from ergot, distinct contractions encircling the intestines like bands, while their general calibre was markedly diminished. The "abdominal pains and alvine evacuations" mentioned by Gubler as among the effects of ergotism, point also to the increased muscular action in the intestine, by which the normal vermicular motion is exaggerated. The dilatation of the pupils may be due both to the direct effect of the drug on the involuntary muscle which composes the curtain of the iris and to the anæmic condition of the brain, as remarked upon before. Again, the state called "goose-flesh," often seen in ergotism, may perhaps be attributed to the stimulation of the delicate involuntary muscles, the *arrectores pilorum*, which lie imbedded in the corium, causing a condition like that from the impression of cold.

The effect of ergot on the uterus was the influence which first procured for that agent a place in the *materia medica* as a remedial agent of the first order. Its power to originate uterine contractions, as well as to intensify those already commenced, is too well known and too generally recognized to need elaborate vindication.

The phenomena of this effect are well defined by Gubler as follows:—"The uterus being the seat of election of the action of ergot, if the organ is gravid, tonic contractions, more or less marked and prolonged, are induced, under the influence of which the viscus assumes a very decided hardness and a globular form, like the condition during the spontaneous pains of labor. These spasms, artificially produced, are like the intermittent normal contractions accompanied by painful sensations, known as uterine colic. They are sufficiently powerful to hasten the expulsion of the fetus. Besides pregnancy, and the hypertrophy of its contractile tissue, the

uterus feels the influence of ergot proportionally to the development of its special muscular apparatus. This effect is seen in the hypogastric pains and by the discharge of blood, as well as by the suspension of metrorrhagia." (Op. cit. p. 113.) The nature of this action is composite. If the uterus is in its normal, unimpregnated state, its tissue is composed of the unstriped muscle largely supplied with bloodvessels. This special anatomical structure is emphatically exaggerated when the organ is undergoing its peculiar functional changes in pregnancy; the muscular substance is then greatly hypertrophied, while the circulatory apparatus is proportionally augmented. Such a condition renders the uterus, which at any time attracts to itself the elective action of ergot, more readily susceptible to its influence, the special effect manifesting itself alike on the smooth fibres of the uterine walls, and on the smooth fibres of the contained bloodvessels, on identically the same principle.

A series of symptoms, which together characterize an epidemic affection almost unknown in this country, but common enough on the continent of Europe, still further illustrates the cumulative effects of ergot. From the time when, at the close of the eleventh century, Sigebert de Grenblour first recognized the cause of this disease and described its symptoms, until the present, ergotism has been identified as the legitimate consequence of the continued use of the diseased rye as an article of diet. The uniformly devastating effects of this ergotized diet have been repeatedly recorded; whole districts have been infected as by a pestilence, armies have been decimated, the sexes have suffered alike, and in every case the cause was attributed to the diseased rye. The symptoms of this peculiar, and, in general, fatal affection are so characteristic and so clearly exemplify the legitimate physiological effect when carried to its extreme degree, that we can do no better than to transcribe two cases illustrating the two recognized varieties of ergotism, the spasmodic and the gangrenous. "In 1841, a family of eight persons lived upon heavily ergotized rye-bread, the grain having been gathered during the preceding wet season. The chief symptoms consequent were these:—Malaise, anxiety, exhaustion, fainting, coldness of the whole body, a sharp, pricking pain and formication, numbness of the hands and afterwards of the arms, alternating with spasms so severe as to extort tears. The muscles of the lower extremities were affected in the same manner, and, in one

case, those of the right side of the face, and, subsequently, those of the abdomen were spasmodically contracted. About the sixth day, nausea, vomiting and diarrhoea took place, with severe pains in the bowels and bladder. At the fourteenth day, two of the children lay as if stupefied, or, if roused, raved wildly or complained of pain in the head and limbs. At the same time, a pruriginous eruption appeared on the skin. They died, on the twenty-first day, in violent convulsions. The other case is reported by Bonjean. Like the former, the family consisted of eight persons. Of these, four were not affected, two but slightly so, and of the other two, one perished and one lost his leg. All of them had lived on the same bread. In the fatal case, the symptoms were these:—pain in the groin, a dark spot on both calves, coldness and pain in the legs, followed by an eruption of vesicles, with violent itching, and, finally, gangrene of the lower third of the legs. The upper part of the legs was affected with humid gangrene. Both legs were amputated below the knee, with little loss of blood. No extension of the disease followed, but the patient died of pneumonia, which was probably metastatic. In the other child, but one leg was affected; its symptoms were the same as in the first case, but spontaneous separation of the limb took place at the knee, and recovery followed. (Stillé's Therapeutics, vol. ii. p. 589.)

So clearly allied is this train of symptoms with the phenomena of the action of ergot, experimentally demonstrated, that it is obviously but the exaggeration and culmination of those phenomena on the principle already stated—the power to contract the involuntary muscles. For example, the fatal gangrene which constitutes so important a feature, is but the necessary effect of the continued sedation to the circulation, in parts distant from the heart, and depends on the prolonged diminution of the calibre of the vessels. In this respect it resembles precisely the well recognized effects of cold, the compromise of the circulation resulting in a lesion of nutrition and a consequent death of the part, without inflammatory changes. So, again, the cramps, the convulsions, the coma, the formication, the abdominal symptoms and the coldness and numbness, illustrate in the most emphatic way the various phases which characterize the action of ergot on its proper underlying principle, and were there no other facts at hand, these phenomena would serve to demonstrate the theory that "however numerous and various these effects, they can,

nevertheless, be all referred to the fundamental action of ergot upon the nuclear fibres, and in general on the fibres or even the contractile granules of organic life." (Gubler.)

From this survey of the physiological action of ergot, one or two considerations must be evident almost at the outset. Upon the principle that this agent is a special stimulant of the involuntary muscular fibre, it may be properly asked why we do not observe, in its ordinary use, phenomena characteristic of its general constitutional effect; if its powers are so great to contract fibre in one part, why is its action limited or neutral in others equally well supplied with involuntary muscle; if the uterine and the vessels of the spinal cord are readily acted on, why do we fail to detect equivalent effects at the same time in the bladder, the intestines, the iris, the œsophagus? Without admitting that the action of spurred rye is so absolutely limited, or that all the involuntary muscle in every part fails to feel in some degree the effect in any case, it must be confessed that the action is elective in very considerable measure. It has been recognized from the earliest times in the history of ergot, that the uterus was especially sensitive to its impressions, and hence its traditional synonyms:—*mutterkorn*, *pulvis partum accelerans*, *pulvis parturificiens*. The reason of this partiality is found in the accepted dogma of elective affinity in medicinal agents—the special power of affecting certain parts or organs to the exclusion, partially or wholly, of others. Just as certain cathartics select, for their field of action, their own appropriate portions of the intestinal tract, to the exclusion of the rest; just as strychnia manifests its peculiar power through the spinal cord, leaving other portions of the nervous system; just as diuretics owe their special effects to their special attraction toward the renal apparatus in the process of elimination; so ergot exhibits its action by selecting its own proper field. The reason why, in epidemic ergotism, in the same season, and under similar conditions, different individuals are differently affected, one exhibiting all the symptoms of spasmodic ergotism, and another those of the gangrenous type, must be sought for in individual idiosyncrasy and aptitude for special tendencies.

The obvious analogy between the theoretical action of ergot and that of the class of drugs called astringents, would seem to indicate that the latter should include the former. Indeed, according to the theory

stated, there appears an almost absolute identity of action. But the difference lies in this. "Astringents," according to Headland, "act directly and especially on muscular fibre, causing it to contract, whether it be striped or voluntary, or of the unstriped and involuntary kind. This depends on their chemical power to coagulate albumen, and from this they derive their dynamical power over living tissues." But this power to coagulate albumen does not reside in ergot, nor does it appear to exert any influence over the voluntary muscular fibre. In these two important respects, then, ergot seems removed from the class of general astringents, while it may claim to be considered as a special astringent, whose powers are of a peculiar nature.

[To be continued.]

#### A CASE OF HERPES ZOSTER OPHTHALMICUS, IN A PATIENT 80 YEARS OF AGE, CAUSING FATAL PROSTRATION; WITH REMARKS.

By B. JOY JEFFRIES, A.M., M.D., Ophthalmic Surgeon  
Mass. Char. Eye and Ear Infirmary, Boston, &c. &c.

(Concluded from page 319.)

SEVERAL cases have lately been reported where paralysis accompanied herpes zoster. Dr. F. B. Greenough, Boston Medical and Surgical Journal, p. 401, 1868; Dr. Albion Cobb, same Journal, p. 95, 1869; Mr. B. J. Vernon, *St. Bartholomew's Hospital Reports*, vol. iv., 1862, and Dr. John Duncan, Oct., 1868, *Journal of Cutaneous Medicine*. This has occurred too often to be treated as a mere coincidence, and must be taken in due consideration in the study of the pathology of this disease. Hutchinson's remark seems to grow more and more applicable, "that whoever succeeds in unravelling the mystery which at present surrounds it must at the same time make a discovery in physiology."

Dr. Edward Woakes, in the *Journal of Cutaneous Medicine* for October, 1867, published some remarks on the correlation of cutaneous exanthemata with neuralgia, analyzing Mr. Paget's observations, and those of our countrymen, Drs. Mitchell, Moorhouse and Keen, on wounded nerves. His theory, as applicable both to the traumatic and idiopathic forms of this disease, is—"that, owing to the suspension of the regulating power exercised mainly by the sympathetic nerves over a given artery, effusion takes place from its ultimate ramifications. These being distributed to the skin on the one hand, and to the texture of the

sensory nerves on the other, the effusion so caused produces the herpetic rash in the former, and pain from mechanical pressure in the latter." This theory, as explained in his article, is certainly a very plausible one, and best harmonizes with the results of observations. All theory, however, in reference to herpes zoster, whether traumatic or idiopathic, is at present perhaps premature, and any one founded on a few cases seen in the practice of a single individual, is most likely to be subsequently disproved. Herpes zoster still remains a nosological riddle.

In regard to the special form of *ophthalmic* herpes zoster, if we may draw conclusions from the above table of thirty-four and the other cases reported, we can say that it may affect the frontal branch alone, or the frontal with one or more of the others. It does not seem to affect the other branches *without* the frontal. The eye is not affected when the frontal alone is involved. The danger to this latter organ is very great, as it has at times been destroyed or useful vision taken from it. Mr. Hutchinson says:—"I have seen several cases in which the cornea, sclerotic and iris became involved in inflammation. As a rule, I think the eye does not inflame until the eruption is at its height or already beginning to decline. In one case, however, a single nodule of lymph near to the pupillary edge showed itself in the early stage, and without any ulceration of the cornea. More usually the ulceration of the cornea is extensive, and often it prevents a satisfactory inspection of the state of the iris. There is always great congestion, both of conjunctiva and sclerotic, and this congestion, as well as the corneal ulceration, is very slow in disappearance. The pupil, even when there is not much lymph visible, is always very sluggish, and in several cases I have found it impossible to make the iris act by atropine, even by strong solutions frequently repeated. I have never seen hypopyon in connection with this form of ophthalmia, nor does the other eye seem to suffer. According to my experience, herpes zoster frontalis is more frequent in the aged than in the young, and also more severe. The liability of the eye to suffer also appears to be much greater in the old." "When the disease has subsided, the eyeball is usually left somewhat anæsthetic, though perhaps at the same time liable to neuralgic irritations: In this it shares with the skin, ing with although perhaps very painful, is The numb as regards common sensation. After the stages the patients often com-

plain that the skin feels 'numb and stiff like parchment.'" Mr. Bowman says:—"It is not always possible to examine the eye accurately during the herpetic attack, owing to the swelling of the lids; but when this subsides, it is usually easy to ascertain what tissues have suffered. I have seen nothing like herpetic eruption on the conjunctival surface of the lids or globe. The conjunctiva may be too red, the eye may be watery and intolerant of light, and the peculiar pain of the affection may be experienced in, or referred to, the organ itself; but usually there is no primary disease, such as corneal or iritic inflammation, coincident with, or forming a part of the eruptive stage of the complaint. If these occur, they seem rather to follow after a short interval. Small softening or ulcerations of the cornea, rather marginal than central, and slight iritis, are the more common complications, but rather the former than the latter; and they have seemed to me to bear considerable resemblance to those following smallpox, both in their course and the treatment they demand."

I avoid further speculation on this form of the disease in our present knowledge of it. Mr. Hutchinson says:—"There can be little doubt that the local processes of inflammation in the skin and the eye are produced directly through the medium of the nerve, in this instance, of the ophthalmic division of the fifth (some or all its branches). At what part of the nervous system the irritation begins, however, we are quite in the dark. I can see no arguments in favor of the belief that it is produced by the vaso-motor rather than by the sensory trunks. It appears always to follow accurately the distribution of the latter." "This singling out of one particular nerve-branch might seem to imply that the irritation, whatever it is, attacks the nerve-trunks after their subdivision. It is possible that it may be brought to bear upon them through the medium of the vaso-motor ganglia. This conjecture is very different from the one which would attribute the whole production and localization of the disease to vaso-motor filaments. Other arguments might be held to support the conjecture that the irritation starts from the cerebral ganglia of origin for the nerve concerned." "I must beg to warn against hasty inference, from the fact that sometimes only one branch of the ophthalmic nerve, and sometimes all are affected; that it is therefore probable that the disease commences in the nerve-trunks after subdivision, rather than in the cerebral or ganglionic centres com-

mon to them all. Such an inference is surely most unfounded. The nerve tubules which are to be distributed, as the 'frontal nerve,' for instance, are just as distinct from those constituting the nasal branch, when they are bound up in one bundle and called collectively the 'ophthalmic nerve,' as they are subsequently, when divided. There can be little doubt that, whatever may be their mutual relations for convenience of transit, they are perfectly distinct from one another from beginning to end. It is therefore easily comprehensible that a source of irritation, beginning either in the Gasserian ganglion or in the mesocephale itself, may be restricted in its influence to one branch only."

Dr. M. Singer records a case of herpes zoster following all three branches of the fifth, and in which it was observed that the two senses of touch and taste in the tongue disappeared and reappeared in strict unison, thus giving strong corroboration to the idea that the lingual is a nerve of taste, (*Biennial Retrospect of Medicine.*)

Dr. P. Gerhardt says that the group of diseases in the course of which zoster facialis is frequently observed is distinguished by the frequency of the initial rigor, or the occurrence of an increase of temperature to 30° Réaumur (104° F.) even on the first day. Gerhardt remarks that this affection does not attack the trunk or limbs, but only the face, and thinks that the irritation must be caused by the following peculiarity of the fifth nerve. The branches of this nerve run through narrow, long canals, along with small arteries; these arteries contract in the initial rigor, but then dilate, and their abnormal size creates a pressure on the branches of the trigeminus and the sympathetic. The occasional result of the damage to the latter is the occurrence of a vesicular eruption on the skin. He thinks that when this has once occurred an accommodation takes place, in virtue of which a second attack of febrile dilatation of the vessels does not irritate the vaso-motor fibres so as to cause the eruption. (*Biennial Retrospect of Medicine.*)

As regards treatment, Mr. Hutchinson says:—"Whilst our pathology is so uncertain, we can allege nothing with confidence. I have always been in the habit of ordering quinine, and using any simple local application which may seem most appropriate to the stage of the eruption. Lead lotion at first, or free applications of oil, or, if the pain be very severe, of laudanum, are all useful." Mr. Bowman says:—"I wish I

could state anything very satisfactory as to the treatment of the after-pains, which are sometimes so severe as to make the patient weary of existence. In Case IV., subcutaneous division of the nerve was only undertaken after almost all other remedies, local and general, had failed. It certainly for a time took away all feeling from the region to which the frontal nerve is distributed, and when touched in this region the patient no longer experienced the pains which previously tormented him. But in a few weeks the sensibility had returned, and even at first the pains in the neighboring parts to which the remedy had not extended seemed such as to make the partial relief very little appreciated. It may be also that the morbid condition of the nerve on which the pain depended was not confined to the part peripheral of the point of section, and that the central portion continued the seat of pain. Perhaps if it had been possible to divide the nerve further back, the relief would have been greater."

"In Case VI., very marked relief did follow section of the nerve, and with clear evidence of the fact. When the frontal nerve was divided, the frontal pain was greatly lessened. When the external nasal branch was cut, pain was no longer referred to the skin of the nose, while the inner surface of the nostril continued to be the seat of distressing pain, and I could think of no way of dividing the inner branch entering the nostril far back through the ethmoid. The relief, so far as it extended, was in this case so permanent and considerable as constantly to elicit the patient's thanks. The result in this case would incline me to recommend the division of the nerve, a very harmless proceeding under chloroform, whenever the after-pains are severe and continuous in spite of time and other treatment."

In the case I have related, as I have above said, division of the frontal nerve would not have been of special service till pain had left the parts supplied by the other branches of the ophthalmic, namely, upper lid, side of nose and eye. This it did not do till after the fourth week of the disease, when any operative interference would not have been tolerated by the patient.

Dr. Crépinel reports that he has found great benefit in the treatment of neuralgia in herpes zoster from the local application of chloroform and oil (one part to five), some five or six times daily. The proportion of chloroform to be increased when the pain is very severe; the remedy to be applied as early as possible in the disease.

I will finish with the following quotation from the *British Medical Journal*, vol. i., 1866, p. 470, as it applies to two cases in Mr. Hutchinson's table and to the plate published by the Sydenham Society:—

"A few months ago, at a meeting of the Council of the New Sydenham Society, the new plates of the series of skin diseases were presented to the Council for approval. One of these plates, representing a specimen of herpes zoster of the head and face, excited a little amusement among some of the members. 'Who had ever seen the disease in such a part? Surely it was unnecessary to depict so rare and far-fetched a complaint.' Curiously enough, one of the Council, Dr. Markham, who had had his joke on the occasion, was himself last week pronounced, by his friend Dr. Stewart (another of the unbelieving ones), to be 'a splendid specimen of that very disease we were joking about a few months ago at the Council of the Sydenham Society.' Herpes zoster of the head and face is, however, no joke to the patient. A man need wish his worst enemy no worse week's or fourteen days' excitement than that of an attack by it. In the present case the disease was limited to the course of distribution of the left supra-orbital nerve, and showed, throughout, its distinctive nerve character. Five days before the eruption appeared there was constant neuralgia of the aforesaid nerve and hemicrania. Considerable itching and several hardish and painful subcutaneous elevations preceded the vesicular eruption. The eruption was markedly limited to the left side of the forehead and head and the root of the nose, and to the left upper eyelid."

I have given this somewhat lengthy compilation in regard to herpes zoster, and especially the ophthalmic form of it, partly in defence of my diagnosis of the case I record, but principally as it interested me in the two specialties I practise. I desired, also, to call the attention of the profession to it and prevent its being, as has no doubt occurred, mistaken for erysipelas. I regret my case could not be recorded in more detail; I think, however, it is sufficiently so to establish its identity. In reporting the case at the Suffolk District Medical Society, Boston, and the American Ophthalmological Society at Newport, I exhibited plates from Mr. Erasmus Wilson's series and portraits from Drs. Boeck and Danielssen, Prof. F. Hebra, the New Sydenham Society, and Baresprung and Hebra's Atlas, wood-cuts and photographs in the Ophthalmic Hospital Reports, and Reports of

the Charity Hospital of Berlin, and would refer to them. I append a list of the journal articles and monographs I have spoken of in the course of this paper.

## Bibliographical Notices.

*On Long, Short, and Weak Sight, and their Treatment by the Scientific Use of Spectacles.* By J. SOELBERG WELLS, Professor of Ophthalmology in King's College, London, &c. Philadelphia: Lindsay and Blakiston. 1869.

This is a third and enlarged edition of a work first published several years since. It is in great measure comprehended in the larger work on diseases of the eye by the same author, already reviewed for this JOURNAL. Further comment is unnecessary, except perhaps an allusion to the exquisite typography of the book itself.

"I have already insisted," says Mr. Wells, "upon the necessity of the surgeon himself determining the number of the glass which the patient is to wear, and not entrusting this to the optician." This is the text on which the work before us is an extended comment, the proposition of which it is the demonstration. On no portion of the medical field is quackery more rampant or its results more apparent. Peddlers of

spectacles infest country towns; and city newspapers display unblushing advertisements of glasses warranted to suit any sight, and to last twenty-five or more years. Books like the present are the best means of staying the progress of such rascality, and modifying the credulity on which it feeds.

## Medical and Surgical Journal.

BOSTON: THURSDAY, JUNE 10, 1869.

### RAPID CHANGE OF COLOR IN HUMAN HAIRS.\*

DR. BROWN-SÉQUARD, in the last number of his *Archives de Physiologie*, gives an account of a rapid change of color—from black to white—which took place in the hairs upon the face of the *savant* himself.

In the month of August, 1862, he began to notice the appearance of a few white hairs in the anterior portion of the beard covering the middle of both cheeks. The posterior portion had, already, for several years been sprinkled with gray, the anterior half remaining untouched. In this anterior portion, he, on rising one morning, found a few white hairs, which he extirpated. Two days after, in the midst of hairs which were black, or dark brown, in their entire length, with a few others which were white only near their roots, he found three hairs which were white in their entire length on the right cheek, and two on the left.

To make sure that he had not been mistaken, he followed up his observations on several occasions for six or seven weeks; and after each extirpation he saw black hairs become white throughout their entire length in the course of from two to five days. He remarks that it is scarcely necessary to say that, during the same period, a number of hairs began to whiten in the neighborhood of their roots.

Dr. Brown-Séquard was then in his ordinary state of health, and was not under any extraordinary mental influences. Thus, without any appreciable cause, he says,

than that which at a certain age makes the beard turn white, there took place in his case, a very rapid change of color, from black to white, in a considerable number of the hairs upon his face. As far as he could ascertain, this change occurred always in the night. He did not examine the whitened hairs with the microscope.

He concludes that this experience of his puts beyond a doubt the possibility of a very rapid transformation (probably in less than a night) of black hairs into white. He, however, considers that the statements on record of a sudden blanching of a considerable portion—greater or less—of the hair or beard do not rest on a basis of scientific authority.

IN one of last year's numbers of the *Archives de Physiologie*, we have been shown an article by Dr. Brown-Séquard on the subject of the *immediate arrest of convulsions of the lower limbs, by the irritation of certain sensitive nerves*. The Doctor had observed seven cases in which convulsions had been stopped by the means here indicated. The process consisted in simply flexing suddenly and with a good deal of force the great toe upon the foot. The first of his cases was a violent one. The cessation was prompt upon the application of the remedy, and lasted long enough for the patient to be dressed. This patient was seen in consultation by Nélaton and Trouseau, who witnessed the phenomenon. In some of the other cases the arrest of spasm was not so immediate or so complete; but in all seven there was at least considerable diminution of convulsive action, and that diminution was sufficiently prompt. Dr. Brown-Séquard makes some physiological reflections on these facts.

CONNECTICUT, May, 1869.

MR. EDITOR:—I send you an extract from the "*British Medical Journal*," "being the Journal of the British Medical Association," for publication in the BOSTON MEDICAL AND SURGICAL JOURNAL. It concerns the condition and position of our medical brethren in our Navy. I have recently been very intimate with two of them, very fine fellows, who feel that their state on board ship is little better than slavery. Doubtless you

\* *Poils* is the word used, meaning hair other than that which grows upon the scalp.

have seen the statements which they have recently put forth.\* One of the above to whom I have referred, and who is quite active in bringing the matter before Congress and the community, has just been displaced from a ship lying in our harbor on home duty, and sent to sea—a proceeding almost unknown in the Navy. But I have time only to say that the Surgeons of the Navy are anxious that the community should understand how much the service is likely to suffer from the withdrawal of the best talent in the Navy, and also to influence the minds of members of Congress, so that if the subject should come up again, they may be able to act understandingly. I am sorry Admiral Porter is said to be the prime mover in this injustice towards our profession.

SEXEX.

[From the British Medical Journal, April 24, 1869.]

"*The Naval Medical Service of the United States.*—From papers received by a member of our Association, we learn that there is urgent necessity for reform, in the Medical Department of the United States Navy. "*Corum non animus mutant, qui trans mare currunt.*" Combatant officers, all the world over, appear to be unduly jealous of the prerogative of *command*, and they repress the civilians associated with them, as a result of this unworthy feeling. It is evident that the matter is not viewed by them dispassionately, in consequence of the judgment being clouded by feeling. Usurpation of command on the part of civilian officers is impossible, and the commander knows and feels that he may hang any man, or officer, on board his ship at his own will and command, despite consequences, *for he possesses the power.* We should imagine that this reflection would be consolatory to the combatant class, and would enable them to repose majestically in the consciousness of power, without resorting to vexations and petty acts of restriction. The surgeons of the United States Navy are also dissatisfied, and, we think, justly so, with the treatment accorded to them by their Government; for, at the conclusion of the civil war, they were left unrewarded for their exertions (which were acknowledged to be valuable), whilst promotion and appointments were bestowed on the executive class. Patriotic feelings induce surgeons to serve their country during periods of war; but in time of peace there is disinclination for service, arising out of similar causes in both the American and British navies:—namely, neglect and re-

pression of the civil element of the service. As an illustration of this statement, it may be mentioned, that, in the year 1864, when the demand for medical men was at its height, "one hundred and thirty-two physicians declined appointments in the Medical Department of the Navy, alleging that they were willing to serve, as a matter of principle, or duty, during the war, but desired no *permanent* place in the navy." This is an unmistakable *pronunciamento* of the profession against the regulations and usages under which doctors are constrained to live, when employed in the sea-service; and, since at the present time there are fifty vacancies, notwithstanding ample opportunity of admission by means of an examining board in perpetual session, we may conclude that some radical change is necessary to maintain the efficiency of the United States Navy in time of peace.

"Farragut, like Nelson and other worthies of the British Navy, fully appreciates the claims of the surgeon to position and emolument, but inferior minds dread loss of dignity to themselves by the elevation of civilians. The surgeons ask for inspector-grades similar to those existing in European navies, especially as the rank of admiral has been introduced into the United States Navy; and they further ask that rank shall be substantive, and accompanied by privileges; always excepting *command*. It is a remarkable circumstance that the Navy suffers much more than the Army from a marinet spirit, which the executive officers term, *aristocratic*—we should rather say "*pseudo-aristocratic*." We wish our American brethren early and complete redress of their grievances; and we entertain no doubt of success, so long as they contend for it, by the weapons now in use by them—viz., discussion and congressional action. The American Medical Association has accepted the cause as their own, thus showing identity of feeling and of purpose with the British Medical Association, and the event cannot fail to be fortunate."

ANNUAL MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY. (*Continued.*)—To the account we gave last week of the first day's proceedings, we add the following.

Many of the Fellows visited the City Hospital on Tuesday morning, and at 11 o'clock witnessed the following operations:

1. Iridectomy, Dr. Williams.
2. Amputation of arm, Dr. Ropes.
3. Paracentesis thoracis, Dr. Bowditch.
4. Pharyngeal polypus, Dr. Chacever.

\* We have already published them.—Ed.

5. Iridectomy, Dr. Williams.
6. Glandular tumor of neck, Dr. Ropes.
7. Nasal polypus, Dr. Cheever.
8. Epithelioma, Dr. Ropes.

*Massachusetts General Hospital.*—After making the surgical visit in the wards, the members of the Society proceeded to the operating theatre.

A submaxillary tumor was removed by Dr. H. J. Bigelow. It was closely adherent everywhere, and was attached by a pedicle to the submaxillary gland deep behind the lower jaw.

Lithotomy was performed by Dr. Hodges on a boy eight years old; the existence of the stone having been known three years, and having occasioned great suffering. The lateral method was selected. The stone was large for a child of this age, weighing six drachms.

An epithelial cancer, of considerable size, was removed from the angle of the lip by Dr. H. G. Clark.

A large congenital erectile tumor of the cheek, of the size of a Chinese orange, was operated upon by Dr. Bigelow. The integuments were dissected up in order to preserve them for future covering, and the vascular mass was constricted by ligatures passed through the part subcutaneously.

Dr. Algernon Coolidge exhibited a case of severe and recent injury of the shoulder, which had just been admitted. Dr. Coolidge made some interesting remarks on the importance of accurate diagnosis in cases of this nature, dwelling especially upon the importance of anaesthesia previous to examination. After enumerating the various lesions which might be mistaken for the one which had occurred, he demonstrated the prominent features of the injury in the present case, and the method usually adopted in the Massachusetts General Hospital for its treatment.

Dr. Bigelow exhibited a severe case of cleft palate successfully operated on. The fissure extended through the soft and bony palate, separating the median incisors. By stripping the soft tissues from the bony roof of the mouth, after the method of Langenbeck, he had been enabled to close the fissure completely. Silver sutures and a hard rubber shield had been employed to assist cicatrization. Dr. Bigelow also exhibited the peculiar instruments used in this operation, including the gag by which the operation is now performed under ether and in young children.

Dr. B. also presented the case of extrophy of the bladder on which he had operated before the Society at its last annual

meeting. The extrophied mucous membrane, four inches in diameter, was now wholly covered with integument taken from the neighboring abdominal walls, and the urine escaped only by a linear opening upon the pubes less than an inch in length. The patient expressed himself as immeasurably benefited by the operation.

We give the above operation reports in the order in which we received them.

The following report of the Second Day's Proceedings we compile in part from the *Advertiser* and *Transcript*; but chiefly from the notes of the anniversary chairman, and those of some of the speakers at the dinner.

The credentials of the following delegates from other societies were presented:—Dr. G. E. Bickett, of Augusta, Maine; Dr. Wm. Swazey, of the Maine Medical Society; Dr. J. C. Hutchinson and Dr. James L. Little, from the New York State Medical Society.

Dr. Kimball, of Lowell, exhibited an ovarian tumor which had been successfully excised a day or two previously from a young woman aged 31. The peculiarity of the tumor consisted in its containing a rudimentary lower jaw with rudimentary teeth. The lining of the tumor was covered with osseous scales, the whole weighing twenty-five pounds.

This led to an interesting discussion on the subject of ovarian fetation, in which Dr. Burnham of Lowell, Jackson of Boston, Storer of Boston, and Perkins of Newburyport, took part.

Dr. David W. Cheever, of Boston, read a paper on the "excision of the entire diaphysis and the lower epiphysis of the tibia from a girl of 13 years, for suppurative periostitis, followed by regeneration of the bone, and a useful limb." The child was introduced to the audience, and the limb shown. Dr. Burnham, of Lowell, and several other gentlemen, presented cases.

A motion was made that the First By-Law be amended. A discussion which ensued was ruled out of order by the President, who stated that the rules and regulations required that the motion be referred to the Councillors, to be reported on at the next Annual Meeting. We believe the motion was finally withdrawn. At all events, the hour for hearing the oration having arrived, the delivery of that discourse took precedence of all other business.

The subject of the Annual Address, which was written by Dr. Alfred Hitchcock, of Fitchburg, was "The Organic and Parallel Relations of some of the Truths and Errors

of Christianity and of Medical Science." Dr. Hitchcock being prevented from delivering the discourse, procured the services of Mr. L. B. Munroe—Professor of Vocal Gymnastics in the Boston Public Schools—who read it for him.

*The Dinner.*—Shortly after 2 o'clock the annual dinner was served in Music Hall, where plates were laid, by J. B. Smith, the caterer, for about six hundred persons. In addition to the tables in the body of the hall, other tables were also placed on the platform. Dr. J. Baxter Upham, the anniversary chairman, presided, and Mr. Eugene Thayer officiated as organist. Both before and after dinner the organ performance of Mr. Thayer and singing by a choir of gentlemen gave a most agreeable diversity to the proceedings.

After the Society had become seated, the Chairman, J. Baxter Upham, M.D., introduced the Chaplain, Dr. Lothrop, of Boston, who invoked the Divine blessing, and after an organ voluntary, the Association and its invited guests proceeded to satisfy the wants of the inner man. The musical programme executed during the dinner comprised a German chorale by Luther, a transcription from Moses in Egypt by Rossini, a *morceau* from William Tell, and variations on "God Save the King," arranged by the organist.

At the conclusion of the repast the chairman—Dr. J. B. Upham, of Boston, addressed the Society as follows:—

*Gentlemen, Fellows of the Massachusetts Medical Society:*—In the name of my associates on the Committee of Arrangements, I extend to you all the hand of brotherly affection and of welcome. I congratulate you upon the return of this anniversary under circumstances so favorable and so auspicious. I rejoice that we are permitted to gather once more, in such large numbers, around these tables of social fellowship and good cheer—in this noble hall, whose tutelar deity is the patron both of music and of medicine, consecrated alike to art, to letters and to science.

You have come up again from all parts of this ancient Commonwealth, to exchange friendly greetings—to note the progress of the profession in this and other lands—to compare views and opinions on the great questions now uppermost in our realm of science—to hail with joy any new light that may have been shed along the pathway of truth—to give and to receive encouragement and counsel for the future—to pay tribute to the genius and learning of the liv-

ing and keep alive the memory of the honored dead.

Ours has been aptly called the quiet profession. It shuns the noise and tumult and strife of every-day existence; and, as a natural consequence, mostly loses the laurels that reward the common heroes in the great battle of life. It is the old story, so truthfully and touchingly told by Dr. Holmes, in words which deserve to be written on the walls of every hospital and school of medicine in the land—

"Two armies on the trampled shores,  
Two marshalled hosts are seen:

\* \* \* \* \*  
One marches to the drum-beat's roll,  
The wide-mouthed clarion's bray;  
One moves in silence by the stream,  
Along its front no sabres shine,  
Its banner bears the single line,  
'Our duty is to save.'"

The medical history of the past year, so far as our connection with it is concerned, may be very briefly told. I am not aware that it has been signalized by any novel or remarkable event. No wide-spread epidemic or new and dreaded form of disease has disturbed it. No deaths of very prominent and distinguished associates have saddened it. No startling discovery in physiological or pathological or therapeutical science, of which in other years we have had our full share, has set its seal upon it. We have gone on in the quiet and even tenor of our way, and the old Society, now nearing the completion of its first century of existence, is daily and nightly fulfilling its accustomed tasks.

Beyond these few words of negative allusion, therefore, I can find no excuse for detaining you with any remarks of my own. Accept, once more, my congratulations and the assurances of a sincere and hearty welcome.

The salutatory address concluded, the Chairman proceeded with the festivities of the day by introducing the following sentiment:—

"The prudent physician," says the old proverb, "is the keeper of his own counsel, thinking much, speaking little." Pre-eminently, such is he whom I have the honor to announce as the President of the Massachusetts Medical Society; of whom it may be said, as was once said of one of the greatest and best of men, "His merits are only equalled by his modesty." Allow me to introduce Dr. Charles G. Putnam.

The President responded as follows:—

The ardor of our chairman's address, gentlemen, has made it impossible for me

to add, by even one spark, to the warmth of his welcome.

I shall advert for a few moments to the changes in the times, and to the contrast which naturally suggests itself, between the more recent and the earlier anniversaries of our society. Formerly we met to discuss By-laws, listen to the Annual Address, and then, after the hastiest "plate of soup," rushed to the stage-coach or the "one horse shay"—some to plough the sands of Cape Cod—some to scale the hills of Berkshire. Now, thanks to science, and to the facilities of locomotion, we can enjoy for a while the companionship of our Fellows, and reap the fruits of their industry and learning.

Similar changes are everywhere in progress. The usages of Western civilization are gaining favor in the East. Theological questions in Europe are subjected to the test of individual criticism. Civil and religious liberty is promulgated in Spain and Austria, and the rights of manhood, delicately and adroitly hinted at in Paris, are more widely than ever asserted in England. "The resurrection of nations," says Lecky, is the miracle of our age.

The face of nature is changed by the union of distant seas—the mountain is no longer a barrier, the railroad through Mont Cenis, now within a few months of completion, will restore to Italy the ancient glories of Brundisium. The telegraph has neutralized the far-reaching enterprise of the monopolist—it has regulated supply and demand in trade, and is soon likely to do our familiar errands—"riding on the curled clouds" or "treading the ooze of the salt deep" with Puck or Ariel. Nor should we fail to notice the last great work of civilization—the railroad achievement that is to revolutionize the course of trade, and make Chicago—thirty years ago a frontier settlement—the great tea dépôt for the world.

In our national administration we hail the dawn of peace and prosperity, and the manifest desire to make truth and justice the corner-stone of the government. Let us hope to see it maintained with the same honesty of purpose in which it has been inaugurated. The effort, though somewhat thwarted, has already inspired refreshing trust, and, if even measurably successful, will exert a healthy influence, not merely in the arena of politics and in one city only, but in every class of society and over our whole land.

Our own science partakes of the same progress. The various appliances of natu-

ral philosophy—the more accurate and extended clinical observations—the wonderful researches of Séquard and Bernard into the properties and functions of the nervous system—the relations especially of the cerebro-spinal and vaso-motor nerves, have taught us greater certainty and discrimination in the diagnosis and treatment of disease.

J. Stuart Mill relates the story of Lord Mansfield's advice to a man of practical good sense who, having been appointed governor of a colony, had to preside in its courts of justice without previous judicial practice or legal education. The advice was to give his decision boldly, for it was sure to be right, but not to venture on assigning reasons, for they would infallibly be wrong." Nevertheless, in Law, Medicine or other vocation, he will be the better man who, all other things equal, is able to give a reason for the faith that is in him. "The knowledge that is insufficient for prediction may be most valuable for guidance," but safely as we may have been guided by observation and experience it is most desirable to ascertain the general principles applicable to our subject. In this view the recent application of Animal Chemistry is especially interesting, as it sustains, by its teachings, the practice learned from clinical experience.

It is most gratifying to be assured that not only have the pains been mitigated, but that the term of life has been extended by the art of Medicine. For instance, in his record of forty years' experience, Dr. J. C. B. Williams, of London, states that "the average duration of the life of consumptives has been at least quadrupled." In milder forms of consumption, under careful treatment, life may be prolonged for many years in comfort and usefulness, and in not very few, the disease may be permanently arrested."

Thus, directly or indirectly, by means of the light from so many sources, will general truths be discovered and a certainty attained, as absolute as the complexity and ever-varying conditions of the living body will permit. It remains for some one to collect and methodize these truths, and construct a science that will command the increased respect and subserve the best interests of the community. We would act our part in the cause of humanity with no exclusive system to maintain, no theoretical prejudice to warp the judgment, but with minds open to conviction to truth from every source.

In common with other avocations, the

practice of medicine has its share of annoyance from conceits, jests, and criticism. "The love of singularity," says Lecky, "the ambition to be thought intellectually superior to others"—these and countless other influences, all determine conclusions. As Meg Dods remarked of Lady Penelope Penfeather, "she had fallen ill as nae ither body had fallen ill, and sae she was to be cured as naeboddy was ever cured—whilk was nae mair than reasonable." So is it with Theology. One of the most profound and eloquent divines of the day, while urging the necessity of instruction in the fundamental principles of religion, goes on to say that "whenever unauthorized or crude novelties are broached under the name of religion, a full proportion of educated men and women, and of the so-called higher classes, are carried away by the folly."

To some of us the jests of Molière may be impertinent, and serious disparaging criticism is often undeserved, but there are cases, happily becoming less common, that justify the severest reprobation—cases in which polypharmacy is coupled with obtuseness, impenetrable as the shield of Ajax to any thrust short of the supernatural. Inasmuch as the truth we seek will be established by the conflict of opinion, we can tolerate—nay, more—we may be grateful for the satire of the playwright, the scepticism of the philosopher or the brilliant sallies of the poet.

It is not for us to teach ethics, nor is it worth while to array argument against a mere fabric of emotion—remembering the apothegm of Sydney Smith, that "what has not been reasoned *in*, cannot be reasoned *out*." It is our avocation to teach the means by which disease may be avoided, suffering lessened and life prolonged, and we may with reason congratulate ourselves on the success with which these ends have been attained. But self-gratulation on our present and on our past, can be but unsatisfactory, unless our future is made still more worthy of gratulation. It is our responsibilities that have given us the influential position that we hold, and if well met, they will raise that position still higher. Upon the younger men, especially, this task will rest. The pursuits of science—the courts of law—the chamber of the sick—if need be, the battle-field—call upon them for every noble quality that man or woman should possess. Availing themselves of all modern improvements, may they by every good work perpetuate the usefulness and honor of the Society, and when they recall the grand lights of wisdom and good-

ness that have for ages shone along the path of Medical Science, let the sanguine anticipations of the future be tempered with thoughtful reverence for the past.

(To be continued.)

THE HOMŒOPATHIC SALUTATORY.—Whatever may be the other merits of Dr. David Thayer's speech—reported in Tuesday's *Transcript*—he is singularly unfortunate in his personalities. He refers to a "certain teacher in a Medical College, who once made his public boast that he never had but one patient in his life, and that one died"; and identifies the gentleman referred to by a quotation from one of his printed lectures. We have taken pains to inquire into the accuracy of this statement, and find that nothing of the kind ever was or could have been said by the gentleman in question. He was physician to one of the most crowded districts of the Boston Dispensary for nearly a year; one of the physicians to the Massachusetts General Hospital for three years; and, engaged in private practice, was very often called in consultation during a period of more than ten years. There is, therefore, no meaning whatever in attributing such words to him.

It is a pity that Dr. Thayer could find nothing better to entertain the Homœopathic strangers with than such an absurd story about one of his fellow citizens.

From the Report of the City Registrar of Boston for the year 1868, we take the following statements:—"The number of births in Boston (embracing the late city of Roxbury), in the year 1868, was 7,102—3,590 males and 3,512 females, an increase of 265 over the number born the preceding year. The increase in the city of Boston was only 63, while that in the Boston Highlands was 202. The result in the newly acquired territory—where the gain is 2.14 per cent. compared with the births there in 1867—has a more agreeable aspect than is seen in Boston, where the increase is only a trifle more than one per cent.

"The population of the united cities of Boston and Roxbury cannot be far from 240,000. It follows, therefore, that the births in 1868 are in the ratio of one birth to every 33.79 persons living. Although this birth-rate is far below what it should be, and lower than it is in any European nation, with the exception of France and Belgium, it is, however, more favorable than was indicated by the rates of the last

fifteen or eighteen years; and induces the hope, at least, that the present year will not contrast unfavorably with the past.

The above statement shows what has been added to the living population; but, in estimating what the natural increase would be, but for certain causes that some might consider providential, perhaps the number of still-births should be taken into account. The number of still-births in 1868 was 482, which, added to those born alive, make 7,584—or one birth to every 31.64 persons living. But, as these cases *add* nothing to the population, nor aid in swelling the mortality, they are, therefore, very properly omitted in the consideration of both branches of the subject, and are classed by themselves.

"When it is remembered that in 1851 there was one birth in Boston to every twenty-six persons living, the present birth-rate (one to 33.79) will not fail to attract the notice of all who are interested in vital statistics, and awaken something more than curiosity. Whether prudential motives, or something worse, or both together, lie at the root of the matter, the disagreeable fact remains, and challenges serious consideration. Apart from the medical journals of the country, this subject seems to receive little notice; and even in them the discussions are of a spasmodic character, and gradually taper off into scientific disputations, which neither cure the evil, nor point to a remedy."

"The number of deaths in Boston (including the Highland district) during 1868 was 5,519—males, 2,861; females, 2,658.

"The following statement of the deaths in Boston, New York and Philadelphia, will show how the mortality in the first-named place compares with that of the last two. The reports of the deaths in New York and Philadelphia are not liable to the same objections that exist against the returns of births and marriages. As every interment requires a permit for removal, the mortality in each place is undoubtedly correctly stated:—

"Boston, 1 death to 43.48. New York, 1 to 44.19. Philadelphia, 1 to 59.74.

"New York has long borne the unenviable reputation of being little less than a plague spot. Those who have been accustomed so to regard it, will be somewhat surprised to learn, that, notwithstanding its filth, and the free-and-easy way in which public matters are conducted, its bill of mortality has a more agreeable appearance than that of Boston; while Philadelphia outstrips both in an extraordinary degree."

In the introduction to the Thirteenth Annual Report of the City Registrar (Edwin M. Snow, M.D.) of Providence, R. I., we find this statement:—

"The number of births in Providence, during the year, was 1,624; of marriages, 855; of deaths, 960. As compared with the previous year, the number of births was 8 *less*; of marriages, 43 *more*; of deaths, 76 *less*.

"Estimating the population of Providence, for the middle of the year 1867, at 57,000, which is a low estimate, the proportions to population, for the same year, were one birth in 35.1; one person married in 33.3; and one death in 59.4.\*

"When we consider that the returns of births, marriages and deaths in Providence are almost absolutely complete, the above proportions are more favorable to vital prosperity than those of any other American city of equal, or of greater size. They are, in fact, more favorable than those of our own city, in any previous year in the history of registration."

From the Third Annual Report of the Board of Trustees of the General Hospital for the Insane, of the State of Connecticut, we take the following:—

"There have been already received into the hospital, of all classes and both sexes, two hundred and sixty-eight (268) patients, of whom two hundred and nine (209) remain. Of these, one hundred and seven (107) are males, and one hundred and two (102) are females. \* \* \* Since the last annual meeting of the Board of Trustees, April 15th, 1869, the number in the hospital is 226, and there are on file and waiting for admission, sixteen applications. \* \* \* In all hospitals for the insane it is the practice to group patients of certain morbid propensities. It is the result of experience that they exert a salutary check on each other. Since the time that the northern wing was opened on the first of March, the female patients have arrived in large numbers daily, and it was impracticable to have immediate knowledge of each particular case."

We desire to call attention to a notice in our advertising columns, that, in future, diseases of the skin presenting themselves among the out-patients of the Massachusetts General Hospital, will be treated, specially, by Dr. James C. White.

\* Vide "Philadelphia" in our extracts from Boston City Registrar's Report.—Ed.

## Medical Miscellany.

EDWIN M. SNOW, M.D., Superintendent of Health in the city of Providence, R. I., says, in his Report on Smallpox:—"During the fourteen years, nearly, July, 1855, to April, 1869, ten thousand four hundred and sixty-four (10,464) persons have been vaccinated in my office. Very many more, of course, have been vaccinated, in the same time, by other physicians in the city.

"During the same fourteen years, I have myself given certificates of vaccination to sixteen thousand three hundred and thirty-two (16,332) children to enter the public schools. Probably nine tenths of these certificates were given by me, solely from the evidence furnished by the vaccination scar, and because I had full faith in the protection furnished by vaccination against the smallpox. Now note the result!

"During these same fourteen years I have known of nearly every case of smallpox in Providence, and have visited the greater portion of them myself, and I have never, during this time, seen or heard of a single case of smallpox in any scholar in the public schools, who received a vaccination certificate. These facts seem certainly to prove that vaccination has not lost its protective power.

"The reasons why smallpox has been so prevalent in California, and in some of our midland cities, during the past year, are perfectly well understood. They are not because vaccination has lost any protective power: but because vaccination has been neglected, or imperfectly applied. For the same reasons, smallpox is quite prevalent in New York city at the present time, and for the same reasons, we frequently have the disease, though to a much less extent, in this city."

PENNSYLVANIA STATE MEDICAL SOCIETY.—*Erie, June 9, 1869.* The annual meeting of the Pennsylvania State Medical Society will be held in the Court House, commencing June 9th, at 4 o'clock, P.M. Entertainments and receptions:—Wednesday evening, reception by Capt. Jonett, U.S.N., on board U.S.S. Michigan, at 8 o'clock. Thursday evening, banquet at the Reed House, at 8 o'clock. Friday, 11 o'clock, A.M., excursion on Lake Erie, in steam and pleasure yachts, and sail boats, and collation at Crystal Point at 4 o'clock, P.M. J. L. Stewart, M.D., Chairman Com. Arrangements, Erie County Society. C. Brandes, M.D., Chairman Reception Committee, Erie County Society. George C. Bennett, M.D., Chairman Com. Arrangements, State Society.

The above is a copy of a programme which has been sent us. What is more—the Committee of Arrangements had the kindness to send us an invitation to the festivities. For this courtesy we present our profound acknowledgments. Nothing but inability to leave home prevents our acceptance.

MASSACHUSETTS MEDICAL SOCIETY'S PRIZE FOR VENTILATING SICK-ROOMS. *Mr. Editor,*—The *N. Y. Medical Gazette* omitted one essential to the final success of his way of escape from the

closeness of the sick-room—viz., to let the patient have "the gates ajar," or "the gates wide open!"

The Editor of the *N. Y. Medical Gazette* may send the prize-money (when he gets it) to this office, for  
"Nuss."

PIN-WORMS AND THEIR HOMOEOPATHIC TREATMENT. *Mr. Editor,*—Dr. Buckingham wishes to suggest to the Editor of the *New England Medical Gazette*, that, if he (the Editor) will re-publish the article with the above title, which so offends the mock delicacy of that gentleman and his correspondent Vindex, it will be an accommodation to Dr. B., inasmuch as it will stop the numerous calls upon Dr. B. for the article. He regrets exceedingly that the worms have so troubled the Editor of the *Gazette* that he continues to scratch for two months after the application.

THE CASE OF SAW-WOUND OF THE SKULL.—We have received the May number of the *Pacific Medical and Surgical Journal*, containing an account of the case of recovery from a saw-wound of the skull, which we referred to a short time ago. We shall copy as soon as we can find room for it.

PIG'S milk is extremely rich, containing, as it does, nearly 50 per cent. more nutritive matter than is found in that of the cow. It is not unlikely that in certain forms of disease, where a milk diet is prescribed, the use of so concentrated a liquid food might prove serviceable.—*Dublin Med. Press and Circular.*

## MEDICAL DIARY OF THE WEEK.

MONDAY, 9, A.M., Massachusetts General Hospital, Med. Clinic. 9, A.M., City Hospital, Ophthalmic Clinic.

TUESDAY, 9, A.M., City Hospital, Medical Clinic, 10, A.M., Surgical Lecture. 9 to 11, A.M., Boston Dispensary. 9-11, A.M., Massachusetts Eye and Ear Infirmary.

WEDNESDAY, 10, A.M., Massachusetts General Hospital, Surgical Visit. 11 A.M., OPERATIONS.

THURSDAY, 9, A.M., Massachusetts General Hospital, Medical Clinic. 10, A.M., Surgical Lecture.

FRIDAY, 9, A.M., City Hospital, Ophthalmic Clinic; 10, A.M., Surgical Visit; 11, A.M., OPERATIONS. 9 to 11, A.M., Boston Dispensary.

SATURDAY, 10, A.M., Massachusetts General Hospital Surgical Visit; 11, A.M., OPERATIONS.

TO CORRESPONDENTS.—The following communications have been received:—Review of Surgical Case—Review of Holmes's Treatise on Diseases of Infancy, &c.—Congenital Cataract simulating Myopia—Insensibility to Pain from Mental Causes.

ERRATUM.—In our last issue, page 327, 2d column, line 25 from top, for "acid wine" read *acid urine*.

DEATHS IN BOSTON for the week ending Saturday noon, June 5, 85. Males, 36—Females, 49.—Abscess, 1—accident, 3—apoplexy, 1—inflammation of the bowels, 2—disease of the brain, 3—inflammation of the brain, 1—bronchitis, 4—cancer, 1—consumption, 15—debility, 2—diphtheria, 1—dropsy of the brain, 2—drowned, 1—erysipelas, 2—scarlet fever, 5—typhoid fever, 1—hemorrhage, 1—disease of the heart, 2—insanity, 1—disease of the kidneys, 2—inflammation of the lungs, 5—marasmus, 1—old age, 6—paralysis, 3—peritonitis, 1—pleurisy, 2—premature birth, 1—puerperal disease, 3—pyæmia, 1—tumor, 1—unknown, 9—whooping cough, 1.

Under 5 years of age, 19—between 5 and 20 years, 12—between 20 and 40 years, 20—between 40 and 60 years, 19—above 60 years, 15. Born in the United States, 55—Ireland, 20—other places, 10.

### MANIA TRANSITORIA.

By EDWARD JARVIS, M.D., of Dorchester.

(Concluded from page 337.)

#### EXCESS OF DESTRUCTIVENESS IN THE INSANE.

AN ordinary sane criminal, having a definite purpose, accomplishes that, and is then satisfied. If he intends to kill for revenge, for passion, or for robbery, or to prevent detection, he simply extinguishes life, and then leaves his victim. His destructive force and instruments are only used as means for an ulterior purpose, and when that is effected they cease to act, and the propensity is satisfied.

The insane homicide often uses his destructiveness as an end. He has no other purpose than to destroy. He is not satisfied with merely killing. He goes beyond. Dr. Ray says, "The criminal never sheds more blood than is necessary for the attainment of his object. The homicidal monomaniac often sacrifices all within reach of his murderous propensity."\*

A sane murderer would be satisfied with cutting the throat of his victim, or with one or two stabs in the region of the heart, or one or two blows on the head with a heavy instrument.

Tuke relates the case of a woman who cut off the head of her child with a razor, and of a man who cut off the head of his companion with the same kind of instrument.†

A few years ago, an insane man called at a house in Roxbury, on some errand. He was left alone in the parlor for a few minutes with a little child; when the mother returned, she found that the maniac had severed the child's head from the body.

Henrietta Conrier not only severed the head of the child left in her charge, but threw it out of the window into the public street.‡ Castelnau gives account of a wo-

man who cut off the head of a child with a pocket-knife, and moreover stabbed it in the head, back, abdomen, and legs. He adds, that the great number of wounds in this case was held by the distinguished psychological physicians (*medicin legists*) as a characteristic symptom of insanity.\*

Esquirol states the case of a woman who destroyed her child, by inflicting twenty-one stabs with scissors, and then threw the body into the vault of a privy.†

Dr. Woodward gives the case of a homicide by a maniac, wherein the body was found "horribly mangled; one side of the head beat in, and both arms and legs broken."‡ Dr. Bell related a case that had come under his charge. A young man struck his father repeated blows on the head with a pitchfork, and killed him.

The teamster before mentioned, 1st, abused a woman; 2d, struck another woman several blows with the hatchet; 3d, split open the head of a boy; 4th, buried the hatchet in the skull of a man, and spilled his brain on the ground, and then struck him many more blows; 5th, attacked two Jews; 6th, attacked a peasant whom he met successively in his walk on the road.

#### HEREDITARY PREDISPOSITION TO INSANITY.

The question of hereditary descent of diseases, or rather of the tendency to or susceptibility of disease from parents to children, through successive generations, is too well settled to require any further proof or argument. It is only desirable to refer to it in this connection, by way of explanation of the class of transient mental disturbances now and here under consideration.

A considerable proportion of those who have suddenly appeared to be insane, were of unsound cerebral constitution by inheritance, their parents or ancestors having been insane. Tuke, referring to this class of transient cases, says, "An inquiry into the patient's history, will generally detect a change in character; this, however, obvi-

\* *Medical Jurisprudence of Insanity*, p. 231.

ously cannot be looked for in cases where mental disorder can be traced back into infancy, or where the intellectual and moral defects are congenital."\* Again he adds, "In some persons there is rather a congenital proclivity to disease than the actual disease itself, and in these, a circumstance which, in persons without that proclivity, would produce no result, will call into action abnormal, that is to say, truly diseased, mental manifestations, although they may be only functional and subside when the exciting cause is removed."†

Devergie says, "If we examine the ancestral history of the families on the paternal or the maternal side, of these transitory maniacs, it is not rare, that one or even many members of the family have been insane for longer or shorter periods." He quotes the case of one of these patients who had committed homicide in a transitory paroxysm, "in whose family one maternal great uncle died insane; one paternal aunt killed herself, and another relative on the mother's side was known to have been troubled with eccentricities (*bizarres idées*) all her life."‡

Castelneau, describing one who, in a momentary paroxysm of mania, had killed another, said, "that her mother suffered from grave disease of the cerebro-spinal system, and had hemiplegia previous to this daughter's birth. Her grandfather was insane, and her brothers were strongly impressed with the character of her ancestors."§ Of another he says the grandmother and great-grandmother were insane, and the father considered by the neighbors as not sane.||

The young man in France, who in a sudden paroxysm shot his mother-in-law, inherited his insane proclivity through both of his parents.¶

Tuke, in the part which he contributed to the admirable conjoined work of Bucknill and Tuke on *Insanity*, quotes\*\* many cases of impulsive and homicidal mania from Henke, Esquirol, Marc, Metzer, Georget, Ray, Otto, *Annales Medico-Psychologiques*, *Gazette des Tribunaux*, *Medico-Chirurgical Review*, and other journals. Most of these are represented as sudden and transitory. He admits these, with all their elements as they are originally described, outbreaks of short duration, without preceding or succeeding manifest insanity. He supposes that, although the single paroxysm was the

only apparent mental disturbance, the cerebral constitution was not previously completely sound; that it was either originally imperfect by inherited predisposition to insanity from insane parents and ancestors, or that it had become impaired by indulgences, eccentricities, &c.; and that in either case the vitiation had not been sufficiently great or manifest to be recognized by the patients themselves or perceived by others, yet were sufficient to prepare the ground for the development of insanity, whenever a suitable exciting cause might present itself.\*

If we inquire into the mental condition of the paternal and maternal ancestors of those thus accused of crime in sudden paroxysms of mania, "it is not rare to find one or more suicides, or who have suffered from insanity for a longer or shorter period."†

#### EFFECT OF EXTERNAL DISTURBING CAUSES.

The mental as well as the physical functions are susceptible of sudden disturbances and morbid changes. Generally they come from within; sometimes they come from without. Most of the sudden outbreaks of mania are the evolution or culmination of unseen and unrecognized morbid processes; some are the result of internal causes, which human philosophy has not yet been able to explain; and some are produced by outward influences that suddenly act upon the cerebral organism, and at once disturb the functions of the brain. One is thrown out of a carriage; no physical injury is seen, yet the brain is disturbed; the shock overcomes its balance of functional action and the mind is at once deranged. A horse runs away with a chaise, and puts the passengers in great excitement and alarm, and perhaps in real danger. Nevertheless, the

\* Bucknill, in his *Essay on Criminal Lunacy*, p. 38, speaks of "those in whom the impulse is sudden, instantaneous, unreflected on, stronger than the will; the murder is commonly committed without interest or motive, and often upon the most loved objects of the affections." And adds, "The existence of this class admits of grave doubt." Bucknill does not doubt the facts, as they are presented and described, of sudden outbreak and short continuance; but he says, "It is probable that the cases of insanity which have been placed under this head, were less recent and sudden than they were supposed to be. The earlier stages of diseased feeling had been unobserved by others and unacknowledged by the patient." This essay was written in 1854. It does not mention hereditary taint among the cerebral imperfections predisposing to these sudden maniacal attacks. But in the work which he, in conjunction with Tuke, published four years later, the hereditary predisposition is mentioned (page 186), in this connection. The later work further adds, beside the majority of cases in which the precursory "stages of diseased" and "congenital proclivity," there are left "a considerable number of cases in which there is a blind, motiveless, unreasoning impulse to kill." Bucknill and Tuke on *Insanity*, p. 201.

animal is arrested; the passengers are bodily safe, but the fright has overpowered the senses of one; she is confused, bewildered, insane.

Many writers on insanity and many hospital superintendents include *fright* among the causes of mental disorder. Esquirol speaks of it as a common cause, and says, that it produced forty-six out of twelve hundred and eighteen admitted at the Charenton and Salpêtrière hospitals under his charge.\* Dr. Choate reports seventeen cases from fright among three thousand three hundred and ninety patients received at his hospital in Taunton in fifteen years.† The Worcester Hospital reports forty-five in thirty-six years.‡ The Hartford reports twenty-one among four thousand eight hundred and ninety-eight patients.§ The State Hospital of Utica, N. Y., reports forty-seven cases of fright in nineteen years of its operations.|| Most hospitals present a similar history. The same is found in English and Scotch hospital reports.

Females are somewhat more susceptible of mental disturbance from this sudden disturbing cause than males, yet the records of lunatic hospitals do not present a very great difference between the sexes, in this respect. Of the forty-five cases admitted at Worcester from this cause, twenty-one were men and twenty-four were women. Dr. Choate reports six men and eleven women received at Taunton from this cause. The nineteen American hospitals, which report the causes separately for each sex, received one hundred and thirty-one males and one hundred and eighty-three females who were made insane by fright, and twenty-six British and Irish asylums report one hundred and fifty-five male and three hundred and fifty-three female patients whose insanity was due to this sudden disturbing influence. Some hospitals report cases of insanity produced by other outward influences that speedily overpower the brain; shock, sunstroke, firing cannon, excitement of religious and political meetings.

Fright is an absorbing emotion quickly following some appalling event or impression on the mind and feelings. Shock comes as suddenly and is as rapid in its effects. The consequences of the firing of cannon and sunstroke belong to the same category. These outward influences fall at once on the brain and at once disturb its functional operations, and the sufferer is immediately unbalanced and disordered in mind.

Esquirol mentions a woman who was

made a maniac in a moment by a thunder-clap.\* Take gives fright as one of the moral causes of insanity.† Bucknill, in his Essay on Criminal Lunacy, refers to mental shock of grief or disappointment as cause of mental disease.‡

Castelnau quotes Bellard, who speaks of those that instantaneously lose their reason from the effect of a great grief, great surprise or other cause of this kind.§ Pinel says, that some persons of extreme sensibility may, by some keen and sudden affection, be so intensely moved as to suspend or even destroy all moral power. An excessive joy or fright produces this inexplicable phenomenon, and hence, says Castelnau, even dementia may be suddenly produced.|| Castelnau gives the instance of an inventor of an improved cannon, which met the approbation of the French Government. He was struck senseless by reading the official letter of commendation, and was sent at once to the Bicêtre in a state of dementia.¶

Bucknill says, "The delusions of the insane come on after some physical or moral shock, and often present strange contrasts to the previous habits of thought or have no relation thereto."\*\*\*

Those who have the care of the insane always hold in mind the great sensitiveness of their patients and their susceptibility of sudden excitement and outbreak. With this fear, they keep their patients from disturbing causes arising from persons with them, or circumstances that surround them. They endeavor to keep them under the most calming and soothing influence. They allow none but the most discreet, gentle, and self-disciplined to have the care of or approach them. All the officers, attendants and companions are selected with this view.

A superintendent of an asylum once told me that, a few weeks previously, a ward of ordinarily very quiet, peaceable patients, was suddenly thrown into excitement, with paroxysms of fury and contention, by the introduction of a new attendant, who was indiscreet, hasty, and irritating; but the storm subsided by the second change, and the substitution of a more skilful attendant.

In August, 1843, I was sitting at a window of the Worcester Hospital with Dr. Woodward. He called my attention to a number of men working in the field near by, to their quietness and order. He said "They were patients under one attendant;

two of them were homicides. Each of these had killed a friend, in a sudden outbreak of mania, when they were supposed to be sane. And now they were working as calmly and apparently as safely as any sane farmers." I asked him if there was no danger now. He said, "No, not as we manage them. We select for their attendants, men who are amiable, self-chastened and respectful, who understand the liabilities of these patients, and know how to humor their wayward caprices, and are willing to do so. But if we should do otherwise, and put these susceptible patients under the management of indiscreet or passionate men, they might be suddenly provoked, and in a moment strike down their guardian, or any one near them, with their hoe or spade."

"Some time last year a patient was at work in the field, hoeing corn. His attendant directed him to vary his labor in some way. In a moment he raised his hoe and struck him over the head."\*

Sunstroke is a common cause of sudden cerebral and mental disturbance. Poderé says, "Temporary delirium is caused by the action of the sun on the bare head, and by excessive cold."† Hospital reports give abundant evidence of a speedy change from sanity to lunacy produced by this course. Nineteen cases from sunstroke were received at Worcester in thirty-six years, and twenty-four at Taunton in fifteen years.‡

#### THE FUNCTIONS OF OTHER ORGANS SOMETIMES SUDDENLY DISTURBED.

The functional operations of other organs, as well as those of the brain, are sometimes suddenly disturbed or even suspended, and disease may supervene in them, rapidly, almost instantaneously. Persons subject to rheumatism, and especially those who inherit it from parents, are especially liable to the sudden appearance of their malady. In two persons, now and for many years under my observation, it sometimes comes with the sensation of a blow from a club or a lancet. This may be from exposure to cold, or from exertion, but very commonly from no known cause. The attack usually leaves a painful soreness, and difficulty of motion for a few hours or days, and gradually fades away. Sometimes the pain and weakness last but a moment, and sometimes, after hours or days continuance, it suddenly disappears.

The Report of the health of Towns Com-

mission states, that when, on one occasion, the trap of a very foul sewer in London was suddenly opened, there issued from it a stream of gas of intense oppressiveness, and two men, standing over it, inhaled it, and were at once struck down with typhus fever. When epidemic cholera pervades the community, some of its attacks are as sudden. Digestion is sometimes suddenly arrested by the presence of food which is unsuitable for the stomach. It is sometimes arrested by sudden mental shock or alarm.

Disturbances of the physical system sometimes suddenly disappear. A patient had for six weeks neuralgia of intense severity; after trials of manifold remedies without apparent effect, at length the pain ceased at once, and left the sufferer entirely free, yet weak.

After reading the charge of the learned Chief Justice, as delivered, and the testimony of the experts with the constructors, the reader will judge of the temper and fairness of the subjoined article, which is taken from the issue of the *Boston Transcript* of Dec. 12, 1868. It is difficult to decide whether it is more an attack upon the impartial Judge, or the learned and conscientious expert.

*Medical Experts in Courts of Justice* hold a relation to the courts and the jury, to the accused and to the community, that is of the greatest importance and responsibility. Following their expressed opinions, courts and juries may be led into errors, the accused may be wrongfully condemned or acquitted, as the case may be, or the community may be deprived of an innocent member, on the one hand, or have thrown upon it the most guilty criminal on the other. Besides, if the conviction be entertained that their tendency is toward the criminal, it weakens the force of the law, inasmuch as it inspires a hope, if it does not give actual assurance, that its severity will be mitigated by the aid of some over-sympathetic humanitarian, or friendly, and it may be well paid, medical man.

That medical men, rather than medical sciences, have suffered in the opinion of the courts from faultiness in the above direction, is evident from the bold, decisive and pointed words of Chief Justice Chapman in his charge to the jury in the case of Andrews at Plymouth, recently, when he said: "The opinions of experts are not so valued as in other days. Many experts can be hired for the occasion. You must judge yourselves of the evidence offered you."

† *Traité du Délire*, i. 425.

‡ Annual Reports, 1868.

Surely no plainer words could have fallen from the court, and a severer thrust than it has not been made at the medical profession in many a day; and if their pride can be touched, and their sense of honor stimulated, it would seem as though the exciting cause for such emotions and efforts had now been presented.

#### THE PHYSIOLOGICAL AND THERAPEUTIC RELATIONSHIPS OF ERGOT OF RYE.

By FRANK W. DRAPER, M.D.

(Continued from page 341.)

**THERAPEUTICS.**—So readily are the therapeutic relationships of this important agent inferred from the study of its physiological action, that the indications for its use need hardly be discussed at length. Indeed, so numerous are the accredited occasions for its practical application, that the recorded different instances in which it has been found efficacious would by themselves fill a volume, exhibiting proofs of the most extraordinary powers, and placing it in the very front rank of therapeutic agents. For example, it is claimed by one author to have, for its destiny, to supersede entirely the use of forceps in obstetric practice; while another advocate of its omnipotence says enthusiastically that were it introduced to general practice, the death of a woman in childbirth would never be heard of. (Mitchel on Ergot, p. 78.) Boujean places it at the head of hæmostatic agents, and urges its use in various surgical operations where ligatures are now employed; while for its use in dysentery and in whooping cough, in albuminuria and in asthma, in neuralgia, in gonorrhœa, and in a multitude of other diseases, its advocates are sufficiently numerous to almost warrant its title of universal panacea, and, with a surfeit of virtues, to enable it to partake of the unenviable pretensions of advertised nostrums. In thus passing through the trying ordeal of therapeutic fashion, ergot, in common with all valuable remedies, has been in danger of being sacrificed through the ardor of its friends; but its efficacy is now too well recognized to permit its exposure to any such fear for the future. But from all this apparent diversity and incongruity in its practical applications, it is still possible to deduce a single rule for its general employment, the direct corollary of its physiological action—*whenever it is desirable to stimulate and contract the unstripped muscular fibre, then the use of ergot is indicated.* To the test of this rule its powers as an astrin-

gent, a sedative, a hæmostatic, a parturifacient, in all their seemingly anomalous phases, may be at once referred. The conditions of its action must, of course, be favorable, else, on the one hand, no effect will follow, and we shall say with Madame LaChapelle, "its innocence is its greatest virtue"; or, on the other, its action will be unexpectedly disastrous, and we shall lean to the side which declares that "its introduction into practice has been productive of more harm than good." But between these two extremes is a safe mean wherein its judicious use is the source of indescribable blessing.

It should be remembered, however, that for reasons already referred to, we must not expect a uniform effect on all the parts supposed to be susceptible to the influence of ergot. Nor must it be forgotten that as a necessary result of its general constitutional effect, we must be prepared for symptoms quite unlike those for which the dose was administered, and, it may be, for the time, harmful. Thus it is possible that, in uterine hæmorrhage, our ergot will not only control the flooding, but, at the same time, produce a distressing nausea and alarming depression entirely unlooked for; or, if given to a pregnant female for the relief of myelitis, it may send into the world, "scarce half made up," the ill-fated occupant of the gravid uterus. But if with the beneficent results of the administration of spurred rye we must also expect the undesirable, proper discrimination may still anticipate and avert disasters.

Its earliest as well as its most important use ranks it as the first of parturifacient agents. For nearly three centuries it has been thus employed, and upon its uses, its virtues and its abuses in this direction, have depended the sharp differences of opinion which have sometimes developed to acrimony. The mode of its action and the attendant phenomena have been considered. If in any hands it fails to give good results, the fault is either in the quality of the drug used, or in the unfavorable condition of the patient, either for the time being or through permanent idiosyncrasy. The conditions modifying its action in labor are both mechanical and vital. Thus, an undilatable os tince, a narrowed pelvis, a hydrocephalic head, would offer obvious obstacles to a normal labor which ergot could hardly be expected to overcome. And again, the condition of the patient may have become so depressed, from exhaustion or other causes, that ergot would fail to create its proper effects. So clearly has this been

shown by Dr. Murphy that it may be well to transcribe his own words. "In order," he says, "to excite the action of this or of any other medicine, the nervous system should be capable of conveying the necessary impressions; but when this is not the case, *secale cornutum* cannot stimulate the uterus; nevertheless, if it regain its irritability, or if ergot be given before the uterus has lost its tone, in either case its efficacy is undoubted, and it may be usefully employed. Assuming this explanation as true, ergot of rye may be contrasted with opium. When the nerves of the uterus have lost their natural irritability, and the uterus is in a state of atony, opium is the most efficient excitant to its action, because it then acts on these nerves as a most powerful stimulant; but when that irritability is restored, or if it be only slightly impaired, it acts as a sedative, and may paralyze the uterus. Ergot, on the contrary, is quite inefficient in nervous exhaustion of the uterus, because so far from acting to stimulate in such cases, its effect tends towards sedation, while its specific effect is produced the moment that exhaustion is removed." (Murphy's *Obstetrics*, p. 273.)

The dangers which are said to attend the use of *secale cornutum* in labor are serious and often truly formidable. Rupture of the uterus, puerperal convulsions, irregular uterine contraction, separation of the placenta and violent flooding, prolapse and procidentia, retained placenta, coma and even death, are attributed to its use. Some of these, depending on inevitable and unforeseen conditions, would perhaps follow in spite of the use of any therapeutic agent, or possibly, the more readily, in some cases, were such a remedy avoided; while many if not most of the fatal cases may be fairly attributable to the use of a powerful agent in inexperienced or ignorant hands, regardless of reasonable rules for guidance in such cases.

The indications for the use of ergot in parturition may be considered in two classes of cases—the *ante-puerperal*; including instances in which it may be used before the expulsion of the fetus, to aid in that process; and the *post-puerperal*, comprising conditions favorable to its action after that stage. In the former may be mentioned—  
I. Tedious labor. II. Premature labor. III. Normal labor, when it is desirable to hasten the process when the life of the child or of the mother is endangered. The second class contains cases of—  
I. Puerperal hæmorrhage. II. Retained placenta, depending on uterine inertia. III. Retention within the uterine cavity of clots of blood

and other puerperal matters, such as fragments of placenta or of the membranes.

In tedious labor, which, according to Churchill, is understood to mean parturition in which no manual or instrumental interference is used, but which is prolonged more than twenty-four hours from causes which occasion delay in the first stage, ergot is of use to supply renewed force to a uterus exhausted or too debilitated to overcome the continued resistance. The conditions favorable for its employment are, on the authority of the same writer, "when the pains are feeble and inefficient without especial cause; if the os uteri be soft and dilatable; if there be no obstacle to the natural delivery; if the head or breech present and be sufficiently advanced; and if there be no threatening head symptoms nor excessive general irritability." (Churchill's *Midwifery*, p. 264.) The conservative and rational policy of Dr. Coudie would modify these rules, so that ergot should not be used until the os uteri is not only dilatable but is fully dilated, and the other soft parts are in a favorable state of relaxation. This would appear to be the more prudent course, to the end that all necessary safeguards might be established. Desgranges, an enthusiastic advocate of ergot in the last century, recommended its use in hastening tardy dilatation of the neck of the uterus, and cites numerous confirmatory cases. But such employment is manifestly attended with no slight risk to both mother and child, for the incessant, unremitting uterine contractions induced by ergot, especially if no outlet be provided for the escape of the contents of the womb, must necessarily have a deleterious effect, in a mechanical point of view, on the fetus, while the exhaustion to the uterus itself and to the whole maternal system is increased by the ineffectual influence of an extraneous agent, to the degree that convulsions sometimes result.

The use of spurred rye in premature labor, to hasten or produce it, when such a proceeding is unfortunately necessary, depends on a question scarcely solved even to-day—the power of that remedy to initiate uterine contractions. Rationally and consistently, according to the proposed theory of its physiological action, such an effect is to be looked for. If the theory of its action is true, it should apply to the uterus when unimpregnated, or in the early stages of fetal development, no less than at full time, when normal contractions have already commenced, the difference being only one of degree. Authorities are not

wanting in support of this view. Thus, Churchill, in discussing the method to be used in the induction of premature labor, says of ergot of rye, that "it is now generally believed to have the power of originating uterine contractions, and when it succeeds, it is a very effectual and safe mode of inducing premature labor, because we can preserve to the child the safeguard of the liquor amnii, which is of the greatest importance." (*Midwifery*, page 308.) Ramsbotham has published cases in which ergot was thus found efficacious, and advocates its use. (*Medical Times and Gazette*, 1854-1856.) So firm was the professional opinion in France that this power to produce abortion resided specially in ergot, that the Royal Academy urged its exclusion from practice. It has been repeatedly noticed that pregnant women exposed to the chronic effects of ergot, show a very decided tendency to abortion at any stage of pregnancy. It is to be remembered that the peculiar action is marked in proportion to the extent of the muscular tissue exposed; and if, in the early stages of pregnancy, we fail to experience the ready and decided effects of ergot which mark its influence in normal labor, much of the difference may be explained in this way. If, moreover, it is not to be wholly relied on as a means for the induction of premature labor, we have in it, at all events, a powerful agent for the supplementing of other means; if, after mechanical appliances have been resorted to, to separate the uterine membranes or to dilate the os tincas forcibly, it is required to expedite the expulsion of the foetus, ergot seems a ready agent to complete the process.

There are, thirdly, conditions in normal labor, rare and exceptional, when it is desirable to finish the act as soon as practicable. Thus if, at any stage, puerperal convulsions should develop, or if unexpected hæmorrhage should occur, or if some condition of the child should indicate it, we should look for other means than the natural labor pains to hasten the act of parturition. Such an aid we have either in the uterine forceps or in the agent we are studying.

In this discussion of the use of *secale cornutum* in ante-partum cases, one very essential element requires consideration—the effect on the foetus in utero. Authorities are too numerous to be controverted, that spurred rye is dangerous to the life of the child in labor. The symptoms in living children who have been born with the assistance of this remedy are too well marked, and the

appearance in those stillborn are too characteristic to induce any belief other than that they are to be referred, primarily or secondarily, to its unfavorable influence. This deleterious effect on the child, whether it be fatal or whether it produce a less degree of harm, may be explained in three ways:—first, the mechanical action of the continued and uninterrupted ergotic contractions of the uterine on the body of the foetus, must obviously be more or less harmful, compressing the brain, cramping the limbs, and compromising the circulation; secondly, the same incessant tonic contraction, acting at once on the muscular tissue and on the vessels of the uterus, tends directly to impede both the uterine and the foetal circulation, thus allowing no truce to repair exhaustion, and to permit fresh blood to enter the partially emptied vessels; while at a distance from the uterus, the secondary sedative effect on the heart also modifies the normal circulation; thirdly, so long as the foetus is attached by its umbilical cord to the uterus, deriving its nourishment from that source, its susceptible organism must be more or less exposed to the toxic influence of ergot, through the maternal circulation, in common with every other part. Observing the peculiar phenomena in children born alive or still, after the use of spurred rye in labor, and identifying them with the symptoms of acute ergotism, Dr. Beatty has concluded that most of the fatal cases in children in ergotic labor are induced by an exposure of more than two hours to the poisonous effects of ergot through the blood of the mother. In many cases, also, in which the children survived, he has noticed modified ergotism and secondary permanent effects, manifested chiefly through the nervous system, and attributed by him to the same cause. His numerous observations in this direction have therefore led him to establish the rule that ergot should not be given in any case in which the labor will not terminate within two hours, since the probabilities are vastly in favor of a fatal toxicological effect on the foetus, if it be exposed beyond that period.

In the second general class of cases in which *secale cornutum* is of use in parturition, those, namely, after the birth of the child, the first order, including cases of puerperal hæmorrhage, is by far the most important, and illustrates most fully the beneficial effects of this remedy. The foetal contents of the uterus having been expelled, that organ itself exhausted by its prolonged labor, and incapable, for the present, of spontaneous contraction, the placenta either

wholly detached and lying inertly in the cavity of the womb or only partially separated, and as a consequence, in either case, a steady and most alarming escape of blood, putting the life of the patient in momentary jeopardy; all these conditions constitute a most serious combination, and any agent endowed with power to relieve it is of incalculable value. The indication is to stimulate the relaxed and wearied uterus to renewed action; whatever will do this will close the exposed mouths of the uterine vessels, complete the detachment of the placenta, and expel it, and thus at once effectually control a condition acknowledged to be the most alarming in the experience of the accoucheur. In conformity with the proposed theory of its physiological action, ergot acts in three ways to control the hæmorrhage:—first, the muscular fibres of the uterus are revived to renewed action by the direct stimulant power of the drug, thus necessarily closing the uterine vessels; secondly, the calibre of the vessels themselves is lessened and the flow of blood diminished; and thirdly, the flow of blood is also modified by the general sedative effect on the heart and circulation. All these results being produced in unison, an early and favorable effect is produced. And fortunately, in view of the formidable nature of the accident, the conditions which are to be remembered as favorable to its action are few and obvious. There is now no fœtus to fall a possible victim to ergotism; there is no danger of rupture of the uterus or of any of the concomitant accidents of labor when ergot is used as an adjuvant. The indication is to contract the uterus, and the principal condition for the action of ergot in such an emergency is that the nervous irritability of the patient shall not have become exhausted to such an extent that the medicine would fail to exercise its influence. To this end many excellent authorities are in the habit of administering *secale cornutum* as a prophylactic to flooding, and to women known to be predisposed to post partum hæmorrhage, or in cases even of doubt, they give the requisite dose at the close of the second stage of labor. This practice is generally attended with most satisfactory consequences. The third stage proceeds at once, and the whole labor is terminated without complication.

The indications for the use of ergot in cases included in the second and third classes of post-partum conditions, those in which the placenta, or any detached portion of it, is retained through inertia of the uterus, or in which coagula or fragments of

the membranes remain as foreign bodies, to provoke renewed hæmorrhage by their presence, are so obvious and follow so closely on the conclusions already expressed, that they need no farther elaboration. So, too, the efficacy of spurred rye in expediting the expulsion of other bodies from the cavity of the uterus, besides those attendant on the puerperal state, is manifest. Great reliance is placed upon it in the management of polypi of the uterus, hydatids and other abnormal growths.

That hæmorrhage under other conditions and in other parts of the body than those peculiar to parturition should be, in greater or less degree, amenable to the hæmostatic power of ergot, is readily inferred. The analogy is sufficiently clear and universal. Having a power to act on the inorganic muscular fibre, residing not in any chemical influence, but in its vital action as a special astringent, its utility in certain cases of hæmorrhage is obvious theoretically and is confirmed in practice. Menorrhagia, metrorrhagia, epistaxis, hæmatemesis, hæmoptysis, hæmaturia, rectal hæmorrhage and that depending on cancer, hæmorrhoids or scurvy, the hæmorrhage of dysentery, are thus all susceptible of successful control by ergot, since they are all dependent on an analogous condition or lesion of the capillaries. This result is especially marked, if with the hæmorrhagic symptoms a firm, bounding pulse indicate a sthenic condition of the circulation, since the secondary depressing influence on the general circulation must have a direct tendency to control the escape of blood. This is of general application in idiopathic or in traumatic hæmorrhage from the capillaries, and the cases of its efficacy in all the conditions mentioned are sufficiently multiplied to establish the prestige of ergot in this relation, whether it be administered internally or locally.

There are even authorities for giving to *secale cornutum* a still higher place as a hæmostatic agent. In 1843, the Royal Academy of Sciences in France reported, through its Secretary, that "ergotine is the most powerful remedy which medical science possesses to control arterial or venous hæmorrhage"; and three years later, the Royal Academy of Turin concluded that "ergot was a hæmostatic agent especially appropriate to arrest arterial hæmorrhage, even in great vessels, without occluding them." Without claiming for spurred rye that it will entirely supersede the use of the ligature in surgery, M. Bonjean urges its local, external use in many

cases in which ligation would generally be resorted to, involving inconvenient if not grave operative complications. He even goes farther, and cites cases in which, under the effects of ergot of rye as a surgical dressing, by means of tampons or otherwise, lacerated wounds of considerable extent have healed "with very little suppuration or inflammation, and sometimes even by the first intention," owing, as he believes, to the depressing influence on the adjacent parts. (On Ergotism, p. 12 et seq.)

These results, although stated with emphatic directness, and supported by well authenticated authority, and moreover confirmed by cases of remarkable cure, have hardly given to ergot, in our time, an important place among surgical therapeutic agents for the arrest of hæmorrhage, or for other indications, and appear to need still further proof.

Among the more indirect and anomalous indications for the use of spurred rye, most of them substantiated by trustworthy cases, many of them founded on empirical experience, and all of them probably dependent on the secondary effects of the drug, acting through the circulation to modify the nutrition of the diseased parts, may be mentioned the various affections of the mucous membranes, such as bronchitis, leucorrhœa, diarrhœa and gonorrhœa in their chronic stages. Gubler, in common with other writers, urges its utility in alleviation of either the passive or the inflammatory congestion of the unimpregnated uterus, in incontinence of urine on account of deficient tonicity of the sphincter of the bladder, in spermatorrhœa under similar conditions, and in calculus of the bladder to aid in the expulsion of the fragments. And at a still greater distance from the more obvious conditions subject to the proposed theory of its action, and indeed in some degree savouring of homœopathic inconsistency, may be mentioned the use of ergot in puerperal convulsions (Gendrin, Baylis's Commentaries, p. 448); in the puerperal after-pains (Beatty, op. cit.); and in intermittent fever (Pereira, Mat. Med. p. 82). Others recommend its use in whooping-cough (*Edin. Med. and Surg. Jour.*, vol. ix. p. 56) and in amenorrhœa (Giacomini, op. cit. p. 330). It is difficult to account for the action of ergot in these cases on any uniform principle, if we accept at the outset the fact of its efficacy.

In more manifest accord with the theory of action proposed may be noted the general application of *secale cornutum* in all inflammatory states (Hartshorne, Essentials

of Pract. Medicine, p. 90). Illustrative of this, we may cite the observations of Parola, who found it useful in the first stage of pneumonia and in diarrhœa and peritonitis.

Finally, it remains to allude to a class of cases in which the efficacy of ergot depends on its continued stimulant action on the muscular elements of the vessels supplying the nutrition of the spinal cord. In 1831 Barbier first employed spurred rye in paraplegia, complicated with retention of urine, and with good success. (Rev. Med. xiii. p. 332.) Subsequent similar results were attained by various observers, and on various theories. It was reserved, however, for Prof. Brown-Séquard to elucidate its action and to propound rules which should govern its employment. Having demonstrated experimentally that ergot in common with belladonna had the power of diminishing the congestion of the spinal cord, he reasonably applied those remedies to cases of paraplegia depending on myelitis or on simple congestion; the attendant hyperæmia being the requisite indication, in contradistinction to the condition in white or non-inflammatory softening. He establishes it as a rule of universal application, that ergot is to be used in paraplegia only in cases in which the symptoms of irritation indicate some inflammatory change in the cord or its membranes; and among these symptoms he enumerates altered sensations of heat and cold, continued cramps of the abdominal or thoracic muscles at the upper limit of the inflammation, giving a feeling as of a tight band around the body, referred sensations of formication, of pricking or of heat and cold, and general muscular spasms. He thus draws a marked distinction between cases in which ergot is useful by temporarily modifying the nutrition of the cord, and other conditions in which such a proceeding would result in positive harm by still farther compromising the supply of blood, already too greatly diminished (*Lancet*, Dec., 1860, p. 605). To all states, then, of the spinal cord, in which congestion is a present symptom, ergot is applicable; and in support of this, abundant clinical evidence is adduced demonstrating its efficacy in such cases.

The dose of ergot for fulfilling these therapeutic indications is either simple or continued; the former applicable to cases in which it is liable to produce marked and immediate effects without repetition of the administration, and the latter to those in which continued action is sought. The obstetrical indications illustrate the one, and the conditions in myelitis, the other. In

obstetric practice, the infusion of the crude drug, freshly powdered, is preferred, greater certainty of action being secured. The formula of Dr. Beatty directs the infusion of two scruples of ergot in four fluid ounces of boiling water, and of this one half is administered at a dose. The fluid-extract is also largely used, each minim representing one grain of the drug. For the continued action the standard dose is five grains. The ergotine of Bonjean, much used in France, is given in doses of from one to three grains.

This study of the psychological and therapeutic relationships of ergot is not intended as a complete or exhaustive review of its characteristic powers. The object has been to present, in a brief way, a *résumé* of the latest views, by the best authorities, concerning a remedial agent whose legitimate use has placed it in the first order of importance in the *materia medica*, establishing for it a position which all the evils, attending its abuse, can hardly compromise.

## Medical and Surgical Journal.

---

BOSTON: THURSDAY, JUNE 17, 1869.

---

WE have alluded, in a former number of this JOURNAL, to the experiments of Cohnheim upon the *white* corpuscles of the blood, and to the doubts thrown upon their accuracy by Balogh. We now give extracts from a translation by S. Nickles, M.D., in the *Western Journal of Medicine*, of a paper by Cohnheim on Congestion, with especial reference to the behavior of the *red* globules. These extracts we follow with an abstract from the French, which speaks for itself.

"Cohnheim publishes (*Virch. Arch.*, xli. p. 227) an investigation on venous congestion, which is closely related with his researches on inflammation and suppuration. The object of the inquiry was to ascertain why, in passive hyperæmia, a plasmatic fluid (*œdema*) transudes very copiously, while, on the contrary, lymphatic elements (*phlegmon*) find egress in but limited amount.

"Cohnheim selected for his observations the web of frogs which had been treated with curara poison, and in which, by means

of a simple and suitable contrivance for regulating the firmness of a ligature, he could absolutely control the circulation of the femoral vein. He found that soon after the ligation of the crural vein, the movement of the blood in all the vessels of the web became *pulsative* and *rhythmical*, while, at the same time, the *rapidity* of the *current gradually diminished*, so that, finally, one gets the impression of a resting mass pressed onward only at intervals, by the pulse-move. The cause of this phenomenon is, that the resistance in the veins and capillaries has become so great from the sudden closure of the crural vein, that it can be overcome only by the systole. *Edematous infiltration* of the web begins very early, while the *axial character of the current disappears* in the arteries and veins, and soon, with but *moderate dilatation*, all the vessels become *densely filled with blood corpuscles*, of which the red ones are so placed in the capillaries that not the edge but the surface is struck by the current. The accumulation of the red corpuscles increases gradually to such a degree that their outlines seem to blend with one another, and a few minutes later the capillary vessel presents a homogeneous, red, immovable cylinder, which soon changes its color from a light yellowish or greenish red to a bluish red, the color of venous blood. Without any marked alteration in the interior of the capillaries, one may now observe on their outward periphery the protrusion of *small red, rounded elevations*, which form lateral offshoots, not unlike little mulberries, and their collapse and change into ordinary red blood corpuscles. If the ligature of the femoral vein is now removed, the normal conditions are soon reestablished, the red corpuscles, one by one, becoming separated in the direction of the veins from the apparently homogeneous cylinders. Of course the red masses already exuded into the tissues are not affected by this restorative process, whereas, the intracapillary part of cells about passing through the walls, is lashed by the current of blood until it is torn off and carried away."

"That, on the contrary, the red corpuscles do indeed pass through the *unbroken wall of the vessel*; that, in other words, really a *hemorrhage per diapedesin* and not per *rhecin* presents itself, is shown by the circumstance that as soon as the circulation again becomes free and the pressure upon the capillaries remits, not a single corpuscle follows those already exuded."

PATHOGENESIS OF HÆMORRHAGE.—In connection with the preceding extracts, we give a passage we have translated from the *Gazette Hebdomadaire* of a sketch of M. Bouchard's thesis, presented at *Concours*—subject, Pathogenesis of Hæmorrhage.

No true hæmorrhage can occur without preliminary rupture of a vascular wall. The *diapedesis*, or transudation of blood, with all its constituent elements, should be altogether rejected. We should look upon effusions of colored serosity as only pseudo-hæmorrhages resulting from the exosmosis of fluid holding in solution hæmatin given out by altered globules. The recent experiments of Cohnheim, which are claimed to show that globules are capable of passing through the vessels by way of preëxisting apertures—stomata—are open to doubt on the grounds of physiology, of demonstration, and of the interpretation of the phenomena. In an extended and noteworthy discussion of the question, M. Bouchard establishes the point that those phenomena throw no light on the pathogenesis of hæmorrhage.

Now, vascular rupture being indispensable and necessary to the occurrence of hæmorrhage, what are the conditions which preside over such rupture? They are of three classes: exaggeration of the tension of the blood; diminution of the external pressure and of the support furnished to the vessel by the surrounding parts; alteration in the firmness of the vascular wall. These three causes may concur in the production of hæmorrhage; or either one may cause it independently of the others. In the latter case, there are certain anatomical and physiological conditions of the circulation which favor the vascular rupture in this or that part of the circulatory system.

THE CITY GUESTS AT MUSIC HALL, JUNE 9th.—One of the penalties of His Honor Mayor Shurtleff's political eminence is the necessity of welcoming City visitors of all sorts; though we suppose it is just possible that in some cases the medical position may be sunk quite as far as is desirable in the politician. But, he doubtless remembers that when the "root and yarb" old ladies of the "Halle" call upon the Em-

peror, the Emperor is expected to take off his hat and do the honors. Running our eye down the newspaper columns we see nothing (beyond the silly story we adverted to last week) especially worthy of note in connection with the visit to the "City of Notions" of the miscellaneous assemblage of large dosers, small dosers, and hybrids, who in these days congregate under the "homœopathic" trade-mark, unless it be that they continue to pronounce the solemn opinion that in their judgment the rest of the medical world are "allopathic."

ANNUAL MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY.—(*Second Day's Proceedings, concluded.*)

The Chairman then gave the sentiment—  
"God save the Commonwealth of Massachusetts."

Until within a late hour we had hoped that His Excellency, Gov. Claflin, would honor this occasion with his personal presence, but he is unavoidably absent.

In the early days of our colonial history the Chief Magistrate was not unfrequently the medical as well as the political adviser of the community. Whatever the gubernatorial theory and practice of those days may have been, we are fortunate in having in these recent and more stormy times one to whom the medical and surgical affairs of the State can be safely intrusted.

In the absence of the Chief Magistrate, I call on that most popular of Massachusetts generals during the war, Surgeon-general Dale.

Dr. Dale thus replied:—

His Excellency the Governor of the Commonwealth directs me, Mr. President, to express to you and the Fellows of the Massachusetts Medical Society his regrets that pressing official duties prevent his acceptance of your kind invitation.

He further directs me to say that, cordially endorsing the views of his distinguished predecessors in the Executive chair, he gratefully recognizes our venerable Society as the legitimate exponent of all matters connected with the profession, acknowledges its usefulness as the honored and faithful conservator of medical science, and entertains for it and its Fellows the highest respect. It would have given him great pleasure to have joined the Society in a recognition of the patriotism, public services, integrity of life and professional eminence of the distinguished orator of the day.

Our illustrious Governor, said Dr. Upham, for aught I know, may be detained on examination before the State Constabulary Committee. I will therefore summon our distinguished fellow-citizen and professional brother, the municipal head of the city of Boston, to tell us if he has found anything rotten in Denmark—and if so, what is the remedy he would propose.

Mayor Shurtleff spoke as follows:—

*Mr. Chairman and Fellows of the Medical Society:*—For this sentiment of respect to the city of Boston, and for the kind manner in which it has been received by this Society, I thank you most sincerely. It gives me great pleasure to be with you again to-day, and renew my most agreeable associations with the brethren of a profession of which for more than thirty-five years I have been an active member; and this, assuredly, should entitle me to feel that I am not, on this occasion, with strangers, at least with the older portion of the medical gentlemen gathered around these tables. You need not be told by me that you are assembled in a city whose people most highly appreciate the ministering cares of your daily avocation. Boston has always been preëminent in respecting the good physician; and the profession has always allowed to Boston some of its most distinguished practitioners. Here medical men have always taken an interest in all useful and benevolent projects, and here they can be found holding high positions of trust, counsel and work in all matters that are good and beneficial to the community. I will not, however, take up your time at this festal board by any panegyric of the profession; for I can add little or nothing to what you already know; but I certainly should be recreant to my own feelings of loyalty and affection were I to allow this opportunity to pass without joining with you in renewing my most unqualified allegiance to this most honorable and illustrious Society of most enlightened and philanthropic gentlemen. And let me assure you, brethren, that it is a great comfort as well as pleasure, in these days, when our good old quiet city is liable to be disturbed by all the various discordant elements which originate and cultivate useless and evil-disposed schisms and associations, to greet with the warmest welcome the genial and benevolent faces of the Fellows of the Massachusetts Medical Society on their annual advent to this city.

The next sentiment proposed was—

*The Clergy*—occupying the middle and neutral ground between the physician and

his patient, they are the trusted and friendly counsellors of both—welcome in our joyous hours of recreation and festivity;—thrice welcome at the bedside of diseased and dying humanity.

The Rev. Dr. Lothrop, in responding, spoke as follows:—

Mr. Chairman,—I thank you for the sentiment you have just offered in recognition of my profession. I thank you for the honor of being a guest here to-day, for the satisfaction of meeting so many of the noble profession to which you belong, and of joining in the anniversary festivities of a Society whose record is so fair, without a spot or blemish, as the Massachusetts Medical Society—a Society that numbers on its list of past and present members, the living and the dead, so many names of distinguished and useful men, and that has done so much to elevate and keep at a high point, the standard of learning and character in the profession in whose behalf it was instituted. The relations of the medical and clerical professions are of necessity intimate. Meeting together in the chamber of sickness, one to heal the disease of the body, the other to comfort and soothe the mind, they are, always have been and always must be joint partners in administering to the deepest wants and most pressing necessities of humanity. You were pleased to refer to my profession as connecting itself with the joyous and the sad events of life. This is true, but equally true of your profession; for if there be nothing more sad or more universal than sickness and death, there is nothing more joyous than birth, a new life in a family—and neither of them takes place without the presence of your profession, to aid the one, and, if possible, relieve or prevent the other. You are in at the birth and death of every individual, and you are liable to be summoned to his help at every step between the cradle and the grave. It is true of my profession, and with a somewhat broader meaning, simply because religion is universal in its influence, and should pervade, glorify and exalt the whole of our being, go with us into every scene, and mingle with every thought and purpose. The world does not recognize this to the extent it ought, and is always ready to find some fault with the exhibition of religion that is made in the life and character, as being too broad or too narrow, too lax or too strict and stern. John, the Baptist, with his girdle of camel's hair, his food locusts and wild honey, and his ascetic mode of life, drew forth the condemnation—"he hath a devil." Jesus of Nazareth, sim-

ple and natural, mingling freely in the social life of his time with all classes, drew forth the condemnation, "a man gluttonous and a wine-bibber." In all professions and callings there are annoyances of this sort, arising from misjudgments and a censorious spirit. The only remedy is for every one to remember that to be a man, a true, honest, and faithful man, is the highest and best thing that any one can be, greater than being a clergyman, or a physician, or any thing else, and set his manhood above his profession or calling, and carry it with him into all the walks of his profession, and he will be happy and useful.

Mr. Chairman—I need not say, sir, that I honor the medical profession, honor it in its history, character, purpose, honor it in the names of the many good, noble and devoted men who have adorned its annals from the earliest times, honor it in the progress it has made in anatomical and medical science, in the discovery and application of remedies for disease, and in all that it has thus done to relieve human suffering, prolong human life, and to add to the sum of human happiness. No profession or calling in life, I suppose, Mr. Chairman, is to be unduly exalted as absolutely and in itself more important than any other, for all, however we may distinguish them as highest or lowest, all are dependent one upon another. What Paul says of the human body, "that the eye cannot say unto the hand I have no need of thee, nor again the head to the feet I have no need of thee," that we have many members but one body, and every member alike important in its place and office, is true of society—and of the members of society, they that seem the least are often as important to the grand result as they that we call the greatest. I was crossing the Atlantic once, when the engine was suddenly stopped, and the little floating world on board the steamer were in some consternation to know what was the trouble, and we were informed that a little nut that held a screw or bolt in its proper position had worked off, and it was necessary to replace it. That little nut, apparently a most insignificant part of the machine, in its right place, doing its right work, was as necessary to the safe and successful action of the engine as the main shaft. Society is a great machine, and the most lowly and obscure portions, doing their work faithfully, are as important and useful to the right action and result of the whole, as the most distinguished and exalted. Life or death hangs upon the skill, the knowledge, the steady mind and steady hand of the surgeon

in performing some nice, delicate, dangerous surgical operation. He performs it successfully, and rightfully gathers gratitude and honor. But he could not have performed it without his instruments, and without their being of the right kind, well made and perfectly reliable; and for them he is dependent upon various obscure persons, from the miner who dug the ore and the workman that tempered the steel, to the accomplished artisan who gave the last touch of keenness and polish that made the instruments fit for surgical use. Social life abounds everywhere with illustrations of this kind, and if this mutual dependence of each upon all, all upon each, were felt and understood, there would be less of pride and envy and discontent, more of honest manliness and mutual respect—in short, a more Christian Commonwealth. But as "health is the poor man's blessing and the rich man's boon"—as no man can do anything, save as he is well and strong—in body and in mind, the profession whose purpose it is to guard and promote health and strength, may claim a very high rank among the elements that enter into and determine the measure of human happiness; and so I give you, Mr. Chairman, this sentiment:—

*The Medical Profession*—Its usefulness, the learning, the skill, the care, the fidelity of its members, give a claim to honor, reverence and gratitude which no intelligent community will fail to acknowledge.

The reader need not be told that the following motto was pronounced in honor of Dr. Jacob Bigelow:—

*"Nature in Disease."*—No better illustration of the power of the doctrine can be found than the still hale and hearty life of its great exemplar, the *Nestor of the profession*.

Dr. Bigelow not being able to be present, we were favored with this letter:—

Boston, June 1, 1869.

MY DEAR SIR,—On my return last evening from a journey of four weeks, I found your very kind letter of May 26th, inviting me to attend and assist at the annual festivities of the Massachusetts Medical Society.

Much as I should be delighted to be present at this re-union of our time-honored Society, I regret that the engagements accumulated during my absence render it impossible for me to be present at the necessary hour.

Every one who travels, and every one who stays at home and reads, must be satisfied that the world is now eminently in a

transition state, and that in this revolution of things our own country is taking the lead. The obsolete studies which have for preceding ages consumed the most susceptible period in the lives of our youth, are being replaced by more solid and practical sciences and arts, equally useful as discipline for the mind and far more remunerative in substantial benefit to mankind.

The progress which we trust the science that we ourselves represent is undergoing at the same period, is to be found in the preponderance of the *science* of medicine over the *trade* of medicine, and in identifying the interest of the physician with the interest of his patient. The mysterious charlatanry of former ages, the pretence and assumption of unlimited power over disease, the covering up of our unavoidable shortcomings with a fog of technical forms and unintelligible language, are things already of the past, as far as enlightened physicians are concerned. Rational medicine is beginning to inform the profession and the public in regard to the true powers of the healing art. The community are beginning to be undeceived and reeducated so far as to know what is true and trustworthy from what is gratuitous, unfounded and fallacious. And the profession themselves will proceed with confidence, self-approval and success, in proportion as they shall have informed mankind on these important subjects, and in proportion as they shall understand their own powers, profess simply what they can accomplish, use rightly their immeasurable power for good or for evil, and do to those who are committed to their charge what they would wish should in like case be done to themselves.

Your friend and serv't,

JACOB BIGELOW, M.D.

To J. BAXTER UPHAM, M.D.,

*Anniversary Chairman.*

The Chairman now said—

It is sometimes charged against the medical profession that in the courts of law they are the worst witnesses and the most refractory subjects that the bench and bar are called upon to deal with. Now I look upon this as a libel, and I call upon that staunch and eloquent representative of the law, Judge Devens, to refute the slander.

Judge Devens delivered a most charming address, in which he maintained that the same qualities necessary to make a distinguished physician were necessary to make a distinguished judge.

Prof. Samuel Eliot, LL.D., was called up by the following sentiment:—

*Medicine in its relation to Art and Litera-*

*ture.*—One of the best historical sketches of the leading men of the Massachusetts Medical Society in the last century was from the pen of Dr. Ephraim Eliot, and may be found in the printed proceedings of the Massachusetts Historical Society for 1863. Whether the medical writer was a blood-relation to the well-known historian of our day I cannot tell; but on the score of his distinguished literary and æsthetic attainments, we shall claim him as one of the sons of "old physic."

Prof. Eliot responded in a burst of oratory which those who have heard him can imagine, but which we cannot describe.

At the close of Dr. Eliot's address, Dr. Upham rose and read the following remarks:—

*"The Science of Modern Practice and Therapeutics*—It cannot be better shown than by contrast with the usages of our worthy ancestors a couple of hundred years ago. I have here a prescription sent by a famous London physician to John Winthrop, Governor of the Colony of Massachusetts Bay, A.D. 1643. It is called 'a remedie against fevers, poysons, smallpox, the plague, and such like'; and is as follows: *R.* In the month of March take Toades, as many as you will, alive: putt them into an earthen pott: cover it e a broad tyle; then overhelme ye pott, so ye bottom may be uppermost; putt charcoales round about it, and in ye open ayre, *not in an house.* Sett it on fire; when cold take out ye toades and in Iron mortar pound them well and *tearce* them (whatever that may be) —a black powder will result. Of this you may give a dragme inwardly in any infection. For prevention  $\frac{1}{2}$  a dragm will suffice. Moderate the dose according to ye strength and constitution of ye partie."

As if to enforce the contrast here alluded to, Dr. Upham then turned to a distinguished guest on his right—who is one of the shining lights of modern science—and said:—We have with us a distinguished representative of the profession from the city of New York—well known to you all by name and reputation—to whom personally and to the noble body of co-workers with us in that great city, we are happy to extend a cordial greeting. I have the pleasure to announce the presence of Dr. Edward R. Peaslee.

Dr. Peaslee honored us with a highly interesting and forcible address.

The other sentiments were—in the order in which we find them reported—The Organ of the Medical Profession in New England, responded to by the Editor of the

Boston Medical and Surgical Journal; The Delegates from other States, by Dr. Joseph C. Hutchinson; The Orator of the Day, by Prof. Munroe, on behalf of Dr. Hitchcock; Psychological Medicine, by Dr. Tyler, of Somerville. Dr. Tyler said:—

"I thank you, Mr. Chairman, for placing so high an estimate upon psychological medicine. I thank you for the honorable way in which you speak of the dear old institution which it is my honor to have charge of, and for the flattering personal reference, which latter I well know springs in great part from the life-long friendship and partiality which you have never failed to extend to me. Gentlemen—brethren—Difficult and delicate as psychological medicine is, I believe it is better understood in its theory and practice to-day by the great community of New England physicians than it ever has been by them or by any equally large body of medical men in the history of the world.

It is through you, my medical brethren, as much and more than by hospital superintendents, that the community is, or ought to receive its proper instruction in psychological medicine—that is, concerning the proper care and treatment of the insane.

The moment a person becomes insane he requires the care of others; he becomes in a sense a public charge.

If you do not show the public the right way to treat him, others will—and there can be no worse mistake than to leave this important duty to a politician; there is too much affinity and kinship between the two characters to make this a safe operation; it is worse than the blind leading the blind, and the two will be likely to end in worse than a ditch!

The community is full of false notions concerning the nature of insanity and its necessities, and to you it belongs in a great measure to correct them. But, gentlemen, I know you do not want to hear a speech at this late hour, and should I undertake to go on, I fear me you would think that I was delivering a clinical lecture on insanity, with demonstrations from the patient. Only one thing I do wish to say, because here, to a body of high-minded, intelligent physicians, is the place to say it.

The practice of psychological medicine, that is, the care of the insane, comprises their custody and their curative treatment. All require the former, but not all the latter. In other words, all the people in the State who to-day are insane need supervision; for but a small number, however, would *curative* treatment be of any use.

A part of the insane who may be rich can be taken care of very much as other sick and dependent people are—at home, in private families at large. But the insane poor *all* become a public charge, and, with every phase and variety of the malady, are congregated in our State Hospitals; and many of these, Dr. Bemis told you yesterday, do not require hospital treatment, and would be happier and better off elsewhere than in hospitals. But there is no other place for them. In what manner these people, dependent upon the public for every care, can best be provided for, humanely and consistent with proper economy, is the great question of the day in this department. Now this mere custody is very different from the necessities of *curative* treatment. And this I beg you to explain to every one you meet. To many requiring only custody large liberty can be given; and for them different constructions from our large and expensive hospitals might be as well. But the necessities of those who require curative treatment are entirely different; and what they do require is as well settled as any fact in medicine, having been proved by thousands of successful results in every civilized land. The prominent requisites are separation from home and familiar persons and associations, occupation of the mind upon subjects which it can handle in a healthy way, and every attention to the always existing physical disorder; and this to be continued until the mind regains its poise and self-control.

From confounding the mere requirement of custody and the absolute necessities of curative treatment, have arisen much of the misunderstanding and irritation in the community concerning the care of the insane. If you can, and I believe you can, make this matter better understood, you will do a very great moral as well as professional service.

The proceedings were closed by the singing of Auld Lang Syne.

Our readers are now in possession of what Prof. E. H. Clarke pronounces the best monograph on ergot extant.

WE call attention to the advertisement of Dr. Amory. The study of the action of drugs, by practical experiment, is, in our opinion, that branch of medical investigation which now promises the most satisfactory harvest; and which is to put scientific therapeutics on such a basis as it has never before had.

## Medical Miscellany.

THE following extract from the Boston City Registrar's Report was crowded out from our last issue:—

"Physicians.—Another serious evil\* is the indefinite nature of the certificates of deaths made out by some physicians. This fact is one of more consequence than those delinquents seem to attach to it. This complaint would not arise in the majority of cases if physicians would, when possible, state the primary and secondary causes of death. For instance, coroners (those who are physicians) will say, in a given case, "death from poison," without specifying whether death was the result of an accident, or was self-inflicted. It is important, in every point of view, that it should be determined whether the case was one of suicide, homicide, or was accidental. Again: one physician states that a woman died of peritonitis, without using any qualifying term to distinguish its essential character. The death may have been the result of an accidental injury; or it may have resulted from childbirth; or it may have been murder. The facts are of value not only to the few, but are such as concern the whole community. If vital statistics are worth anything, they should be made to express all that concerns the health and well being of every individual. The same objection lies against a large number of cases where death is said to have been caused by inflammation of the brain, bowels, or other parts of the body. Hemorrhage is another term frequently used, and often conceals what it is desirable should be made known.

"Many of the deaths recorded in the City Registrar's Reports each year, as resulting from accidental causes (with the exception of those occurring in the hospitals), have been designated in the physicians' certificates in the unsatisfactory manner alluded to above. Those deaths were known to have been accidental ones through other channels, and, therefore, were so classed. The record alone, however, will not show that some were not homicides, and others suicides. Until physicians, therefore, shall express the cause of death in the way above indicated, and as the registration law obviously requires, the whole system, so far as it concerns the records of deaths (than which no subject is of more importance to the whole community), will fail in its most essential features, and prove, to a certain extent, practically useless."

[We leave comments to those who choose to offer them.—Ed.]

A SLIP giving the report of deaths in the city of Providence, R. I., during the month of May, 1869, has been sent us with the following passages marked:—

"There were two murders in the month of May, which are only counted in the above table as one death, under the head of *criminal abortion*. The victims were a young, healthy married woman and her unborn child. From some foolish reason, at any rate with no good and sufficient reason, she consented to do violence to the laws of her being, to prevent the high object of the marriage rela-

tion, and to become accessory to the murder of her own offspring. In so doing she lost her own life. It would be well if her death might be a warning to others, and if all would remember that this crime can never be done with safety. It is always murder of one human being; there is always possible danger to the life of the mother; there is always certain injury to her health and happiness.

"The murderer in this case received twenty-five dollars for his services in killing two human beings. He assured the deluded woman that there was no danger, but exacted from her a solemn promise that "whatever might happen, she would not tell any one of his crime. \* \* \*

"EDWIN M. SNOW, M.D.,  
Superintendent of Health and City Registrar."

**RAPID CHANGE OF COLOR IN HUMAN HAIR.**  
*Mr. Editor.*—The possibility of the bleaching of the whole hair of the head in one night *was fully established* by a case which occurred under the observation of Dr. Landois, of Greifswald, in 1866. An account of it was published in the JOURNAL of August 30th of that year. The change of color was not due to the disappearance of the pigment, but to the presence of minute air-bubbles within the cortical and central portions of the hair.

The sudden change from black to white in single hairs reported in your last issue, was probably due to the same cause. It may be that this change in Dr. Brown-Séquard's case did occur only in the night, but some recent observations of Dr. Landois in a case of intermittent blanching show that the process is not necessarily nocturnal.

### CASES IN AURAL PRACTICE.

By J. ORNE GREEN, M.D., Physician to the Department for Diseases of the Ear, Boston City Hospital.

*Collapse of the Membrana Tympani from the Pressure of Cerumen.*—Mrs. T., aged 30, reports that for some years she has had an occasional deafness in the left ear, which she attributes to cold. At such times the ear felt "stopped," and this sensation and the deafness were often relieved by pulling or rubbing the auricle. One week ago, during a cold, she again became deaf in the left ear, and ever since she has had a disagreeable feeling of pressure on the left side of the head, without actual pain. The hearing of the right ear is slightly affected. On examination, both passages contain masses of cerumen; the watch is heard, r. 36", l. 3": the voice r. nearly normally, l. 4'. The syringe easily removed the mass from the right meatus, increasing the hearing for the watch to 48": from the left meatus a considerable quantity of cerumen was removed, and the hearing for the watch increased to 6", for the voice to 8'. Examination now showed the left meatus free, except close to the mem. tym., where there was a layer of dried cerumen, which obscured the view. She was directed to use an alkaline instillation for two days. The remaining cerumen was then easily removed, and the mem. tym. seen to be thickened in its dermoid layer and very much sunken, the manubrium lying nearly horizontal; the hearing was only slightly improved, although the ear felt clearer. Politzer's air-douche restored the membrane to its normal position, and she immediately announced a perfect restoration of the hearing and a sense of clearness and lightness in the head which she had not felt for many months. The watch was heard 24" on that side, and the voice equally well in the two ears. Was directed to inflate the ears by Valsalva's plan once a day for one week.

Various changes can be produced in the ear by a mass of cerumen, and any one who

has seen many cases will be exceedingly cautious in promising improvement merely from the removal of the offending mass, as it is often necessary to treat the ear for some time to remove the effects of the pressure and irritation. If the mass has been forced down upon the drum and has remained there for some time, the mem. tym. may, as in the preceding case, be forced inwards against the promontory and there remain, either by the cohesion of its mucous surfaces or by the contraction of the musculus tensor tympani and of the ligaments of the ossicula. In some of these cases the elasticity of the tissues is sufficient to restore the parts to their natural position; in such the patient does not get immediate relief from the removal of the mass, but a few minutes afterwards the hearing is suddenly restored with a snap as the two surfaces separate; in others the air-douche, either by the catheter or by Politzer's plan, is necessary to restore the natural position, and sometimes this has to be repeated a number of times to counteract the secondary contraction of the muscles and ligaments, especially in those cases which have been in this condition for a long time. Another effect of the irritation is a thickening of the dermoid layer of the mem. tym. and the development of large quantities of epidermic scales; these scales are sometimes packed in dense layers, and require to be softened before they can be removed, and even after their thorough removal may continue to be formed and thus again close the meatus enough to interfere with the hearing. We sometimes find after the removal of a mass of cerumen that the drum is very much injected and swollen, more so than the syringing could account for; and in one or two cases I have found an abnormal quantity of mucus in the tympanum, the irritation having produced a sub-acute catarrh of the middle ear; this sometimes comes on gradually, without pain; sometimes, however, causes a sharp, but short earache. In these cases the air-douche is of great and immediate benefit, the pain often disappearing after the first application.

Vol. III.—No. 21

[Whole No. 2156.]

*Granulations covering the whole Membrana Tympani.*—M. M., aged 5½ years, a pale, debilitated girl, with ulceration of the cornea, sent to me by Dr. Williams. Eighteen months ago, without known cause, her right ear began to discharge; this has continued without intermission; there is great itching in the ear, which keeps her awake at night, and causes her to continually scratch it; no pain, except on pressing the auricle. Some months ago used an astringent instillation for some time without benefit.

On examination the auricle is red, swollen, misshapen and in many places excoriated; the skin of the meatus is inflamed, covered with granulations, and so swollen as completely to close the passage; the whole surface exuding a thick and very offensive pus.

Watch heard only on being pressed against the auricle, and the voice only at about three feet. Throat healthy. Submaxillary glands enlarged.

It was directed that the ear be syringed three times a day with lukewarm water; small sponge tents were inserted every other day, and the meatus painted with a solution of nitrate of silver ʒi. ad ʒj. After the use of the tents for a week the swelling of the skin was so much reduced that the deeper parts could be seen; the mem. tym. was then found to be a mass of firm granulations projecting far into the meatus, and almost insensible to the touch, even when considerable force was used; all the anatomical landmarks were obliterated; the deeper parts of the walls of the meatus were also granular. By Politzer's air-douche no movement of the drum was observed, and nothing was felt by the patient. The dilatation of the meatus had improved the hearing slightly, the watch being heard at 1'.

The granulations were now touched every other day with the solid nitrate of silver, the syringing continued, and an astringent solution instilled after each syringing; at first a solution of acetate of lead (gr. vi. ad ʒi) was ordered, but afterwards nitrate of silver (ʒss. ad ʒi.) was painted on. A sponge tent was occasionally inserted to hasten the resorption of the thickened skin. Under this treatment the improvement was steady, the thickened skin of the auricle and meatus became normal and the meatus assumed its natural size, the granulations diminished in size, the discharge ceased, and the hearing improved. I then ceased treatment for some ten days, thinking that the parts might continue to improve, but

the discharge returned in small quantity, and the above caustic treatment was continued, the applications being made less frequently. As the mem. tym. became thinner, the air-douche by Politzer's method was used frequently, and at the end of three months the meatus had become perfectly smooth and normal, and the thickening of the skin had entirely disappeared. The membrana tympani was whole, of nearly normal thickness throughout, but slightly more opaque and more concave than natural; the hammer distinctly to be seen with the manubrium drawn inwards and appearing foreshortened; no discharge or feeling of discomfort. The hearing much improved, the watch 15" and a low whisper at twenty feet. One month afterwards all the parts remained in the same condition, no signs of a return of the trouble.

When the case came under observation, we had the results of a neglected otorrhœa to deal with; it was impossible to state what the original trouble had been, but it was probably either a diffuse external otitis or a myringitis, and, being neglected, the inflammation became chronic, and extended itself till finally the whole meatus was closed by the thickened and granular state of the walls. The case is interesting as showing what can be gained by persistent and appropriate treatment.

*Otitis Media, with Perforation.*—A. L., æt. 50, engraver. Some eighteen years ago had an eruption on head, face, in ears and nose, which he considered due to the fumes of white lead. At that time had a discharge from the left ear, which continued for several years and then ceased.

Two weeks ago was ill with what the attending physician said threatened to be typhoid fever, but after four days' confinement recovered. During this illness the throat and the track of the left Eustachian tube were quite sore, but he denies any severe pain in the ear. The ear very soon began to feel full, with a loud singing and whistling noise; all of these symptoms have continued without diminution, and he complains particularly of the noises, which prevent the mental application necessary in his work. About the time that the noises began, he noticed a slight discharge from the meatus. Now the left meatus contains a quantity of thin muco-purulent discharge, with much loose epidermis; wall of meatus excoriated in several places and red near the drum. The left membrana tympani uniformly swollen and red, so that none of the anatomical peculiarities, as manubrium and small process, can be seen.

Right membrana tympani has a crescent-shaped thickening in its posterior segment, but is otherwise normal. Watch, r. 48"; l. 3". Mucous membrane of throat and nose slightly inflamed. By Politzer's air-douche a distinct perforation-whistle is heard in the left ear, and he announced an increased clearness in the ear and a diminution of the noises. A chlorate of potassa gargle and an instillation of sulphate of zinc were ordered. One week later, reports the head much clearer, noises greatly diminished in intensity, discharge less. Watch, l. 6". Membrana tympani very much sunken, generally gray and opaque; along manubrium, however, still red and swollen; a perforation,  $\frac{1}{2}$ " in diameter, distinctly seen on the anterior segment. Politzer's air-douche brought the membrane out into its normal position; and immediately after, the watch was heard 15", the noises ceased entirely, and the feeling of pressure in the ear was wholly removed. To continue instillation.

Ten days after, the discharge had entirely ceased, the perforation had healed, so that not even the cicatrix could be seen, and the only trace of disease was a slight thickening of the membrane. The watch was heard at 48", equally in the two ears.

*Otitis Media, with Perforation.*—McN., æt. 9 months. An anæmic child; has for some weeks had a thick, purulent discharge from one ear; has been very irritable, and at night restless, continually scratching the affected ear. On examination, the meatus was swollen, excoriated from scratching, and filled with a thick, muco-purulent discharge, which was removed with the syringe, and the membrana tympani was then seen to have an oval perforation about  $1\frac{1}{2}$ " in its longest diameter, just below the end of the manubrium; through this perforation the air could be forced from the nostrils. Under the use of astringents, strict cleanliness and the occasional use of Politzer's air-douche, the discharge ceased, all signs of inflammation and irritation in the meatus disappeared, and at the end of three weeks the perforation had healed perfectly, not even leaving the relaxed cicatrix so often seen. It was impossible to test the hearing power on account of the youth of the child, but the ear appeared as well as the other.

*Otitis Media, with Perforation.*—Dec. 8th, 1868. E. S., æt. 6. A strong, healthy boy. Last summer had the measles, during which he suffered once or twice from earache. Three weeks ago, a mild scarlet fever; ten days ago, severe pain in right ear, which

lasted one night, and did not return till Dec. 5th, when the pain became very severe in right ear and right side of head. This continued about twenty-four hours, and then ceased on the appearance of a profuse discharge from the meatus. On examination, the membrana tympani was inflamed; so much swollen that no trace of the hammer was to be seen, and on the anterior segment was a perforation one fourth the size of the whole drum. Throat inflamed, tonsils enlarged and submaxillary glands swollen. By Valsalva's plan, there was a loud perforation whistle. Watch, r.  $\frac{1}{4}$ "; l. 60". A weak astringent instillation was ordered, and an iodine gargle, together with frequent syringing and Politzer's air-douche every other day. The pain in the ear returned two or three times, less severe than at first, but was always relieved by the air-douche forcing out the mucus and pus which had collected in the middle ear, and which caused painful pressure. The discharge gradually diminished, and the hearing improved after each air-douche, till, on the 17th, less than a fortnight after the perforation took place, the perforation was perfectly healed, the discharge had ceased, and the hearing had improved so much that the watch was heard 18", and the voice equally well in the two ears. Four months after, the hearing was perfectly normal, and there had been no return of the earache.

*Chronic Purulent Catarrh, with Perforation on one Side; Chronic Simple Catarrh on the other.*—July 10th, 1868. K. M. T., æt. 13, sent to me by Dr. Williams. A healthy, but not very robust girl. Five years ago, scarlet fever; since that time has had a purulent discharge most of the time from the left ear, and has been subject to frequent pain in right. During a cold in the head, to which she is particularly liable, usually quite deaf, but the deafness has always passed away with the cold; last February, however, during a cold, became deaf, and has so remained without any change. Now, there is a slight purulent discharge from the left ear; after its removal, the membrana tympani was seen thickened and perforated anteriorly and inferiorly; Politzer's air-douche, however, gave no perforation-whistle. Right membrana tympani drawn inwards, small process projecting, the anterior and posterior folds running from the small process very prominent. Throat generally red; follicles and tonsils much enlarged. Watch heard, right 3"; left  $\frac{1}{2}$ ". My ordinary voice, three feet. After Politzer's air-douche, r. 12"; l. 1". Was ordered to syringe the left ear

twice a day, to use an instillation of sulphate of zinc for that ear, and an iodine gargle.

July 13th.—Improvement in hearing lasted till last evening; now, watch, r.  $3\frac{1}{2}''$ ; l.  $1''$ . Discharge diminished in left. Last evening, after exposure to cold in an open wagon, earache in right for some time. Air-douche, which improved hearing to r.  $12''$ ; l.  $2''$ .

15th.—Watch, r.  $6''$ ; l.  $1\frac{1}{2}''$ . After air-douche, r.  $18''$ ; l.  $3''$ . Discharge from left much less.

17th.—Watch, r.  $12''$ ; l.  $2''$ . After air-douche, r.  $18''$ ; l.  $3''$ . Small quantity stringy, muco-purulent discharge syringed from left; perforation seemed to be cicatrizing from the edges. Tonsils painted with tincture of iodine.

21st.—Watch, r.  $12''$ ; l.  $2''$ . After air-douche, r.  $18''$ ; l.  $5''$ .

24th.—Watch, r.  $6''$ ; l.  $2''$ . After air-douche, r.  $16''$ ; l.  $3\frac{1}{2}''$ . Throat improving, and again painted with tincture of iodine.

27th.—Watch, r.  $14''$ ; l.  $2''$ . After air-douche, r.  $24''$ ; l.  $5''$ .

31st.—Air-douche again.

Aug. 4th.—After air-douche, watch, r.  $36''$ ; l.  $6''$ . Reports that discharge has ceased; but, on examination, left membrana tympani is covered with a purulent discharge, after the removal of which the perforation is found to be still smaller by growth from the edges.

8th.—Watch, r.  $36''$ ; l.  $5''$ . After air-douche, r.  $36''$ ; l.  $18''$ . Perforation only  $\frac{1}{2}''$  in diameter. Throat very much improved; superficial ulcerations almost healed, follicles reduced to natural level, tonsils not more than one quarter the size they were at first.

12th.—Watch, r.  $60''$ ; l.  $5''$ . After air-douche, r. same; l.  $18''$ . Perforation still smaller; now, merely size of a pin-hole, and membrana tympani less thickened. Throat looking well.

The instillation and Politzer's air-douche were continued occasionally for a month longer, at which time the discharge had entirely ceased, the perforation had completely healed, and the hearing was normal in both ears. Now, some seven months, the father reports that the hearing remains perfectly normal, equal in the two sides, that there is no discharge, and that "she hears as well as any child."

I have placed these cases together to call attention to the complete restoration of the drum, a fact which is too little known, the patient with a perforation being too often told that it is irremediable and should be

let alone. In the last case, the perforation had existed for nine years, and showed no disposition to heal; on the contrary, the other ear had become more and more affected, till, finally, the deafness had become constant, and yet the result was a complete cure of each ear. They all also show the beneficial effects of the air-douche to relieve the pain caused by the pressure of the collections in the middle ear, to cleanse the tympanum and to restore the membrana tympani to its natural position, and thus prevent the formation of adhesions and clumps of mucus, which would interfere with the vibratory power of the ossicula; in the last case, it is certain that nothing else could have saved the child from permanent and extreme deafness. In the two following cases, the drums had been so completely destroyed that nature could not repair the loss; and yet by a simple mechanical contrivance it was possible to improve the hearing so much that neither patient would have any great difficulty in the ordinary affairs of life.

*Complete Destruction of both Membrana Tympani; an Artificial Drum applied with benefit.*—Dec. 21st, 1868. I. C., æt. 10. Has always been delicate till the last two years, when her general health has much improved. Once, when a baby, had a slight otorrhœa of short duration.

Six years ago, had a very severe scarlet fever, and during it severe pain in both ears, followed by a profuse discharge from both. The otorrhœa ceased in the left after one year, but has continued in the right without intermission. Two weeks ago, had severe pain in left ear for a short time, followed by discharge, but the discharge ceased in a few days. Is subject to nasal catarrh. The deafness, which was apparent soon after the beginning of the disease, has remained about the same ever since.

There is a decided hereditary tendency to catarrhal affections of the ears, the father, mother and two aunts on the mother's side being deaf.

On examination, the right meatus contained a quantity of muco-purulent discharge and some loose epidermis; the left one, flakes of epidermis so tightly packed that they required to be softened before they could be removed. Both membranae tympani have been almost completely destroyed; on the right side, the hammer is seen very much drawn in, and on each side of it is a narrow strip of membrane which passes round about one third of the tympanic ring, the only remnant of

the drum; beyond this the membrane of the tympanum is seen, red and swollen. On the left side no trace of the membrana tympani is seen, but a thin cicatrix has formed from the promontory to the anterior edge of the tympanic ring; the ossicula not to be distinguished. The right Eustachian tube was impervious, the left slightly pervious. The watch was heard on the right side only on contact, on the left only very faintly on being pressed firmly against the ear; the tuning fork on the forehead about equally in the two ears; my ordinary voice only 3' in the right, the best ear.

Frequent syringing and astringent instillations were ordered for the right ear, in order to diminish the swelling and check the discharge; after their use for two or three weeks, the swelling was so much reduced that air could be forced through the Eustachian tube by Valsalva's plan, and the discharge had begun to diminish. At the end of two months, the Eustachian tube being perfectly free and the discharge having ceased, I applied an artificial drum in the right ear. First testing the hearing, I found that the watch was heard 1", the voice 5' on that side. I then cut from a piece of sheet rubber, about one third of a line in thickness, an oval somewhat smaller than the natural drum; through the centre of this a thread was passed, and the thread passed through a silver tube and drawn tight, so that the bit of rubber was held firmly against the end of the tube. The artificial drum was then passed in till it rested against the hammer and remnant of the natural membrane, and occupied nearly the position of the latter. The tube being now withdrawn the rubber was left in this position, and there was found to be an immediate and decided improvement in the hearing. The watch was heard some 5", but the voice more than 25", and all external noises exceedingly loud.

She was furnished with a tube, and instructed in the application of the drum, so that after a few trials she could get it into very fair position herself; was then directed to apply it daily, gradually increasing the length of time that it was kept in, till it could be borne all day. A few days after, she reported that while the artificial drum remained in she "could hear everything"; she found some little difficulty in adjusting it herself, but I encouraged her to persevere, and have no doubt that she will soon learn to adjust it properly and quickly.

*Complete Destruction of both Membrana Tympani; Application of Artificial Drums*

*with great benefit.*—II. P. T., æt. 29. A fine, healthy man. When 4 years old, scarlet fever, and ever since a continuous, offensive otorrhœa on each side. On examination, the right membrana tympani is entirely destroyed; the hammer remains, very much drawn in, and just below it the mucous membrane of the tympanum is red, irregularly swollen, and in one spot a white mass of calcareous deposit is seen and felt on it; right Eustachian tube pervious. The left ear exhibits almost the same appearances, except that the membrane of the tympanum is perfectly smooth and of a light pink color; no remnants of the membrana tympani to be seen; by Valsalva's experiments, there is a distinct perforation-whistle. The watch is heard 1" in each ear; the voice about 5'.

Under the use of an iodine instillation, the swelling was so much reduced in the right ear that he could blow air easily through it; the otorrhœa was diminished by the astringent, and finally checked by the use of talc.

Artificial drums were then applied to each ear in the same way as in the preceding case, and to his great gratification his hearing was greatly improved, so that he could easily carry on a conversation with a person twenty feet distant. He was taught to introduce them himself, and before he left for his home in the west could adjust them easily, and with great benefit to the hearing.

#### ON THE USE OF RUBBER CLOTH IN THE TREATMENT OF SKIN DISEASES.

By Prof. HEBRA, of Vienna.

Translated for the Journal from the Archiv für Dermatologie und Syphilis. By JAMES C. WHITE, M.D.

DURING my last visit to Paris (September, 1867) Prof. Hardy told me that he frequently used vulcanized rubber cloth (*toile caoutchouée*) in the treatment of eczema with good effect, applying it "*pure et simple*" upon the affected parts. As there happened to be no case at the time in Hardy's clinic to illustrate its use, I was obliged to be satisfied with the information alone, and to undertake an independent examination of its effects on my return. This I have been doing for the last year, and would now make known the results of such treatment.

It was to be expected *a priori*, considering the impermeability of caoutchouc to watery liquids, that the evaporation of the volatile secretions of the skin would be prevented, and their collection in the form of

drops between the rubber cloth and the skin favored by its application. Now as every liquid, including the normal secretions of the skin, tends to soften and macerate the epidermis by long contact, it was principally the therapeutic effect of such maceration that was to be looked for here. It was, therefore, a continual warm bath in the individual's own cutaneous secretions which was used upon the affected parts, and it might be expected the results would be similar to those obtained by the "continual bath."<sup>\*</sup>

This supposition, however, has been only partially realized, and principally when pure caoutchouc has been used instead of the vulcanized cloth. With the latter there must also be taken into account the materials used in the process of its manufacture, especially the sulphur; so that wrapping a part in vulcanized rubber cloth, to continue the above comparison, might be likened to a continual warm sulphur-bath.

In using this comparison, however, it should not be forgotten that the normal cutaneous fluid secretions differ widely from common water, and moreover that the acids and salts they contain, as well as the fatty matters which are readily converted into the fatty acids by the rapidly ensuing decomposition, exert on long contact with the skin a very different action from ordinary or sulphur water, and that on this account these elements cannot be disregarded in judging of the therapeutical action of caoutchouc. From this point of view as well as from that of experience, which teaches that morbid appearances are often produced upon the skin by the action of its decomposed secretions, I was not disposed to expect any very favorable result from its employment. But on the other hand, as it is well known that the same means which under some circumstances will produce eczema, will under others cure diseases of the skin, I abandoned this overhasty criticism and awaited the results of a careful trial. How far my opinion was justified by the result, will be seen by what follows.

But before mentioning the affections and the individual cases treated by the caoutchouc, I will first describe more particularly the material employed. The rubber cloth (*toile caoutchouquée*) consists of ordinary cotton, which is first coated with a solution of caoutchouc and then submitted to the

process known as vulcanizing. This consists in sprinkling the stuff with a mixture of caoutchouc and sulphur, and exposing it to a high temperature under a pressure of sixteen atmospheres. The material obtained in this way is gray, black or of any other desirable color, flexible, impermeable to watery fluids, smooth and polished on one surface, dull and rough on the other, and smells of caoutchouc and sulphur. Oil as well as all fats, and alcohol, dissolve this layer of caoutchouc, thus destroying its desirable qualities and rendering it useless for the purpose in question. It can be worked like any other cloth, that is, be cut, sewed, and its surfaces be made to adhere by means of a cement containing caoutchouc. These properties led me not only to apply it simply, as Hardy advised, to the affected parts, but I had various pieces of clothing made of it, for instance, caps for the head, bags in which to envelope various regions of the body, gloves, stockings, and finally, entire drawers with and without feet attached, as well as shirts and blouses. Besides these, I had some of the ordinary gum-elastic (not vulcanized) made into bandages and gloves, and convinced myself that this might also be used.

As to the diseases in which I employed it, it will be readily understood that its effect was tried not only in eczema (as Hardy advised), but in many other affections of the skin, especially in cases where it was desirable to soften and macerate dry and hard masses of epidermis, as in psoriasis, ichthyosis, tylosis, pityriasis, &c. In burns of mild degree, also, in variola, and in some cases of pruritus cutaneus in old people I tried the rubber garments, and found especially favorable results to follow.

After this general explanation, we will now describe the individual cases treated by the caoutchouc method, beginning with those of eczema. We have submitted every variety of this affection, from *E. squamosum* to *E. impetiginosum*, to this treatment, making use either of closely applied pieces, roller bandages, or the whole garments. In every case the smooth side of the vulcanized cloth was laid in contact with the skin, from which the collections of morbid products, the scales, crusts, &c., had been previously removed, although in some cases the cloth was applied for the sake of experiment above these. On removing the cloths at the end of 12 or 14 hours they were found very moist, often entirely soaked through, and the fluid, which had collected on the surface of the skin in considerable quantity, of a pene-

<sup>\*</sup> The "continual bath" here spoken of is a method introduced by Prof. Hebra, and used in drum, a fact witnessed and extensive burns. The patient with on water day and night constantly, for two or three months.—TRANSLATOR.

trating smell, worse even than that of the "stinking foot-sweat." The skin itself, however, when cleansed from the diseased products thus softened, appeared odorless and only reddened, more or less robbed of its epidermis, moist and shiny. The sensations of the patient during their application were not at all unpleasant, there being no pain or itching. After their removal, itching generally came on, and, unless they were renewed within a half hour or so, a feeling of contraction and pain also, so that the patients longed for their immediate re-application. If the treatment was continued in this way, the whole series of symptoms gradually diminished—the moistening, redness, itching and pain—and in many cases the cure of the eczema was seen to be complete in the course of two months.

But as it is known that under other treatment the cure of eczema may be effected in this period of time, the question arises what advantage the caoutchouc method offers over others, such as by ung. diachyli, tar, zinc, sublimate, &c.

The answer must be, that, although in general no excessive advantage can be attributed to the caoutchouc, nevertheless there are cases in which this new remedy can be used with especial profit. I refer here particularly to eczema of the hands, fingers, flexures of the joints, scrotum and feet, in which the application of salves, &c., is not only attended by much inconvenience to the patient, but in which also the caoutchouc preparations are able to afford a much more speedy relief to the pain produced by the fissures, inasmuch as such parts can be kept constantly moist by the easy application of the gloves, cots, bandages, suspensories and stockings employed. Although, therefore, no new panacea has been introduced into dermato-therapeutics by the use of caoutchouc in the treatment of eczema, it must still be regarded as a very *valuable addition to our means of cure*, and all the more as it does not prevent the helping use at the same time of other known remedies. Thus in many cases the cure of eczema is powerfully assisted by the simultaneous use of schmierseife, baths, donches, tar preparations, &c., and these latter in turn made more serviceable by the application of the caoutchouc cloths.

Of the other affections of the skin it was especially the hardened concretions of epidermis in pityriasis, xerosis, and psoriasis palmaris, as well as in tylosis plantæ pedis, in which caoutchouc gloves and stockings were successful in easing the pain of their painful cracks, and causing them to heal even

by prolonged use. In some cases of burns of the second degree upon the hands and face we tried the treatment by persistent application of the caoutchouc cloth, and it succeeded perfectly, although I cannot concede to it any advantage over cold or warm water fomentations or applications of ordinary cerate, oil and lime-water, &c. In order to soften the epidermal coverings of the efflorescences in variola, so as to favor their discharge and the absorption of their contents, I tried similar applications of the rubber cloth, enveloping certain of the extremities in rubber bags, and changing them every 24 hours in order to cleanse them and the skin. The course of the pocks was not in the least altered, but the maceration of the thick epidermis of the planta pedis and vola manus thus effected materially helped in preventing the pains which so frequently occur in these localities, and on this account I can strongly recommend this method in variola.

But it was in four cases of general itching of the skin that this treatment was most beneficial, which, although partially associated with eczema, did not occur upon the eczematous parts, and therefore were properly regarded as pruritus cutaneus senilis (prurigo senilis aetiorum). The patients were four old men between 65 and 75 years, one of whom only I treated in the hospital, the other three (Prince F. S., Count Cz., Baron E.) in private practice in connection with their attendant physicians. With all four I had a complete suit of rubber clothing made and worn next the skin, at first day and night. Morning and evening the garments were either changed, or where, as in the hospital, only one suit was provided, this was removed for a short time, cleansed and again put on. The effect showed itself in each case the first day even; perspiration became more abundant, the itching and tension of the skin entirely ceased, and sleep, which had been disturbed, returned. All the patients expressed themselves as much relieved, and submitted with great pleasure to the continued treatment. After the lapse of some weeks the rubber clothing was worn only either during the night or for an hour at a time during the day, until finally it was removed after complete cure in each case. The accompanying eczema was all the more easily treated by the ordinary remedies (tar preparations), as the coverings modified and mitigated the odor as well as concealed the stain they produced. To prevent misunderstanding, let me again draw attention to the fact that the caoutchouc bandages

were of themselves sufficient to allay the distressing itching, which compelled the patients to scratch and deprived them of sleep, and that the tar preparations were only used when sooner or later the ordinary symptoms of eczema showed themselves.

## Reports of Medical Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.  
CHARLES D. HOMANS, M.D., SECRETARY.

FEB. 8th.—*Very slow Pulse, connected probably with Disturbance of the Digestive Functions.*—Case reported by Dr. JACKSON.

The patient was a healthy looking farmer, 53 years of age. For the last twenty-five years or more he had suffered from costiveness, but he had been in the habit of using laxatives, and his general health was sufficiently good. During the last eight years his appetite has been very strong, and it had always been more or less so. Fulness at epigastrium after eating; much flatulence; but no bad taste, acidity, nor rising from the stomach. Sense of weakness, with giddiness, so that he would sometimes fall, unconscious, for a minute or two. Skin rather dry. Urine diminished when he is worst. During this same time the pulse has been slow, often 20 beats in a minute, and sometimes, though very rarely, 16. Once he counted only 6 beats in half a minute; and this was the lowest, so far as observed. Not unfrequently it would rise to 60, or even a little higher; and it sometimes intermits about every fourth beat when it is rising. In character the pulse, he says, is generally full and forcible. Very rarely any pain about the heart. No palpitation. Feels the weakness above referred to, with dyspnoea, on going up hill; and the action of the heart is then increased, but without an increased frequency of the pulse. On examination, the impulse of the heart was not unusual. Sounds muffled and distant, with perhaps a slight systolic soufflé over the ventricles. Pulse 30, moderately full and regular, soon after coming in from a walk; and the same when he had been resting for about half an hour. A few days afterwards, Dr. J. saw this man again. He was then feeling better, and the pulse was rather quicker, and with an occasional intermission. Says that he is quite nervous, though he did not appear so, and that he is still able to do some work. His hands and feet are cold, and particu-

larly when the pulse is very slow; and he is pale when he has his worst attacks.

FEB. 8th.—*Internal Strangulation; Sphacelation.*—Case reported and specimen shown by Dr. J. N. BORLAND.

An Englishman, mason by trade, entered the City Hospital Jan. 24th. He was 40 years of age, and twenty years before had had an attack of what was called "stoppage of the bowels," and recovered after ten days' illness, having ever since been a thoroughly healthy man. Jan 17th, being perfectly well, he ate moderately of boiled beef, and soon after was attacked with severe pain in the abdomen, attended with obstinate constipation and vomiting. Purgatives were given without avail, and blisters, leeches, &c., used externally, but without relief to the pain, till the administration of an enema on the fourth day caused three small dejections, and the pain diminished. His abdomen was much distended, when first seen, and tender on pressure over the epigastrium; there was frequent vomiting; no appetite; great thirst. Beef-tea and brandy enemata were ordered, sinapisms to pit of stomach, and cracked ice for the thirst. During the next three days there was some improvement, less vomiting and less tenderness and distention of the abdomen; there was no dejection, save once a small, insufficient one after an enema of assafoetida.

On Jan. 28th the bad symptoms returned; the pulse became high, the skin hot, and there was delirium, which continued till his death, Jan. 30th. The pain in the abdomen and distress were relieved by hypodermic injections of morphia; the matters vomited were chiefly yellowish or greenish fluids, never any stercoraceous matter.

On dissection, a small, tough, fibrous band was found connecting the intestine and mesentery, about nine inches above the cæcal valve; through the loop thus formed four or five inches of the intestine had passed and become tightly strangulated. Sphacelation was the result, and the intestine had entirely broken through in two places. There was lymph upon the surface of the strangulated intestine to a small extent, but there was no peritonitis, as shown by effusion or fresh adhesions, the surface of the intestines looking only dry and gray in color, with engorged vessels. No other old adhesions were detected.

Dr. JACKSON said this was the first case he had seen of internal strangulation, how-

ever tight, in which there was anything like sphacelation.

MARCH 8th.—*Pleurisy; Jaundice; Enlargement of the Liver.*—Dr. FIFIELD reported the case.

J. S., aged 64, taken sick on Friday, Jan. 8th, 1869. Sent for a physician on the following Tuesday, on account of sputa very slightly tinged with blood, since the previous Sunday. He was found with a pulse of 140, occasional slight breast-pang, slight cough, raising a little scarcely tinged sputa.

Wednesday, the next day, declared himself better, but the pulse remained the same. He was now sweating profusely, deeply jaundiced, raising quantities of thin mucus colored with bile. Percussion dull over nearly whole of right back, normal in left. Auscultation revealed marked bronchial respiration, with ægophony over whole right back, normal respiration in the left.

Thursday.—Pulse 120. Expectoration less; jaundice less; rather more dyspnoea; profuse perspiration; urine scanty, no motion of the bowels.

Friday.—Pulse 140, sweating; more feeble; has had one dejection. Auscultation and percussion same as yesterday. Some crepitus in lower third of left back.

Saturday.—Rather less jaundice; complaints of no pain; no expectoration, slight cough. Pulse 140, skin cold and sweating; a crepitus as of air churned through foam audible at some distance from patient. No pain on pressure over liver. Auscultation shows diminution of bronchial respiration, returning normal respiration faintly heard. Lower third of left back reveals coarse crepitus; percussion dull, slight delirium.

Sunday.—Pulse 140, skin cold and sweating; brown, dry tongue; auscultation shows large crepitus over left back; less dullness on percussion; diminution of respiration in lower third of left back; labored respiration, great efforts to breathe, but not often repeated. Died at 2 o'clock.

Monday, 18th.—Autopsy. Rigor mortis well marked. Skin deeply jaundiced, more than in life. Right chest:—Lung healthy, no effusion, adhesion to costal pleura throughout by soft recent adhesions. Also adherent to diaphragm over liver, and there greatly congested. Pericardium healthy with two ounces of serum. Heart fatty, otherwise healthy. Left chest:—Contained purulent serum one pint; lung not much adherent; recent lymph could be brought up in long strips on sponge. Lung appeared nowhere solid as in pneumonia.

Liver large, smooth, and sufficiently

healthy; left lobe reaching into left hypochondrium; edge of right lobe reaches well below false ribs, but yet cannot be felt from the outside. Gall bladder filled. Kidneys not examined, test of urine being considered sufficiently satisfactory.

Reflections in this particular case are:—

1st, Bronchial respiration heard within three days from commencement of illness, with sputa scarcely tinged, is indicative of pleurisy.

2d, Acute pleurisy may exist without breast-pang, if effusion comes on rapidly.

3d, Jaundice is a bad augury. I do not remember ever to have seen it present in affections of the left lung or pleura, but have seen it appear, when, in affections of the left lung or pleura, the right lung or pleura has been secondarily attacked.

From the autopsy it would seem brought about by adhesion of the lung to the diaphragm over the liver, from sympathy in contiguity in fact.

At the time of the autopsy, I had heard nothing of gastro-duodenal catarrh, hence no examination of those parts was made.

This case seems remarkable, moreover, for the rapidity with which the processes of the disease were carried through. The patient is attacked on Friday, no particular pain, merely feeling ill. On Tuesday, bronchial respiration is heard in right pleura, denoting effusion. On Friday effusion begins to be absorbed, and returning normal respiration is heard in right lung. On the same day disease begins in the left pleura. On Saturday effusion takes place. On Sunday effusion begins to be absorbed, lymph being deposited on the walls of the cavity in coherent masses.

It seems probable that could life have continued, the effusion would have been as rapidly absorbed and adhesion been as complete as in the right pleura. I cannot imagine the crepitation so distinctly heard to have been a friction sound, but, although no expectoration was present, it must have been of the character of a flux from the bronchial mucous membrane, and death must have taken place from an inability to discharge the same—in fact, a capillary bronchitis. Or perhaps it might be spoken of as a paralysis of the lungs, such as we might say produces the well-known death rattle in the trachea.

I hope it will be considered that these reflections apply only to this particular case.

MARCH 22d.—*Recovery from a Wound of the Intestine.*—Dr. JACKSON read a manuscript report of the case by A. A. Surgeon R. G. Jennings, U.S.A., and that was loan-

ed to him by Dr. Wm. H. Hills, of Foxborough. The patient was a soldier who was stabbed by one of his comrades with the small blade of a pocket-knife Feb. 20th, 1866. When Dr. J. saw him, just after the accident, there was collapse, with a protrusion of about two feet of the intestine. It was necessary to enlarge the wound considerably, and there was then found a wound in the intestine, fully  $\frac{3}{4}$  of an inch in length. This occasionally bled freely, though there was no discharge of feces; and, two interrupted stitches having been taken, the ends were clipped close to the intestine, and the mass was returned into the abdomen. On the 25th of March the external wound had entirely healed, a photograph (which was shown to the Society) was taken, and the man was to return to duty in a few days.

Thus far the case, of which the above is an abstract, was published in the *Chicago Medical Journal*, June, 1866. In a letter, quite recently received from Dr. J., he states that after the injury the man had frequent pains in the abdomen, with great prostration; and four months afterwards, on lifting a heavy weight, he felt a "quick snap," fainted at once, with profuse perspiration, and the abdomen became swollen, tender and painful. These symptoms, however, which Dr. J. attributed to a separation of the adhesions that had probably formed, soon passed away; and when he saw him in the spring of 1868, he was perfectly well.

MARCH 22d.—*Singular Mark on the Hand of a Pregnant Woman; appearing at the beginning of successive Pregnancies, and disappearing soon after Delivery.*—Dr. J. P. REYNOLDS reported the case.

L. X., aged 27, confined for the third time on the 27th of February, had on the dorsum of the right hand a nearly circular mark about an inch in diameter, scarcely if at all elevated, of pink color, looking as if formed by a ring of slightly enlarged capillaries; near the knuckles of two of the fingers of this hand were isolated points of similar character. At the beginning of each pregnancy this mark has made its appearance. After every labor, it has in the course of a few days faded and then wholly disappeared. It has become more distinct with each successive pregnancy, the isolated spots showing themselves only during the last.

The patient states that when labor is at hand, the color of the mark deepens to a dark purple. When about seven and a half months advanced in the last pregnancy, she had a dangerous fall down a flight of

stairs, and observed for a day or two following the darkening of the spot above described. The details of this account are confirmed by the husband, and as the parties are people of intelligence, I see no reason to question the accuracy of their statement. I myself witnessed the fading of the mark after the last delivery. Three weeks later the isolated spots could not be seen, and the larger mark was rapidly growing indistinct.

The woman has lost two brothers by phthisis, and is a person of slender make, with light hair and a delicate, irritable skin.

Trifling as this fact is, it seems to be worthy of record. Similar occurrences have been observed by others.

MARCH 22d.—*Anatomy of Prurigo.*—Dr. HASKET DERBY read the following report translated from the transactions of the Imperial Academy of Sciences in Vienna.

*Section of Mathematics and Natural Sciences.*—At a meeting held February 18th, Professor Biesiadecki presented a paper by Dr. Richard H. Derby. Subject, "The Anatomy of Prurigo."

The author arrives at the following results:—

1st, In prurigo there is uniformly a disease of the hair. From the outer root-sheath projects a growth, varying in length, consisting of epithelial cells, and closely united with the root-sheath. It insinuates itself between the muscular fibres of the *arrector pili*.

2d, The *arrectores pilorum* attain an unusual development. Through the increased traction these exert on the hair result, on the one hand, a more vertical position of the hair (goose-flesh); on the other a hernial protuberance of the inner wall of the hair follicle and the outer root-sheath.

3d, A serous exudation takes place in the vicinity of the diseased hair, infiltrating the tissue of the corium and the papillæ, and making its appearance as a clear or slightly bloody drop, on puncturing the papule.

This discovery, moreover, explains the absence of the papules of prurigo in places devoid of hair, such as the hollow of the hand and sole of the foot; and their infrequent occurrence in places almost destitute of hair, such as the flexure of the extremities.

This paper was referred to a commission.

MARCH 22d.—*Syphilitic Stricture of the Esophagus.*—Dr. SINCLAIR reported the case.

W. B. T., æt. 39, teamster. Admitted into City Hospital Dec. 4th, 1868.

*History.*—Has no tendency to hereditary disease. Habits rather intemperate. With the other diseases common to childhood, had scarlet fever, which entailed some deafness, increased of late. While in the army, in the South, had intermittent fever and afterwards acute rheumatism. Had not been so strong since, though able to work regularly until three weeks before entrance, when he began to have dysphagia and regurgitation of food, with a sense of constriction about the gullet, which had increased so as to oblige him to take food and drink in the smallest quantities, slowly and at intervals. Had a poor appetite, did not sleep well, lost flesh, easily fatigued, nervous. Tongue and skin natural. Bowels regular. Pulse 80.

On examination of the throat, the posterior fauces were found in a state of chronic inflammation. Mucous follicles enlarged. No ulceration. Thoracic organs healthy.

Was ordered liquid diet, and five drops of aq. regia three times a day. Two days later, he reported himself as able to swallow better, having increased appetite, and complained chiefly of weakness. Five days after entrance, dysphagia and throat the same. Was directed to inhale atomized sulphurous acid once a day. On Dec. 12th condition of things not improved, and suspecting organic disease, Dr. Cheever was requested to see the patient. A small probang was passed, and a constriction of the œsophagus found, about two inches below its entrance. At the same time, the probability of a history of specific disease in the case was suggested to the house-physician. The stricture conveyed a sense of considerable extent and of elastic firmness, grasped the probang tightly in passing through it, and offered a good deal of resistance in the withdrawal of the instrument. It was subsequently ascertained, on careful inquiry, that the patient had had a sore on the penis two and a half years previous, and an eruption on the skin a year later, for which he had received medical treatment. The following treatment was accordingly instituted:—

R. Pot. iodidi,  $\zeta$ iv.;

Hyd. bichloridi, gr. i.;

Aque,  $\zeta$ iv. M.  $\zeta$ i. 3 t. d.

And probang to be passed through stricture twice daily.

Dec. 19th.—Improving.

21st.—Stricture readily overcome. Swallowed meat yesterday for first time since entrance. R. Quin. sulph., gr. i. 3 t. d.

25th.—Ability to swallow solid food increases.

Jan. 4th, 1869.—Continues to improve. Hears better. Appetite good.

5th.—Discharged, at his own request.

Dr. Langston Parker relates two cases of syphilitic stricture of the œsophagus in his work on Syphilitic Diseases, London, 1860; one occurring in a young woman, another in a man. The woman entered the Queen's Hospital, Birmingham, under the care of Mr. West, in May, 1868, with secondary phagedena of the pharynx, and afterwards, during the absence of Mr. West, was attended by Dr. Parker. She had previously suffered from secondary syphilis. Examination of the throat revealed the cicatrices of a large ulcer on the posterior wall of the pharynx, and by depressing the tongue deeply a portion of an ulcer, which appeared to extend downward into the œsophagus. With considerable difficulty she could swallow cider, but could not swallow milk or beef-tea. There was complete dysphagia occasionally, which continued at one time for thirty-six hours. Every attempt at passing bougie, catheter or probang into the gullet failed. She died exhausted.

*Post-mortem Examination.*—"The upper part of the œsophagus for about four inches was found much dilated; its mucous membrane thickened and marked by spots having the appearance of recent cicatrices. At this distance from the upper end it was suddenly contracted, and terminated in a narrow canal which would barely admit a No. 4 catheter. The contracted portion, which was about  $2\frac{1}{2}$  inches in length, was formed by the thickening of mucous membrane and fibrous bands and bridges, having very much the appearance of an old stricture of the urethra. Below this tract the œsophagus continued perfectly healthy into the stomach."

The other case was that of a private gentleman, under the care of Dr. Parker, and who suffered many years from syphilis and had ulceration of the pharynx. "He was hoarse, tormented with cough and hawking up of frothy mucus mixed with blood; had great pain and difficulty in swallowing." On examination, the whole of the back of the throat was found intensely red; it looked like an old red cicatrix, with here and there white, hard spots disseminated through it; in places, superficial ulcers existed; the whole mucous surface appeared destroyed. He was much emaciated, and looked like a man laboring under organic disease of the lungs; the latter, however, with the windpipe, were healthy. Soon after, the patient left on a foreign voyage, and died, exhausted, on the passage. It is

not recorded whether the gullet was examined in this case; but it is fair to assume, with the author, that this also was a case of syphilitic stricture of the œsophagus.

Follin, in vol. i. p. 696 of his *Traité Élémentaire de Pathologie Externe*, Paris, 1865, says that the greater part of writers on the subject of syphilis say nothing concerning these strictures, or, if they do, it is to deny their existence, and quotes Langston Parker and West as having met with, the former one case, and the latter two cases, of syphilitic stricture of the œsophagus. In his graduation thesis, *Des Retrecissements de l'Œsophage*, Paris, 1853, he quotes three cases which appear to come under this head: the first from Ruysch; the second from Haller, who speaks of having successfully treated a case of stricture of the œsophagus by the use of mercurial pill; the third is an observation of Paletta, who, in a work entitled *Esercitations Pathologiques*, published in 1820, mentions a dysphagia which came on after the suppression of a leucorrhœa and the disappearance of a papulous eruption. But Follin observes that this case, like the others, is very doubtful. Since then, he goes on to say, that he has himself observed two cases of œsophageal dysphagia, which he was able to attribute clearly to syphilis. In one of them there existed a psoriasis of the palm of the hand, and the patient was cured without the use of a probang; in the other the lesions were more profound and the cure incomplete, for there obtained, without doubt, cicatrices, which were ameliorated, but not cured.

Lancereaux, in his elaborate and comprehensive work on *Syphilis*, Paris, 1866, remarks that it is not proved that the oldest writers on syphilis recognized this alteration. Severinus, one of the first, makes mention of syphilitic ulcerations of the œsophagus and the trachea—"Cultro anatomico tradita eadavera variorum syphilide extructorum exhibebant exulcerationes, tum in œsophago, tum in trachea." Rhodius reports a case of œsophageal lesion which he might possibly be right in attributing to a syphilitic origin. A case observed by Daniel Turner (recorded in a practical dissertation on the *Veneral Disease*, 1732), and two more by Carmichael (*Essay on the Veneral Disease*, 1814), are not more conclusive than the preceding. Wilks (*Pathological Anatomy and On the Syphilitic Affections of the Internal Organs*, 1863) recognizes the existence of syphilitic stricture of the œsophagus. An anatomical specimen in the Museum of Guy's Hos-

pital (No. 1784-95) shows, at the point of union of the œsophagus and pharynx, a constriction which had followed a syphilitic ulceration. Virchow describes a stricture of the same kind.

Finally, with regard to the state of things existing in the case observed by myself, it may be inferred that from the manner in which the stricture yielded to treatment the obstruction was caused by a submucous infiltration or gummous tumor, which, if allowed to degenerate, would have formed an ulcer, with subsequent cicatrization and contraction, defying, perhaps, every means of cure.

The short time—three or four weeks—that the dysphagia existed, and the speedy manner in which the case ameliorated after its true nature was ascertained and the proper treatment instituted, show very conclusively the syphilitic character of the stricture.

### NOTES FROM FOREIGN JOURNALS.

*Subcutaneous Injection of Ergot for Aneurism.*—We learn through the *Union Médicale* that Professor Langenbeck, recognizing the hæmostatic property of ergot as proceeding from contractile action upon unstriped muscular fibre, has used the drug successfully in aneurism. He reports two cases to the Medical Society of Berlin. One was a *sub-clavicular* aneurism, the other aneurism of the radial artery. In the first case the Professor injected under the skin three (3) centigrammes of aqueous extract of ergot, in the following mixture:—*Extrait de Bonjean*, 2.5; spirits of wine and glycerine, aa 7.5.

He repeated the injections every three days, increasing the dose gradually, till between the 6th of January and the 17th of February, two grammes had been used.

In the second case fifteen centigrammes of the preceding solution were injected, and the next day the tumor had disappeared. The injections in both cases were made under the skin covering the tumors.

*The Perniciousness of Iron Stoves again.*

—We learn from the *Gazette Hebdomadaire* that on the 3d of May, at the *Académie des Sciences*, General Morin read a summary of various elaborate experiments as to the effects of heating apartments by iron stoves, and also a statement of results. Besides the transmission of carbonic oxide through heated iron, it was found that in rooms warmed with iron stoves the carbonic acid naturally contained in the air, and that produced by respiration, is susceptible of decomposition, and of giving rise to development of carbonic oxide. It was also ascertained that the direct action of the oxygen of the air on the carbon of the cast-iron stoves heated to redness evolved carbonic oxide. It was concluded that heating apparatus of iron without linings of fire brick or of other materials—which linings prevent them from becoming red hot—are dangerous to health. These are but a few, out of many points brought out in the paper as reported in the *Gazette*.

*Pathological Physiology of Icterus.*—A sketch of the Thesis of M. Laborde, on the Pathological Physiology of Icterus, in the *Gazette Hebdomadaire*, opens with the statement that the bile is formed exclusively in the acini of the liver, as we now know positively; and that none of its elements, the principal of which are the choleic and cholic acids, pre-exist in the blood, with the exception of the salts and the fatty matters. This idea puts far out of sight a theory, which is among the oldest, and which attributes certain forms of icterus to a direct transformation of the blood into bile.

We are, at the present day, forced to consider icterus as the result of the diffusion over the economy of a secretory product turned aside from its physiological destination and from its natural channels—a diffusion involving troubles sometimes very grave, by reason of the toxic properties of certain of its constituent elements. In that respect icterus resembles diabetes and uræmia.

In the absence of sufficient data for a different arrangement, we are obliged to abandon attempts at a purely physiological division, and to place the forms of icterus in two categories. In the first are ranked

the cases of jaundice caused by appreciable lesions; to the second, are consigned those of which we have not as yet penetrated to the cause, and which no alteration of the solids can explain. The first category comprehends all the instances of jaundice produced by mechanical obstacles. The bile is partly or wholly absorbed, by the veins and lymphatics; and this absorption requires for its accomplishment from two to forty-eight hours (experiments of Saunders and Frerichs). By the side of mechanical obstacles which are well known—such as tumors, calculi, &c.—are placed passive hyperæmia, which brings about compression of the biliary canaliculi by means of the dilated capillaries (Frerichs); diminution of the lateral pressure of the vena porta; inspissation of the bile; a plug of mucus, &c.

Idiopathic (*essentiel*)\* icterus is that which, consequent upon a nervous shock, has, for its less remote cause, spasm of the biliary ducts; or paralysis of them; or passive congestion. The idea of spasm in this connection is now pretty much abandoned. Paralysis of the ducts leads to *polycholia* and then to jaundice. Lastly, passive congestion of the liver indirectly produced through the influence of the pneumogastric nerve (Séc) would produce jaundice by the mechanism above alluded to.

*Male Fern vs. Tænia.*—Prof. Christison declares the ethereal extract of male fern better than kousso or any other remedy for tænia. He has never failed with it. He gives it in doses of from 18 to 24 grains in syrup or emulsion; and repeats it at the end of a month or six weeks by way of making sure of his work. The worm never comes away alive.

*Cutaneous Diseases.*—M. Guibout asserts, that cutaneous diseases are not merely disorders of the skin, but are, leaving out of view parasitic affections, the expression of more recondite lesions—the outward manifestation of pathological conditions of the general system.

*Ether Spray in the Reduction of Strangulated Hernia.*—M. Chavernac, in the *Marseille Médical*, as we learn from the *Bulletin géné-*

\* The French writer remarks parenthetically that this term serves usually to mask our ignorance.

*ral de Therapeutique*, has been employing ether spray in the reduction of strangulated hernia. He has used it in seven or eight cases. Though the results of these cases are not given, we are told by the *Bulletin* that M. Chavernac draws certain conclusions from them. The anæsthetic effect having been alluded to, he dwells chiefly on the refrigeration produced by the atomized ether, as being much greater and more prompt than that effected by ice. This rapid lowering of the temperature, he says, brings about sudden condensation of the gas contained in the strangulated gut. Hence a diminution of volume, and some possibility of reduction.

*Ranula*.—Dr. Bertin reports in the *Union Médicale* a case of *ranula* of Wharton's duct, in a new-born infant; seton applied; recovery. The infant was seven days old when operated on. At birth the mouth was examined for tongue tic, and nothing abnormal found. When three days old the child nursed with difficulty, and a little prominence was noticed under the tongue. This increased to the size of a small walnut. The diagnosis was *both Wharton's ducts imperforate and distended by fluid secreted after birth*.

Dr. Bertin infers that the salivary glands are dormant till food is introduced into the month of infancy.

Dr. B. unsuccessfully employed the seton for *ranula* in a woman, whom he cured with an iodine injection.

*Singular Case*.—M. Dolbeau, as reported in the *Union Médicale*, presented to the Imperial Society of Surgery a patient affected with a singular and rare lesion. The first instance of the kind was exhibited by M. Léon Labbé a year before. The subject, aged 50, without previous disease, and the cause being unknown; also without pain, suppuration or inflammation, is losing his upper jaw by a process of retrocessive elimination. All his teeth, though quite white and sound, have fallen out; the maxilla is reduced to a triangular shape, with its base directed toward the *velum palati*; and there is a large opening between the mouth and nasal fossie. In M. Labbé's case there was paralysis of the *motores oculorum*. In this patient, with the excep-

tion of attacks of keratitis, and double atrophy of the choroid, the general health has been excellent.

*Podophyllin* is sharing the attention bestowed abroad on *veratrum viride*. The former was tried to a considerable extent by some physicians here in Boston, and is still used by some of them. Others found it very uncertain; sometimes acting extremely well, at other times purging with extreme violence, even to the production of syncope.

*The "Mother" in Vinegar*.—M. Béchamp is quoted by the *Gazette Hebdomadaire* as saying that the *mother of wine vinegar* is a membrane composed of microzmas—either simple or developed into the form of straight or curved twigs—engaged in a hyaline intercellular matter. He likens it to connective tissue in which cells are developed.

PREVENTION OF THE "ABUSE OF CHARITY MEDICINE." *Mr. Editor*.—Some time ago, I called attention, through the columns of the *JOURNAL*, to the "abuse of charity medicine" by persons who were not proper objects of charity availing themselves of the benefits of our free hospitals and dispensaries, to the great detriment of general practitioners and imposition on those beneficent institutions; and I suggested that some course might be adopted, to, in a measure, prevent the evil. Since that time, several additional instances of the kind referred to have come under my notice, and I have reason to believe that scarcely a day passes without some such imposition being practised.

Setting aside the question of the improper drafts upon the public charity, it is a great injury to the general practitioner. It is not the established physician who chiefly feels this leak, but the one just entering practice, who depends almost entirely for existence, during the first few years of his professional life, upon the very class who—shuffling about from physician to physician, seeking for the cheapest doctors—are the most likely to apply for free medical attendance.

It is evidently impossible, in nearly every instance, for the physicians of those institutions to prevent this abuse, for which reason there is the more necessity for the other and more aggrieved party—the physicians themselves—to do something to limit, if not prevent it.

The following, from the pen of Dr. Thos. K. Chambers, published in a recent number of the *British Medical Journal*, is so apposite that I will give it in full, in the hope that its practicable suggestions may be pondered, and, if possible, acted upon in this vicinity.

"Whether," says Dr. Chambers, "the number of people capable of paying who are admitted gratis to hospitals be exaggerated or not, by being viewed through a mist, is of little consequence. If this injustice to the general practitioner be knowingly done in three instances, these are three too many; and my experience of hospital physicians and surgeons in London convinces me they are anxious to avoid it. But the difficulty lies in the detection of cases in point. The exclusion of classes cannot be made; for in every class there are poor and rich, and a professional man and his family are often as proper objects of charity as day-laborers. Neither dress nor manner is any guide, as I have found at the cost of some time and trouble. When I was first a physician to St. Mary's, I used to inquire privately into the circumstances of any inmate I saw superior in these respects to those around them, and in no one instance was I able to detect the power of paying for medical attendance; whereas I was constantly finding, when too late, that miserable pauper-looking individuals had considerable sums of money to be handed over to their representatives. I am quite convinced that no investigation by the hospital authorities can detect the imposture in any who take the trouble to practise it. And if they reject the patient on insufficient grounds they run the risk of an action, which an unscrupulous attorney might make an engine of extortion.

"Would I, then, give up the case as hopeless? By no means. But I would ask the sufferers from the system to put their shoulders to the wheel and help themselves; for here, as in most worldly affairs, lies the best hope of success. Let each practitioner whose paying patients are admitted to a hospital, send to the physician or surgeon under whose care they are placed a formal notice of the fact, and very rare indeed will be the instances in which they are not discharged. I have been physician to St. Mary's nearly twenty years, and I have not met with one yet. Consultants never find it their interest to offend voluntarily the neighboring practitioners.

"The regular attendant does not, perhaps, know of the patients having withdrawn themselves from his care. He is

sure to know all the important cases; and a few examples made of rich persons who have disguised themselves to carry out the imposition, will soon put a stop to the practice altogether.

"I think the notice had best be a printed form, agreed upon by a committee for the purpose, so as to avoid all appearance of private jealousy. It should avoid also the show of an appeal *ad misericordiam*, and make its claim as of right. Until some self-helping step of this sort is taken, meeting and talking and grumbling are of very little use."

W. H. C.

*Boston Highlands.*

WE take great satisfaction in laying before our readers the remarks at the dinner in Music Hall, of Dr. J. C. Hutchison, of Brooklyn, N. Y., one of the delegates from the Medical Society of the State of New York to the late annual meeting of the Massachusetts Medical Society. The manuscript was not received till after last week's issue was in type. But such kindly words as these come "better later than never."

I feel inclined, Mr. Chairman and gentlemen, to adopt the speech of a celebrated English mathematician which I have somewhere read, who, on being called upon to respond to a sentiment under circumstances similar to the present, said, "Mr. President, a morbid desire for originality compels me to say that this is the proudest moment of my life, and it does not occur to me to say anything else." But, sir, I cannot forbear to express the pleasure I have experienced in having been selected as one of the delegates to bear to this Society the salutations of the Medical Society of the State of New York. We in New York have of course read and heard much of Massachusetts Medicine and Surgery, and I was very glad to avail myself of the opportunity which this occasion afforded, to meet face to face those whom we have learned to honor and respect; and although a stranger personally, to most of you, I have realized to-day that the brotherhood of medicine is co-extensive with the limits of civilization.

I have been strongly reminded while attending the meetings of your Society of the time when, two years ago, I represented my State Medical Society as one of the delegates to the International Medical Congress at Paris, and the civilities which have been extended to the delegates from sister societies *here*, are in such striking contrast with the discourtesy which characterized their reception *there*, that I feel inclined, although it is perhaps not in very good taste, to refer to them. Our delegates to Paris, in order to make themselves known and to ensure admittance to the Congress, called at the office of the Secretary M. Jacond with their credentials, and after waiting for some time in the ante-room, were informed by the female

*concierge* that M. Jacoud was engaged, but that we might record our names in a book lying upon the table, and take a green "*carte de membre adhérent*" which was signed by the President, M. Bouillaud, and the Secretary, M. Jacoud, to be filled up by ourselves as we might think proper. The card informed us of the day of the first séance, but neither the hour nor the place was designated; and it was only after a good deal of inquiry we learned that the place was the great hall of the Faculty of Medicine. No cards or certificates were demanded at the door, and we entered with the crowd to find seats for ourselves. Our credentials were *never* examined by any officer or committee. The seats were dirty and uncomfortable, without backs, and the room was excessively hot, and so imperfectly ventilated that it was impossible to remain during an entire session without serious detriment. We were not invited to the hospitals, nor were we furnished with any information with regard to the medical matters of Paris, although we were strangers in a strange city, desirous of seeing the institutions which had given to Paris its professional renown. The Secretary announced a banquet at "Le Grande Hotel," free to all who would send their names with a *Napoleon* to him. The dinner was similar to this, with a few more courses and a greater variety of wines.

The delegates received the most polite attentions from many distinguished members of the profession in Paris, and the foreign delegates were elegantly entertained one evening at the house of our countryman, Dr. J. Marion Sims. But it did seem to us that in the splendid city of Paris, of which Bouillaud said in his opening address, quoting from one of the old French poets, "France is Paris, and Paris is the world," pleasanter arrangements might have been made for the reception of invited guests who were the accredited representatives of the Governments and the learned Societies of the world.

What a contrast to the reception which the delegates from other State Societies have received here! Immediately on our arrival in Boston we were invited to visit four well-appointed hospitals, and witnessed in their amphitheatres the perfection of surgical manipulations. On presenting our credentials to the proper committee, we were at once introduced to your President and to the Society, enjoyed the luxury of arm chairs, instead of benches without backs, and were furnished with complimentary tickets to this sumptuous dinner in this magnificent temple of the Muses, where we have enjoyed at intervals music on the Great Organ, and from accomplished vocalists, to say nothing of the rich intellectual repast. Mr. Chairman, I have felt like declaring, in imitation of Bouillaud, that Massachusetts is Boston, I had almost said that New England is Boston, and I feel inclined to commit myself to the opinion that the United States is Boston, and Boston is really the "Hub of the Universe."

Thanking you, gentlemen of the Massachusetts Medical Society, on behalf of the delegates from sister societies, for this cordial reception, permit me again to tender you our congratulations, and to express the hope, on behalf of my own Society, that you will honor us with a delegation at our

next annual meeting at Albany, on the 1st Tuesday in February.

Later still, the New York mail has brought us another acquisition—the address of Dr. Peaslee at the medical festival:—

MR. CHAIRMAN,—I trust you will pardon me if, before I speak of the medical profession of New York city, I say something respecting the city of Boston; since by so doing I am in some degree cancelling a debt of gratitude.

Born within thirty miles of this spot, it was one of my earliest aspirations, as it is at the present moment an intense pleasure, to see Boston; and just forty years ago this long-cherished wish was, for the first time, gratified. I then inspected the city as thoroughly as a boy of 15 years might be expected to do, and came to the deliberate conclusion that Boston was the largest, the most intelligent, and in every way the most desirable place in the world. Subsequent travel and a more extensive observation have since modified my early views of its relative size somewhat; but the other two propositions, Mr. Chairman, I think I am ready to defend up to the present time.

But the Boston of forty years ago was a very different city in area and architectural appearance from the Boston of to-day. You had not then become one of its citizens, Mr. Chairman; and this society could not then have held its anniversary exercises in a hall like this, and varied by music such as can be heard nowhere else on this continent, and of which accessories and surroundings, Sir, I cannot refrain from adding:—

Quorum magna pars, tu, amice fecisti.

But I turn again to the past.

I had even then heard of Drs. Warren, and Hayward, and Channing, and Jackson, and Lewis, and of him, no longer with you, whose son so honorably fills the chair of Practice in your college,\* and of him† (*et sero in calum redact*) whose son adorns the chair of Surgery in the same institution—and I decided, should I ever enter upon the study of medicine, it should be here. This plan was not, however, destined to be fulfilled. But I was destined to be under obligations to Boston in a way which I had not foreseen. My first public teacher in Anatomy was a Boston physician, and a man who better knows how to blend the agreeable with the useful in his anatomical prelections than any professor of that department to whom I have ever listened. And if I have myself succeeded as a public teacher of Anatomy, I attribute the fact in no small degree to the interest he developed in me, in that, the most important branch of our science. Need I here mention his name? The poet and philosopher, the brilliant writer, the ripe and elegant scholar—his name is a household word in all our homes.‡ My first public teacher in Theory and Practice was also a Boston physician, the scholarly and the classic Roby. The first work on Theory and Practice I ever carefully studied was also brought out in this country and in this city by two of the Boston fac-

\* Dr. Shattuck.

† Dr. Bigelow.

‡ Dr. Holmes.

ally, already named—Dr. Bigelow, Sen., and Dr. Holmes. I allude to Dr. M. Hall's Practice, published thirty years ago; a work which hardly pretends to be more than a syllabus of a course of instruction in the Practice of Medicine; but which was the first attempt in our language to base all practice logically upon Pathological Anatomy and Pathology, and has been the model upon which the more recent works on Practice have been constructed. Until I read it, the practice of our art seemed to me, as it does to too many still, to consist of a confused mass of facts, to be remembered if possible, but incapable of reference to a scientific basis—of empiricism, in fact, instead of science.

The benefit, also, which I obtained as a commencing practitioner from still another Boston influence, I should not omit to acknowledge here. I allude to the "Essay on Self-limited Diseases," by Dr. Bigelow, Sen.; which at once put an end to the vexed and vexing questions as to the jugulation of fevers; and explained all that is real in the results of homœopathic practice. I, of course, mean true homœopathic, or Hahnemann's practice; and not the practice of those so-called homœopaths who administer larger doses than any judicious regular physician does at the present day. I merely add that if the paper above-mentioned has led any to the extreme of scarcely prescribing medicine at all, this is not its fault; since it does not demonstrate that rational practice consists of expectation alone.

When I went abroad, also, as a medical student, I everywhere met the representatives of Boston. And it seemed to me that they were more moral and high-minded, and more thorough students than I met with from other quarters, and I still found it to my advantage to emulate Boston. Among them, now nearly thirty years ago, was one I have already had occasion to allude to; then a delicate looking young man, said by Baron Louis to have a tubercular deposit in his lungs, and whom, had I been then requested to give a prognosis, I should not have expected to meet here to-day; but who is now one of the most brilliant operators in this country—the Professor of Surgery in your College. May God preserve his health and strength for thirty years to come.

But if I am transgressing altogether too far it is because

"*Difficile est longum subito deponere amorem.*"

And I will now speak of the medical profession of the city of New York.

A few days since I asked one of our most eminent physicians (a native of Massachusetts) of what the medical profession of New York had reason more especially to be proud. You may, perhaps, think his reply not very complimentary to its present status. "I think," said he, "that we should be most of all proud of *what we are going to do.*" He then explained that within ten years, and perhaps within five years more, every department of medical science, and every specialty, will be as thoroughly taught in New York as in any city of the world. And we certainly have all the material for this purpose, and the required talent is already engaged in this direction.

But on taking a retrospect over the eighteen years since I first became an observer in New York, I find abundant cause of gratification at the

present condition of the profession there. It was then constantly remarked that New York was merely a commercial city, and that science and skill were neither appreciated nor encouraged there; and that the practice of our profession was regarded, by practitioners even, too much in the light of a mere trade.

There have always been many brilliant examples to disprove these assertions; and yet there was then some pretext for them in the actual status of the profession. Instead of being united upon the high ground of a common science, it was divided by cliques, and disgraced by at least one secret society, which arrogated to itself the best patronage of the city, and attempted to control it, so far as possible, by means understood for a time by its members alone. It was within this epoch that the spite of a few persons harassed and pursued a professional brother with the accusation that he had killed a patient—he being no more guilty than any one of us—and who never recovered from the effects of the sense of cruel injustice done him, of injury proceeding from such a source, but was hurried by the shock into his grave. But as an experience like that of the late Dr. Horace Green could never have occurred in Boston, as one of your eminent physicians at the time remarked, so such an experience can never again befall a worthy member of our profession in New York.

For I take pride in saying that, at the present time, medical services are as highly appreciated and as liberally compensated in New York as in any city in the world. The social position of the medical profession is also all that can be desired; and the ethical relations of physicians to each other are recognized and observed in the most precise and courteous manner. As a result of all this, the relations of physicians to their patients are, with the exceptions which the weakness of human nature must account for, all that could be wished. The respect of patients for physicians follows as a matter of course when they perceive that physicians respect each other.

Nor is it difficult to account for the improvement of the faculty of New York, in respect to the relations of physicians to each other and to society at large. It is entirely due to improved means of acquiring professional information, and the increased desire to improve which such means always develop. And not to specify too many of the medical societies in our city, I will mention the New York Pathological Society, with over 150 members, which meets once in two weeks, and is always well attended; the New York Academy of Medicine, nearly twice as large, and also meeting every alternate week; and the Medical Society of the County of New York, with nearly 300 members, and always thronged at its monthly meetings. I also should not omit the New York Medical Journal Association, with about 150 members, meeting every Friday evening, to listen, usually, to a *résumé*, from all the recent medical journals, foreign and domestic, of some practical subject.

All of these societies are open to the public, and all physicians visiting the city are invited to the meetings. And this constant meeting of the physicians of the city with each other, and drink-

ing from the same fountain, begets its legitimate results; and now the predominating influence in the profession is that of the best educated and most moral, and therefore of the wisest, the most generous and the best men in it. The era of "rings" and cliques has passed away, not to return again.

I need say nothing of the number and extent of the hospitals of New York, they are so generally known. But if we are to be more especially proud of what the profession is about to do there, I confess to no small amount of pride at what it is *now doing, and now is*.

Will you allow me, before I close, Mr. Chairman, to say a word respecting this—the Massachusetts Medical Society; for to it, too, I am indebted. While a practitioner within the territory of which this city is the metropolis, I always, if possible, attended its annual meetings. I first became acquainted thus with some of my most highly esteemed professional brethren, and not a few of them I am happy again to meet to-day. And I never attended one of its anniversaries without profit as well as pleasure. We are too prone to lose sight of the advantages of such occasions, and to ask ourselves, if far away from the place of meeting, how we can afford the time. But such occasions improve the heart as well as the intellect, and impart those fraternal emotions which isolation represses if not destroys. They enable the young practitioner, discouraged perhaps by obstacles which, up to the present, have barred his complete success, to realize that others also are struggling like himself, and reconcile him to the thought that

"Rugged places ever lie between  
Adventurous virtue's early toils  
And her triumphant throne."

And these seasons of fraternal intercourse remind the matured practitioner, borne down perhaps by an excess of labor, and sometimes inclined to escape from it to some easier avocation, that he is one of a noble brotherhood; that our profession is one to live for, or to die in; its aim, the best good of man. For

"Whether on the scaffold high,  
Or in the battle's van,  
The noblest place for man to die  
Is where he dies for man."

**MURIATE OF AMMONIA AS A REMEDY.**—Dr. Cholmeley \* \* \* \* confirms the observations of Dr. Anstie in a paper in the December number of the *Practitioner*, as to the great efficacy of the muriate of ammonia as a remedy for neuralgia and myalgic pain. But Dr. Cholmeley goes on to say that with regard to a matter on which Dr. Anstie spoke more doubtfully;—the efficacy, namely, which certain authors have ascribed to this drug as an emmenagogue—he has formed from a large experience a decided opinion in favor of the utility of this medicine. He is convinced that in a very large number of cases of absent or suppressed menstruation, muriate of ammonia acts in

a very direct and powerful manner in establishing or restoring the flux. Dr. Cholmeley has now experimented with the muriate, in doses of 10 to 20 grains, in so large a number of hospital and dispensary patients, that he cannot suppose there is any room for fallacy in this conclusion.—*Practitioner*.

Since the date [the editors of the *Practitioner* add] at which the paper referred to by Dr. Cholmeley was written, we had occasion to employ the muriate of ammonia in two cases of amenorrhœa, with apparently very striking and direct results of a curative kind. As yet, however, we must confess ourselves unable to lay down any definite rule as to the class of cases to which it is applicable with the best chance of success, beyond a general idea that it acts best in persons not anæmic, but possessing a weak and mobile nervous system.

**OVARIOTOMY.**—At a meeting of the Pathological Society of London, Mr. T. Spencer Wells reported a third series of 100 cases of ovariectomy, with remarks on tapping ovarian cysts. The author has arranged in a table all the cases in which he has completed the operation of ovariectomy, from the 200th case included in previous papers to the 300th. In other tables he gives particulars of all his incomplete and exploratory operations. He finds that the mortality lessens as experience increases. Of the first 100 cases, 31 died, and 66 recovered. Of the second 100, 28 died, and 72 recovered. But of this third series of 100 cases, only 23 died, and 77 recovered. The author has endeavored to ascertain what influence tapping ovarian cysts may have upon the mortality of subsequent ovariectomy, and he has arranged in a table all his cases where tapping had never been done, and those in which it had been done from once to sixteen times. The general mortality of the 300 cases was 28·33 per cent. Nearly one-half of the patients, or 135, had never been tapped. In them the mortality was 27·40 per cent.—not one per cent. less than the average mortality. Rather more than one-fourth of the patients, or 78, had been tapped once. In them the mortality was 25·64 per cent. There were 19 who had been tapped three times, and the mortality was 26·32 per cent. Of the 36 who were tapped twice the mortality was exactly the same as that of the group of cases tapped from four to sixteen times—namely, 33·33 per cent. The author is led by these facts, and by other considerations discussed in the paper, to the follow-

ing conclusions:—1. That one or many tappings do not considerably increase the mortality of ovariectomy. 2. That tapping may often be a useful prelude to ovariectomy, either by giving time for the general health to improve, or by lessening shock when the fluid is removed a few days or hours before removing the more solid part of an ovarian tumor; and 3. That when the syphon-trocar is used in such a manner as to prevent escape of ovarian fluid into the peritoneal cavity, and of entrance of air into the cyst, the danger of tapping is very small.—*London Medical Times and Gazette.*

DR. BERNCASTLE, in the *Australian Medical Gazette*, speaking of the venomous snakes of Australia, says:—

"I have been often asked to explain the immunity from danger certain men are supposed to have, who go about exhibiting snakes, and who are apparently bitten by them in public?

"The answer is easy, and the explanation also; these men extract the fangs with tweezers, and for a month, until they have grown again, the animal is harmless; or by teasing it with a piece of flannel, they cause it by repeated bites to exhaust the poison apparatus for a time, and its bite is deprived of danger for that day, although it might even then kill a pigeon, a kitten, or a rabbit, but not hurt a man. I have seen this done myself, and therefore can unravel the mystery. You may take for granted that there is no immunity for any living person from the effects of the poison when fairly inoculated by it, both Underwood and another of his *confrères*, Cartwright, before him, having proved that by the penalty of their lives."

ABSORPTION OF NUTRIMENT INJECTED SUBCUTANEOUSLY.—Drs. Menzel and Perco, in Vienna, seem entitled to the credit of at least some originality, and perhaps of a useful discovery; though it were premature to speak of the practical value of their researches. They began with the injection of almond, olive and cod-liver oils under the cutis of dogs—the quantity used varying from a drachm to an ounce. Finally, after twenty-five successful experiments of this kind, they obtained Prof. Billroth's consent to practise a similar injection upon one of his patients, the quantity injected in the latter case being 9 gr. [grammes?]; and with the same successful result as that obtained in the other cases, namely, ab-

sorption of the oil in from 36 to 48 hours, without any local inflammation, or any other evil consequences. Returning to their *corpora vilia*, they now injected a drachm of milk once; one or two drachms of syrupus simplex ten times; and a drachm of the yolk of a hen's egg four times, with perfect success in each case, the substances being usually absorbed completely within 24 hours.

Stricker and Oser have practised similar injections of peptone, upon patients—but the trial of undigested nutriment has not, it is claimed, been previously made.—*Wiener Med. Wochenschr.*, No. 31.

D. F. L.

THE different status of the medical profession in North Germany from that which it holds here, is strikingly shown in the efforts which are there making for the repeal of certain laws. One law imposes a penalty for refusal to attend upon an urgent case—leaving it quite uncertain in what "urgency" consists. Another forbids physicians charging more than a fixed rate; a prohibition, however, which is quite ignored by the higher class of practitioners. To appreciate the case fairly, let us imagine our Congress to have enacted a law forbidding physicians to charge more than, say \$2.00 per visit.

D. F. L.

CONSANGUINEOUS MARRIAGES.—M. Voisin states as the result of a careful examination of 1,077 of his patients at the Bicêtre and Salpêtrière, that in no one instance of his idiotic, epileptic or insane patients, could healthy consanguinity be legitimately regarded as the cause of the affection. He believes that the ill results which have been observed after consanguineous unions are not really due to these, but are to be attributed to the ordinary hereditary causes.—*Union Med.*

STEATOMATOUS TUMORS OF THE SCALP.—Dr. Kraft-Ebing says that since 1863 he has removed many of these tumors, varying in size from a bean to a pigeon's egg, by a very simple procedure. This consists in the subcutaneous injection of a few drops of a solution (0.65 in 15 parts of water) of tartar emetic. In two or three days the skin ulcerates sufficiently to discharge the contents of the tumor without inducing erysipelas or nausea. He has not in any of his cases met with return of the tumor.—*Berlin Wochenschrift*, March 15.

## Medical Miscellany.

NOTE FROM DR. SNOW, THE CITY REGISTRAR OF PROVIDENCE, R. I.—*Mr. Editor*:—In your Journal, page 351, the foot-note suggests an error in my report. The City Registrar of Boston, to get his figures, estimates the population of Philadelphia at 800,000, and of New York at 1,100,000, both of which figures are much higher than were ever claimed in those cities, and higher than the truth—very much so. If the population stated is reduced in those cities as it should be, the rate of mortality will of course be increased.

Yours truly, E. M. SNOW.

MAINE MEDICAL ASSOCIATION.—The annual meeting of the above association met in Portland recently, and continued its session two days. The attendance was quite large and the proceedings were unusually interesting. Number of members, 260. The President's address (Dr. Dana, of Portland) was an able effort. The Anatomical bill, passed at Augusta last winter, was the subject of considerable congratulation. The bill for the "Registration of Physicians and the Prevention of Quackery," which failed to pass last winter, was urgently advocated. The prevailing diseases of the year have been influenza and scarlatina. The peculiar influenza of this year was regarded as an atmospheric epidemic. A case of recovery from a club-foot, known as *Talipes varus equinus*, reported by Dr. H. S. Tewksbury, of Portland, formed an interesting discussion. Resolutions favoring the extension of term of study to four years, with three full courses, were passed. Among the other interesting subjects were Softening of the Brain and Paralysis (Dr. Harlow, of Augusta, presenting report), indiscriminate sale of drugs, Hypodermic Injections, Calculus, Necrosis of Hip Joint, Preservative Influence of Carbolic Acid, Ovariectomy, Maine General Hospital, Medical Chemistry, Progress of Medicine, Insane Hospital, Obituaries, Puerperal Convulsions, Pathological Cabinet, Portland Almshouse, Abdominal Tumors.

Dr. S. H. Tewksbury presented a lengthy paper on Medico-Legal Evidence, in which he commented severely upon verdicts in actions for railroad damages, and the treatment of physicians on the witness-stand by lawyers, and made several suggestions for their better protection.

Dr. Swasey was delegate from the Massachusetts Society.

Bangor is to be the place of meeting next year.

Some twenty new members were admitted.

Resolutions were passed complimentary to the City Government for use of rooms, Portland physicians for courtesies, and others. The following officers were elected for the ensuing year:—

President—D. McRuer, M.D., Bangor.

1st Vice President—J. M. Bates, M.D., Yarmouth.

2d Vice President—T. H. Jewett, M.D., South Berwick.

Corresponding Secretary—A. C. Hamlin, M.D., Bangor.

Recording Secretary—C. O. Hunt, M.D., Portland.

Treasurer—T. A. Foster, M.D., Portland.

LIBRARY MEDICAL DEPARTMENT UNIVERSITY OF LOUISVILLE, May 27th, 1869.—At a meeting of Delegates from [Western] Medical Colleges for the purpose of considering the question of fees, which was held this day, \* \* \* \* [the following resolutions were adopted.]

*Resolved*, That it is the hope of this Convention that a uniform scale of charges shall be adopted by all the medical colleges of our country, and we do most earnestly advise such a scale shall be agreed upon; and it is our belief that the glory and usefulness of our profession would be enhanced by the adoption of the highest rate advised by the American Medical Association.

*Resolved*, It is not less to be hoped that all the medical colleges of our country would fix a higher standard of preliminary and medical education as a pre-requisite for graduation.

*Resolved*, That the Convention request all the medical colleges in the United States to send each one delegate to a meeting to be held in Washington, on Monday, May 2d, 1870, to take efficient steps for carrying out in good faith the recommendations of the American Medical Association in reference to medical education, and also to form a permanent association of American medical teachers.

*Resolved*, That a copy of these proceedings be sent to all the medical journals in the country.

WM. K. BOWLING, *President*.

GEO. W. BAYLESS, *Secretary*.

## MEDICAL DIARY OF THE WEEK.

MONDAY, 9, A.M., Massachusetts General Hospital, Med. Clinic. 9, A.M., City Hospital, Ophthalmic Clinic.

TUESDAY, 9, A.M., City Hospital, Medical Clinic, 10, A.M., Surgical Lecture. 9 to 11, A.M., Boston Dispensary. 9-11, A.M., Massachusetts Eye and Ear Infirmary.

WEDNESDAY, 10, A.M., Massachusetts General Hospital, Surgical Visit. 11 A.M., OPERATIONS.

THURSDAY, 9 A.M., Massachusetts General Hospital, Medical Clinic. 10, A.M., Surgical Lecture.

FRIDAY, 9, A.M., City Hospital, Ophthalmic Clinic; 10, A.M., Surgical Visit; 11, A.M., OPERATIONS. 9 to 11, A.M., Boston Dispensary.

SATURDAY, 10, A.M., Massachusetts General Hospital Surgical Visit; 11, A.M., OPERATIONS.

TO CORRESPONDENTS.—The following communications have been received:—Case of Embolism—Discoloration of Crystalline Lens—Uterine Displacement—Optics, &c., as taught at the Universities.

ERRATUM.—On page 362, last issue, first line of second paragraph, for "psychological" read *physiological*.

DEATHS IN BOSTON for the week ending Saturday noon, June 19, 80. Males, 40—Females, 40.—Accident, 4—apoplexy, 1—inflammation of the bowels, 1—congestion of the brain, 2—disease of the brain, 4—inflammation of the brain, 2—bronchitis, 1—cancerum oris, 1—consumption, 13—convulsions, 1—debility, 1—dropsy of the brain, 2—epilepsy, 1—scarlet fever, 9—typhoid fever, 2—glanders, 1—disease of the heart, 3—homicide, 1—infantile disease, 2—intemperance, 1—disease of the kidneys, 3—inflammation of the lungs, 6—marasmus, 1—old age, 1—paralysis, 2—puerperal disease, 1—purpura, 1—pyæmia, 1—scrofula, 1—suicide, 1—teething, 2—unknown, 6—whooping cough, 1.

Under 5 years of age, 34—between 5 and 20 years, 8—between 20 and 40 years, 16—between 40 and 60 years, 18—above 60 years, 4. Born in the United States, 50—Ireland, 18—other places, 12.

# Original Communications.

## RECOVERY FROM PNEUMOTHORAX, OCCURRING IN A CASE OF INCIPIENT PHTHISIS, WITHOUT PLEURITIC EFFUSION.

Read before the Boston Society for Medical Observation  
by F. L. Knight, M.D.

Miss L. R., a lady's maid, 23 years of age, has always been delicate. Her father is said to have died after three days' sickness, "with a stitch in his side," at the age of 63. Her mother is well at the age of 60. She never had any lung trouble. They had three children; one died in infancy, one daughter is well.

Miss R. never had any long sickness. In January, 1868, she caught cold at a party; had a cough from that time until the next summer, and failed in strength. She thinks she had no cough in the fall, but sometimes had a little tightness at the top of the right chest. In September, 1868, she applied to a physician, who told her there was no disease of the lung, but gave her medicine, which caused her to spit up much thick, offensive matter, and relieved her. She never had hæmoptysis. She says she felt quite well in the beginning of the last winter, but that she got easily fatigued. She insists that she had no regular cough, but sometimes felt a kind of wheezing at the top of the right chest.

On the evening of February 8th, while walking in the street, she felt a stitch across her shoulders, and then a choking sensation and shortness of breath. She, with the aid of a companion, was able to walk home. I saw her for the first time on the afternoon of Feb. 9th. She was lying on her back, with her head raised; her face was slightly flushed; there was nothing like lividity; her countenance was somewhat anxious. When she was lying quiet the respiration was somewhat accelerated, but there was no urgent dyspnoea. The circulation was only very moderately accelerated, the pulse beating about 90 per minute. She had no cough or expectoration. Her voice was

somewhat weakened. She only complained of tightness about the upper part of the sternum. Physical examination:—

On percussion there was much more resonance throughout the right chest, front and back, than in corresponding parts of the left.

On auscultation there was amphoric respiration, with amphoric whisper, and metallic tinkling synchronous with the respiration, heard over nearly the whole of the right chest.

The exaggerated resonance on percussion extended to the very base of the right chest, and there was no sound produced within the chest by succussion.

The above signs could only indicate pneumothorax. The absence of any dullness at the base, and of succussion sounds, showed that there had been no pleural effusion.

Other symptoms and signs in this case, unnecessary for the diagnosis, but which might have been interesting, were not recorded at the bedside, and hence cannot properly, according to the rules of the Society, be reported here.

Having ascertained the existence of pneumothorax, we will next, if possible, find out its cause. The various causes which may lead to the presence of air in the pleural cavity, are classified by Walsh under four heads:—

*I. No Communication Existing between Pleura and External Air.*—(1) Gangrene of pleura; (2) Chemical decomposition of pleural fluid; (3) Air replacing sero-purulent fluid, suddenly absorbed; (4) Secretion by pleura.

*II. Communication between Pleura and Alimentary Canal.*—(5) Rupture of œsophagus into pleura.

*III. Communication with Atmosphere through Opening in Chest-wall.*—(6) Penetrating wounds of thorax.

*IV. Communication between Pleural Sac and Bronchi.*

*a. Traumatic.*—(7) Tearing of lung-surface by broken ribs. (8) Violent contusion of chest, tearing lung without costal fracture.

*b. Perforation, from Disease opening the Pulmonary Pleura from within outwards, or*

*centrifugal.* (9) Tubercle; (10) Gangrene; (11) Diffuse pulmonary apoplexy; (12) Hydatids; (13) Cancer; (14) Emphysema; (15) Abscess; (16) Rupture in pertussis; (17) Excavated bronchial glands opening into the pleura and bronchi.

*c. Perforation from Disease opening the Pulmonary Pleura from without inwards, or Centripetal.*—(18) Empyema; (19) Parietal abscess.

We are enabled to exclude the First Class from consideration (that including the cases where no communication exists between pleura and external air), because we have evidence of such communication in the amphoric respiration heard over the right chest.

Class Second, in which there is a communication between pleura and alimentary canal, we exclude, because there are no symptoms of rupture of the œsophagus, or of previous disease, which might lead to its rupture.

Class Third is excluded, because there had been no penetrating wound of the chest.

We have now only the Fourth Class left, and of this, subdivision a. is excluded, because the patient had sustained no injury to the chest; subdivision c. is excluded, because the patient had no sign of empyema, or parietal abscess, which would cause perforation from without inwards. In subdivision b. we find (9) Tubercle, which is the cause of pulmonary perforation in the great majority of cases of this affection. Have we any evidence that our patient had so-called tubercular disease of the lung? We have no proof of it. Absolute proof of disease of the lung can only come from physical examination. I had not examined her before the development of pneumothorax, and we cannot judge accurately of the condition of the lung itself when it is surrounded by air. But she had symptoms of phthisis; she had continued cough for the first six months of last year, and lost flesh; for the rest of the year, though she says she had no regular cough, she sometimes had a little, and a tightness at the top of the right chest.

To the fact that she was told by a physician who examined her in September, that she had no disease of the lung, I do not give much weight, for the examination may not have been a careful one, and we cannot depend upon the statements of patients in regard to physicians' opinions. Although she says that she had no regular cough after summer, I suspect she had, for she had her lungs examined for some reason in September, and took cod liver oil later, I believe.

If phthisis was not the cause of the perforation, what could have been? In subdivision b. we find, besides phthisis, gangrene, diffuse pulmonary apoplexy, hydatids, cancer, emphysema, abscess, rupture in pertussis, and excavated bronchial glands opening into the pleura and bronchi, none of which we have good reason to suspect of being the cause of the perforation in this case, excepting possibly vesicular emphysema.

Gangrene and abscess require perhaps a passing notice, as she says she, after taking medicine, "spit up much thick, offensive matter." I could not elicit that the sputa had the peculiar offensiveness of gangrene, or was in such quantity as would imply the emptying of an abscess.

As she never had the symptoms of the diseases which usually precede gangrene or abscess, I think we may exclude them as a possible cause of the perforation in this case, particularly as the offensiveness and excessive amount of sputa had been long absent.

So, now, the question must be between tubercle and vesicular emphysema. I considered tubercular disease to be the cause of the perforation for the following reasons:—

1. Tubercle is a far more common cause of such perforation than is vesicular emphysema.

2. Vesicular emphysema is very rare in a person of her age, especially one with no hereditary tendencies to it.

3. Vesicular emphysema, though often more marked in one lung, or one lobe of one lung than the other, yet is a bilateral affection, showing itself to some degree on both sides.

There was no evidence of vesicular emphysema of the left lung.

4. She had *symptoms*, before the perforation, of tubercle rather than of emphysema. A cough so slight much of the time as not to attract notice, and the absence of dyspnoea, or anything like asthma, are in marked contrast to the harassing cough, and oftentimes great distress of breathing, common in emphysema.

I wish it to be understood here that I do not deny that there may have been rupture of an emphysematous vesicle, such as is found about a tuberculous deposit, but only that I consider the disease of the lung, which caused cough, &c., a year ago, and which was the ultimate cause of the perforation, to be phthisis and not emphysema.

Considering it probable that the perforation is due to "tubercular" disease, we will next consider the subject of *prognosis*.

We are generally told that the perforation of lung in a case of phthisis is very soon followed by pleurisy with effusion, the case thus becoming one of pneumo-hydrothorax. Considering it probable, then, that this case is soon to become one of pneumo-hydrothorax, what will the prognosis be? The prognosis in this affection is said to be always bad; but it is not equally so in all cases.

The points to be considered are well brought out by Dr. R. Douglas Powell, in the *Medical Times and Gazette*, Feb. 13th, 1869. He writes essentially as follows:—

"The intensity of symptoms in pneumothorax is influenced by—

A. The condition of the lung previous to its rupture.

(1.) The greater or less amount of respiratory area suddenly cut off.

(2.) The increased resistance to the flow of blood through the capillaries of the affected lung.

The greater the amount of healthy tissue left by disease, and hence suddenly collapsed, the greater the disturbance of the equilibrium, if one may use the term, between the aerating power and the blood-volume to be aerated, and hence the more urgent the dyspnoea."

"Although it was proved by Goodwyn, and more lately by Mr. Erichsen, that mere collapse of the lung does not materially affect the circulation through it, and although Mr. Erichsen's experiments tend to show that the cessation of the vital changes of respiration does not retard the circulation through the lung, yet in many cases of pneumothorax the lung is subjected to considerable pressure, and is more completely collapsed than in any of the experiments."

From some of his own experiments, he infers that "there is no appreciable difference in the resistance to the circulation through a moderately expanded lung and one collapsed by its own elasticity."

"When the lung is more completely collapsed there is a decided increase in the resistance to the circulation through it."

"The complete collapse of the lung has a very marked effect in retarding the circulation through it, independently of all external pressure."

"In this way the normal quantitative relation between the two circulations is interfered with, and death would result, but that the systemic veins admit of some, and the portal system of still greater engorgement, by which a certain amount of the surplus blood is temporarily removed from

the general circulation, and time is allowed for more permanent relief, either naturally or by treatment."

"B. The state of the other lung will obviously affect the symptoms, which will be intense and fatal, *ceteris paribus*, in direct proportion to its disease."

"The nature of the opening will affect the symptoms, which will be the more urgent in proportion as the opening is more or less completely valvular."

"The temperament of the patient will influence the amount of shock."

Returning now to our patient, we are warranted in the belief that the amount of disease in the right lung previous to its rupture was slight, and that a large respiratory area was suddenly cut off.

On the other hand, the patient had in her favor the fact that the left lung was free from disease, and fortunately the opening in the pleura was perfectly free, as shown by the constant amphoric respiration.

If I had seen her at the time of the perforation, considering that she had been suddenly deprived of the use of so much lung, I should have predicted intense symptoms; but seeing her twenty-four hours after the accident so comfortable as I have described, with a non-valvular opening, I felt that no urgent symptoms need be expected until after considerable effusion, which I naturally looked for.

The condition, progress, duration, and probable termination I put thus in my own mind. She has suffered a serious accident, and has borne the shock of it much better than could have been expected. She will in all probability recover from the immediate effects of the accident, but liquid will be effused, and air and liquid will remain in the chest for an indefinite time, causing dyspnoea on exertion. It is possible for the opening to close and the air to disappear, or the air and liquid, if it should happen after effusion has taken place; but it is not probable. Finally, disease will probably attack the left lung, and thus the patient will ultimately succumb.

For treatment much less was necessary in this patient than is often required. She took quinine, beef-tea, a little wine and an occasional cathartic, and after a few days whatever food she desired.

If I had not made up my mind that there was almost no chance for the opening in the pleura to become closed, I should have in the beginning applied adhesive plaster to the affected side to prevent motion as far as possible.

*Progress of the Case.*—I saw the pa-

tient at first every-day, and afterwards at intervals of a few days for two or three weeks. In a few days she suffered none from dyspnoea, and was able to be about the house. She complained only of weakness. She had no cough. She then moved to a distant locality. I had never found any signs of pleural effusion. The last time I saw her before her removal, the amphoric respiration was less distinct, but still evident.

April 1st.—I visited her. She experienced a very little dyspnoea on exertion, but occasionally had a feeling of tightness across the top of the chest. She had no cough in the morning; occasionally a little in the afternoon. She complained a good deal of weakness.

On examination of the chest, I found percussion normal. Respiration vesicular throughout both lungs; somewhat less intense at lower part of right lung. Vocal signs normal. On cough, very numerous fine, moist râles were heard from the right clavicle to the third rib on that side.

The perforation had evidently been closed and the air absorbed from the pleural sac, but there was evidence of phthisis at the right apex. As there is slight dullness on percussion, more bronchial element in the respiratory murmur, and more resonance of the voice in health at the right apex, compared with the left, in making a diagnosis of incipient phthisis in this region we are obliged to depend upon the signs of secondary bronchitis, viz., the moist râles, and as these were heard over a circumscribed space at the summit of the chest, we are justified, considering the symptoms previous to the perforation, in inferring the existence of phthisis.

I ordered her to lead an indolent life, to devote herself principally to eating, drinking and sleeping, to keep in the open air as much as possible, to take such exercise only as she could take without much fatigue, and to take, an hour after breakfast and an hour after tea, 3i. cod-liver oil with whiskey.

I saw her on the 28th of April. She was then able to walk a mile without rest and without subsequent fatigue. She had no cough, but a little dyspnoea on going up stairs. She complained still of weakness and of loss of appetite. The physical signs remained as at last report. I ordered her to resume the quinine, which had been suspended several weeks before, and to continue the cod-liver oil and whiskey.

The case is interesting, because—

1. Perforation of the pleura in a case of

phthisis was not followed by pleural effusion. I do not remember having seen any record of such a case.

Can we find any reason why effusion did not occur?

Effusion in these cases is considered by many to be dependent on the irritation of the pleura by liquefied tubercle rather than on the irritation of the air. Now this case was incipient and rather latent, and had not probably advanced to softening, so the pleura was not liable to irritation from this source. This seems to me the most probable reason why effusion did not occur.

2. Perforation of the pleura in a case of phthisis became closed, and the signs of pneumothorax disappeared in less than two months after the accident.

This was probably due to the fact that effusion did not occur.

3. The symptoms immediately after the perforation were quite light, when we should have expected them to have been intense, as the patient was suddenly deprived of a large respiratory area. If there had been reason to suppose very extensive disease of the right lung previous to the pleural rupture, then we should not have expected the sudden admission of air to the pleural sac to have been followed by urgent symptoms, because the system would have been previously deprived of the use of much of the lung-tissue. But in this case there was every reason to suppose that the disease was not extensive.

The key to a proper prognosis in regard to the urgency of symptoms, or the progress and termination, in cases of pneumothorax, has not yet been found, but I consider in this case that the lightness of symptoms was due, in a great measure at least, to the existence of a very free communication between the pleural sac and bronchi, so that there was mere collapse and not compression of the lung.

In this case (i. e. collapse without compression), according to the experiments of Goodwyn, Erichsen, and Powell, there would be no interference with the circulation, to which in cases of pneumothorax much of the intensity of symptoms is probably due.

4. It proves that much liquid is not necessary for the production of the physical sign known as metallic tinkling.

There was probably a little bubbling of mucus about the perforation, but not the slightest evidence of any liquid at the bottom of the pleural sac.

The treatment of this case was fortunately very simple, but as it should not

always be so, it may be well to run over here the general line of treatment which it may be proper to pursue.

1. Prevent motion in the affected side by adhesive plaster.

2. Relieve shock by opium, especially subcutaneous injections, and alcoholic stimulants. Without these we may have fatal syncope. But if the patient is strong, and seen early, bleeding may be properly resorted to. Walsh says:—"The quantity of oxygenating surface has been suddenly reduced, and the sudden disparity between that surface and the mass of the blood might, or must, I think, be somewhat lessened by diminishing the quantity of the latter. Whether this be the explanation or not, venesection does give very notable relief, and renders subsequent inflammation of the pleura less violent." Cupping, dry cupping, blisters, cannabis Indica, belladonna, stramonium, aconite and musk have also proved useful in relieving dyspnoea.

3. When there is much interference with the circulation, give hydragogue cathartics to relieve the venous congestion, and if the non-affected lung is encroached upon, and there is danger of asphyxia, puncture the chest and relieve the compression of lung.

4. Sustain the patient by a nutritious diet.

## Reports of Medical Societies.

OBSTETRICAL SOCIETY OF BOSTON. SECRETARY,  
DAVID F. LINCOLN, M.D.

APRIL 10th, 1869.—The Society met at the house of Dr. Putnam, at 7½, P.M., the President, Dr. Buckingham, in the chair.

Dr. COTTING reported the following case.

Mrs. — had a good labor, her first. The milk was secreted well. On the 11th day the nurse gave—for what she thought insufficient lochial discharge, though normal in quantity—a hot injection of fennel-seed tea. The patient immediately uttered a shriek; a terrific rigor followed; and then convulsive vomiting, pains in the limbs, lasting all day, excessive rapidity and feebleness of pulse, tympanites and tenderness of the abdomen. Three dejections, with much pain. The lochial discharge remained slight. The next day, she was better; recovery speedy. "What did the injection do?"

Dr. BUCKINGHAM reported the case of a young woman, confined with her first child six weeks ago. The subsequent flow was

slight, but very offensive. About four weeks after labor she was making very slow improvement; and as the offensive discharge was considered to be in part the cause of her unfavorable state, an injection was ordered—of blood-warm water, with a little salt—per vaginam. Its administration was immediately followed by a violent pain in the uterus, extending over the whole abdomen. A drachm of McMunn's elixir was given, and in three hours she fell asleep. Next day she was as well as ever, and the discharge had ceased. Two days ago he tried to give an enema to the baby, to relieve constipation. He found he could not fill the syringe; and unscrewing the instrument, discovered that one valve was gone. The nurse remarked "that it was *very hard to fill the baby*" with that syringe. It was a new instrument, and was the same which had been used for the vaginal injection of the mother. Probably air instead of water had been pumped in considerable quantity into the mother's vagina, and very likely into the uterus.

Dr. COTTING said that the instrument used in his case was a good one, and the injection of air quite improbable. He did not, however, see what greater harm would be produced by air alone than by the fluid, if injected as described.

Dr. SINCLAIR mentioned a case where by direction he injected with a flexible catheter a solution of tannin for menorrhagia, into a uterus which had elongated to seven inches over a mural fibrous tumor. Pain resembling that of labor instantly ensued, extending to back, abdomen and thighs. Has never since injected the uterus in similar circumstances, though he apprehends no trouble if before injection the cavity were sufficiently dilated. He stated further that air injected with a rectal enema often caused much pain; to avoid which, he cautions that the air be expelled from the syringe by completely filling it before inserting the nozzle into the rectum.

*Death of the Fetus shortly before labor, in a household attacked with well-marked Measles; the Mother remaining strong and well.*  
—Dr. RAYMOND reported the case.

Q. L., aged 34, a healthy woman, in fine bodily condition, was approaching the close of her fifth pregnancy. Three and a half weeks before labor a child seven years old had well-marked measles. Two weeks later the oldest, nine years, was attacked with the same disease. One week before delivery the fetal movements, which had been for some days losing force, wholly ceased. The child, a large, well-developed male, was

born on the evening of the fifth instant. The mobility of the bones of the head, the condition of the epidermis, the color of the serotum, eyelids and softer parts, and the purple and softened state of the cord, showed that death had taken place several days before birth. The placenta was throughout in a condition of fatty degeneration.

He asked whether there is, in this case, any reason to connect the death of the child with measles; whether strict care requires the removal of a child-bearing woman from the presence of an eruptive disease, even though the house should be, as in this instance, newly-roomed, well-aired and sunny.

Dr. HOOKER would advise separation, if the family lived in close quarters.

Dr. PUTNAM would regard the issue with solicitude.

Dr. SINCLAIR, in connection with the subject of fetal auscultation, spoke of a case which came under his care while resident surgeon at the Royal Maternity Hospital, Edinburgh. A woman representing herself to be seven months advanced in pregnancy, imagined her child to have died in utero, the usual fetal motions having been absent for two weeks. Beside himself, two experienced obstetric auscultators made several unsuccessful attempts to discover the fetal pulsations. Two months later, however, she returned to the hospital and was delivered of a fine living child.

Dr. REYNOLDS quoted a statement by Cazaux, that in an experience of many years, he had in no instance failed to hear the fetal heart, when as late as the sixth month repeated examinations had been made, unless in cases where the child was subsequently shown to be dead.

Dr. BUCKINGHAM mentioned the case of a woman, near her confinement, in whom he heard a loud, distinct fetal cardiac sound above one groin. Two students who examined her with him on different days, were unable to hear it. By another physician it was plainly heard, but on the other side, and with a difference of 15 pulsations per minute. A week later, the woman was delivered of twins.

Dr. REYNOLDS made the following remarks:—

In agreement with the teaching of Uvedale West, he believed the existence or non-existence of due flexion of the head to be the vital point in regard to cranial mal-position, not the question whether the posterior fontanelle look a little more or a little less backward. If in any case both fontanelles are within easy reach, the occipital end of the head is certainly coming

down, and the position is good enough, provided no disproportion exist. Under these circumstances the occipital end of the head will come to the arch in due time, whether the turn required be three quarters of a half pelvis or only one quarter. If, on the contrary, the posterior fontanelle can only be reached with difficulty or not at all, if the great fontanelle be central, and the frontal suture be easily made out in considerable extent, the mal-position is not to be disregarded; such a case terminating in the great number of instances with the frontal end of the head at the arch, and that whether the posterior fontanelle be thought earlier in the labor to be placed obliquely forward or obliquely backward. More than this, in cases where the head is still high in the pelvis, a seeming backward direction of the posterior fontanelle is often only apparent, not real, and will disappear, or seem to come forward, if the woman be made to lie on her other side, and be then examined with the other hand of the accoucheur. (See "Cranial Position," by R. Uvedale West, in the *Glasgow Medical Journal*, parts xv. and xvi., 1856, 1857.)

*Mode of applying the Forceps.*—Dr. REYNOLDS thinks that in this neighborhood the usual practice is to apply the blades on the sides of the pelvis, without reference to the cranial position. All things considered, this manner of application seems to him to involve the least risk, and for inexperienced operators to be at once much easier and far safer. It is well known that not unfrequently, in oblique positions of the head, the desired rotation takes place within the blades of the forceps during extraction.

Dr. AYER mentioned a case of labor, in which he was obliged to use traction by means of the long forceps during forty minutes. The mark of the instrument, a decided bruised dent, was visible on the upper and central part of the forehead, and over the left ear. In natural presentations he thinks it safe to apply the forceps where most room is found, trusting to them to find the best position, provided we can lock them.

Dr. ARNSOLD reported the birth of a child weighing 15½ pounds; labor lasting only an hour.

Dr. WELLINGTON reported a similar case, attended with rupture of the perineum into the sphincter ani. Ordinary stitches were put in, and removed in four days, the wound doing well.

Dr. LYMAN thought that very little was gained by sutures, beyond keeping the parts from sliding over each other.

Dr. ARNOLD said that in several cases of rupture he had never used sutures and never seen unfavorable results.

Dr. LYMAN mentioned a case that had been left without suture and had failed of union.

Dr. HOOKER never used stitches but once. That case was, at least, a partial success. He never had a case of rupture followed by loss of power of the rectum or bladder, or prolapse of the vagina, or vesico-vaginal fistula.

## Bibliographical Notices.

*The Surgical Treatment of the Diseases of Infancy and Childhood.* By T. HOLMES, M.A., Cantab., late Surgeon to the Hospital for Sick Children, &c. &c. Second Edition. Philadelphia: Lindsay & Blakiston. 1869. Pp. 687.

THE present issue of the above-named volume has been improved by the addition of several chapters and variously modified in accordance with the suggestions of reviewers and the reflections of the author himself. It now forms a comprehensive treatise upon a large class of affections, frequently occurring in early life, which are discussed with great erudition and in a style strongly contrasted with much that is offered in a more pretentious manner. Composed in a spirit thoroughly imbued with the importance of pathological ideas, questions of mechanical treatment and operative interference are entirely subordinated to those which involve the diagnosis and anatomy of morbid lesions; and though, from the habit and drift of the author's literary career, the various chapters are somewhat in the nature of reviews or arguments, based upon what has been said and written in different languages, they are in no sense mere compilations, but fully deserve to stand as representative of English surgery at the present day.

"Congenital affections," which take up one third of the entire volume, naturally constitute an important part of the surgery of childhood, and it would be difficult to direct the reader to a complete account, elsewhere than in this book, of many subjects included under this head, the actual status of which could otherwise be learned only by searching through medical journals, hospital reports and transactions of societies.

The complicated subject of Spina Bifida

and Congenital Sacral Tumors is treated with much elaboration, and though the confusion which prevails in regard to these deformities is by no means unravelled, a large number of valuable cases and facts have been brought together. Mr. Holmes speaks of "the whole spinal cord or the corda equina passing through the opening" of a spina bifida (p. 79). It is an observation of Cruveilhier's that when spina bifida exists below where the cauda equina usually begins, viz., at about the second lumbar vertebra, the cord continues down in substance into the sac. This statement has been invariably confirmed in this city, and for more than twenty years commented on in his lectures by Dr. J. B. S. Jackson. It finds its explanation in the fact that the malformation has commenced at that period of embryonic life when the cord extends to the very extremity of the vertebral canal, as it normally does at a certain stage of its primitive formation.

We should be glad to have seen some reference made to an important division of this malformation into two varieties, viz., those in which the tumor is formed by fluid collected in the space between the dura mater and spinal cord (meningocele), and those in which it is formed by fluid contained in and distending the central canal of the cord itself (myelocoele). In the first named variety the membranes are alone concerned; in the second the marrow itself is involved, becomes gradually distended and atrophied, until there is an actual interruption in its continuity. It is true Cruveilhier asserts that he has never seen any evidence of the fluid being contained in the substance of the spinal cord, but Virchow, in later observations, has shown the progressive steps of its distention, and in one case of spina bifida, the tumor being as large as a hen's egg, he distinctly saw the point of communication between the cyst and the cavity of the central canal (Tumors, t. i., p. 182). The distinction between a meningocele and a myelocoele is therefore by no means unimportant, for in the former a favorable result may follow the evacuation of the liquid, whereas in the latter the operation can scarcely fail to be attended by grave cerebral disturbance. Mr. Holmes gives an instance in which spontaneous rupture was followed by recovery (p. 83), but he does not speak of the possibility of its occurrence during intra-uterine life, the child, in rare instances, being born cured, with a puckered cicatrix, or with a red, excoriated and weeping stump, so to speak, resembling in ap-

pearance the tumors (*cerebra spuria*) seen outside the heads of anencephalous fetuses, and which are the remains of hydrocephalic brains similarly ruptured before birth. It will be noticed that the two forms of *spina bifida* correspond to the two forms of hydrocephalus, in which the fluid is either external or internal to the ventricular cavities.

Aside from any question of treatment, there is a great difference in the symptoms presented by these two varieties of *spina bifida*. Myelocoele, which is found in the dorsal or cervical region alone, is almost inevitably accompanied by an incurable paralysis, while a meningocele may remain during a lifetime as a local lesion of comparatively little consequence. This is especially true when the tumor is covered by integument and other soft parts, and especially if developed in the region of the sacrum. The innocuity of the affection at this point long since attracted attention, and many instances have been reported in which the subjects of such a malformation reached adult life with few if any concomitant symptoms. (See a paper by Dr. J. B. S. Jackson, on "A Peculiar Form of *Spina Bifida*," in *Records of Boston Society for Medical Improvement*, vol. iii. p. 175; also Morgagni, Virchow, Lebert.)

The singular instance of malformation occurring in the practice of the late Dr. Huntington, of Lowell, described as "a *spina bifida* in the form of a pendulous tumor, successfully removed," is quoted from this *Journal* of July 3d, 1862, but the record is thought to be so unintelligible as to justify a doubt whether it really was a case of *spina bifida* (p. 78). This criticism is certainly deserved; but having been induced by it to examine the preparation, which is in the Museum of the Massachusetts Medical College, we think there can be but little hesitation in pronouncing it an example of the affection in question. When presented to the College it had been in spirit three or four months, and its remarkable pedicle, alleged to have been a foot in length before the removal of the tumor, had then shrunk to the much smaller dimensions, recorded by Dr. Jackson, of two inches and a half. The deficiency in the bones of the spine at the point where the pedicle was attached, which unfortunately is not definitely stated; the characteristic absence of integument upon the tumor, and the bulging of the cicatrix left by the excision of the growth, whenever the child cried, would convince anyone who saw the specimen that it could be nothing but a *spina bifida*. The

tumor itself consists of a single large and smoothly lined cavity, and though there are in the thickness of its parietes a few small cysts, as is not uncommon in *spina bifida* (Jackson, Virchow), they alone, and not the tumor, are entitled to the name of "polycystic," which Mr. Holmes applies to it. The case deserves to be relieved from the discredit it has incurred, on account of its very exceptional if not unique features. It probably belongs to that form of *spina bifida*, in which the neck of the sac becomes obliterated, and the latter detached from the spinal membranes, a class which is alluded to at p. 90, and the existence of which Virchow admits in his lecture on this description of tumors. The recovery of the patient after the operation of removal corroborates this view.

"Congenital sacral tumors," caused by a hernia of the spinal membranes through a deficiency in the vertebral column, or through natural orifices, and those due to fetal inclusion, are comparatively well understood, but the "congenital cystic tumors of the sacro-coccygeal region," belonging to neither of these categories, and of which a number have been observed and safely removed by operation, are still obscure in their origin and pathology. Various spoken of as "arachnoid cysts of the sacral region," "coccygeal tumors," "sacral hygromata," "false *spina bifida*," they constitute a distinct class of congenital tumors, of an extremely complex character. Ranging from simple cysts to fibroids, through all the varieties of cystic modification, and not to be confounded with fatty tumors, or the caudal excrescences of a lipomatous nature occasionally observed, they possess one feature in common, viz. :—that in whatever locality the principal portion of the growth may lie, whether within the pelvis, in the perinæum, scrotum, gluteal region or the thigh [some indeed being said to have extended down as far as the popliteal space, and even to the heel]—a more or less defined pedicle connects the tumor with the coccyx or the front of the sacrum, these bones being perfectly developed, and no communication with the meninges of the spinal cord being traceable. Since the discovery of the *coccygeal gland* the histological structure of some of these tumors, and their constant point of origin, have led to the supposition that they might be pathological modifications of this newly found body.

The coccygeal gland was discovered in 1859 by Luschka, Professor of Anatomy at Tübingen. It is situated at the anterior part of the lower extremity of the coccyx,

in the median line, between the levatores ani muscles, and lies in close relation with the ganglion impar of the great sympathetic nerve. It is of about the size of a hemp-seed, of a pale red color, and consists either of a single round mass, or of several aggregated granulations. The microscope shows it to be composed of glandular tissue, principally made up of round or polygonal cells, distinctly nucleated, and surrounded by exceedingly delicate granular matter, easily destroyed. It is permeated by numerous irregular tubules and culs de sac, of vascular origin, derived from a small nutrient vessel constantly found entering the gland from the sacra media artery; indeed, the disposition of vessels and their number is such that the whole structure might erroneously be considered as of vascular formation. It receives many nervous filaments from the terminal branches of the ganglion of the sympathetic. (See *Journal d'Anatomie et de Physiologie*, 1868, p. 269.)

The elementary structure of this gland has been detected in some of these congenital cystic tumors, and W. Braune (the title of whose brochure, *Die Doppelbildungen und ausserbornen Geschwülste der Kreuzbeinregion*, Leipzig, 1862, largely quoted from by Mr. Holmes, is omitted in the foot-notes), as well as MM. Perrin and Molk of Strasbourg, admit unhesitatingly a belief in their development from it. So few observations have, however, been made since this relationship was suspected, that the question is still an open one, and must remain so until the gland has been more carefully studied in the fetus, and its alterations at the commencement of these cystic formations further examined.

There is, however, another aspect from which this inquiry gains additional interest. It is well known that the neck is a frequent seat of congenital cysts. There is in this region a little body, found near the bifurcation of the carotid artery, heretofore described as the *middle cervical ganglion* of the great sympathetic. Recent observations have given this a new character, and both Luschka and Arnold consider it a gland and not a nervous ganglion. Formed of tubules, supposed to be of vascular origin, each tube being lined with an epithelial layer and containing nucleated cells, free nuclei and granular matter, as well as many nerves and nerve cells, it presents a structure identical with that of the coecygeal gland, and is now called the *glandula intercarotica*, or *gland of Luschka*. Kölliker, in his last edition (1867) accepts these views, and they have been since confirmed by Plöörner.

VOL. III.—No. 22A

From this gland the compound congenital cysts of the neck are supposed to originate, and the suggestion finds confirmation in the clinical facts, well known to any one who has been unfortunate enough to meddle with them, that they are excessively vascular and of very deep origin. Further observation, especially as regards the period of intra-uterine life at which these cysts form, is desirable to confirm this etiology. They have been found as early as the fourth month. (See *Gazette Hebdomadaire*, April 16, 1869, p. 264, and Boucher, *Etude sur les Kystes Congenitaux du Cou*, Paris, 1868.)

It is singular that Mr. Holmes makes no mention of these curious items in the pathological history of perineal and cervical cysts, recent discussions having made them prominent, though they may eventually prove of no importance. This is the more noticeable since, in the interval between his two editions, a comprehensive article upon these tumors has been written by Simon Duplay, in which Mr. Holmes's observations on the subject are so favorably alluded to, that the paper could scarcely have escaped his notice. It may also be observed that no description is given of those congenital dermoid cysts of the floor of the mouth, which contain sebaceous matter, churned by the action of the muscles into innumerable balls, varying in size from the head of a pin to that of a marble, according as the cyst is large or small. A very considerable number of these have been operated upon in this city, and five cases were reported by Dr. H. J. Bigelow, so long ago as 1858. They are also described by Denonvilliers in the *Compendium de Chirurgie*, and by M. Paquet in the *Archives Générales*.

A peculiar case of encephalocele is cited in a foot-note to p. 63, from the Transactions of the London Pathological Society, in which a tumor protruding from the mouth was found after death to be produced by a bulging of the membranes of the brain through an orifice in the base of the skull, near the sella turcica, and to be formed of gray cerebral substance, seemingly a new growth, but not constituting an integral part of the brain. A counterpart to this may be found in the Museum of the Massachusetts Medical College, in which a perforation of the body of the sphenoid is accompanied by a tumor, which we have the authority of Dr. Jeffries Wyman for saying is the pituitary body. A similar instance, with a striking illustrative wood cut, may be found in Virchow's lectures on tumors.

Under the head of congenital malforma-

tions in the neck, closure of the œsophagus is spoken of as occurring "pretty often;" but of occlusion, with inter-communication between the œsophagus and trachea, only three cases are given. Of this malformation there are two specimens in our College Museum, and the Catalogue contains a reference to two others, observed in the practice of the late Dr. R. D. Mussey when he resided in Salem. To these we may add those of M. Tarnier, who, in a paper read before the Academy of Medicine in 1866, narrates a case of his own, and collects twelve other instances of occluded œsophagus. (*Archives Gen. de Méd.*, 1866, p. 238.)

In speaking of imperforate anus Mr. Holmes does not seem to consider a communication between the gut and the urethra in the male, or the vagina in the female, as of frequent occurrence. According to Dr. Jackson, except in monsters, and in one case where the entire large intestine was wanting, it has existed in every specimen he has examined. Several adult female subjects with this deformity have also been known to physicians in this neighborhood. The disastrous trocar punctures, not unfamiliar to surgeons here, are made the text for a condemnation of that instrument in cases of imperforation, and for the advocacy of the exploratory incision. This proving unsuccessful, or seeming unlikely to reach the intestine, Mr. Holmes advises opening the colon in front by what is known as Littré's method. "The paradox of M. Huguier," that the sigmoid flexure is to be looked for in the right iliac fossa, and not in the left, is elaborately discussed, and the conclusion arrived at, that it is immaterial in which groin the opening is made, as the colon may be reached about equally well from either direction. The chapter on imperforate anus and rectum we think is one of the most admirable in the book.

There are many points to which we should like to refer, connected with the subjects of hare lip and cleft palate, and the better success of operations which has been made possible in the latter deformity by the use of Mr. Smith's "gag," and the consequent facility of their performance under ether; with that of extrophy of the bladder and the means available for its relief; two successful operations having been recently performed by Dr. Bigelow at the Massachusetts General Hospital; and with that of malformations of the genital organs, especially phymosis. This, though mentioned as of frequent occurrence, is not stated to be of constant and uniform existence in

new-born children; another point of anatomy which we owe to Dr. Jackson's accurate observation, who has also shown that in the fetus adhesion of the prepuce to the glans penis is invariably found. A gallant soldier, killed in the late rebellion, bore throughout his life the traces of an ineffectual attempt on the part of an eminent surgeon to rid him soon after his birth of this supposed defect.

Space hardly remains for comment on the other two divisions of the book before us, which treat of "Injuries" and "Diseases." We are happy to express our accord with the author, and respect his independence when he says:—"I am afraid that in some quarters I shall be accused of being much behind the age if I confess that I am in favor, as far as present experience goes, of the old method of tying the vessels, over the new one of securing them with needles. I have never seen any harm whatever from the use of silk ligatures in childhood, nor, in the experience I have had, any good whatever from the use of acupressure" (p. 229).

We also desire to cite Mr. Holmes as saying that tracheotomy can be best done under chloroform (p. 319), the opinion being fortified in a footnote by a statement of Dr. Buchanan, of Glasgow, as to his favorable experience of the operation with the patient in an anæsthetic state. We have never ourselves seen any case in which its use led to a fatal result, but we are led to allude to this point of surgical practice from having seen in this JOURNAL, a short time ago, the suggestion that it might be advisable not to use ether when tracheotomy was performed for croup. Firmly convinced that the operation need not be more dangerous for being practised during etherization, we should be sorry to see parents and children debarred this priceless comfort.

Like all Englishmen, Mr. Holmes is very cautious in his denunciations of chloroform. But if half the unpleasant, and sometimes even dangerous symptoms which he speaks of as attending its inhalation (pp. 16 and 227) ever occurred with pure sulphuric ether, surgeons might be pitied indeed. As it is, our sympathies are only with the patients whose lives are unnecessarily exposed to the dangers of an anæsthetic the sole recommendation of which is its great convenience in use. A late New York journal brings us the report of two deaths in that city from chloroform, administered by the most experienced surgeons. Such events hasten the coming day of ether, but

it is to be regretted that its triumph should be attended by such a holocaust of victims.

Few surgeons have given so careful and sagacious study to the subject of Excision of Joints as Mr. Holmes. Excision of the hip he says he has performed a greater number of times than any one else, viz., in 19 instances. We give the result of these operations (p. 456):—

“6 died from the direct effect of the operation (in one case after amputation).

1 died after the operation, from the previous effects of the disease.

1 died of independent disease, some time after recovery from amputation.

2 recovered from the operation, but not from the disease, and died a long while afterwards.

2 were little if at all benefited.

1 (twice excised) was doubtful.

3 have useful limbs, but with sinuses.

3 recovered completely.”

The author evidently feels that this record requires a little special pleading, the mortality which it represents, 52·63 per cent., being, as will presently be shown, 12 per cent. greater than the latest exhibit of the death-rate of this operation in children. The most recent statistics, collated evidently with great care from all countries, are those of Dr. Good, of Paris (1869). They comprise 112 cases reported since 1860, of which 53·57 per cent. terminated fatally. Of the entire number, 59 occurred in children between 2 and 12 years of age; 40·67 per cent. of these were followed by a fatal result. But Dr. Good excludes from his table all those cases in which the cure was not verified after the operation, as well as those in which the cure was incomplete, including under this head persistent fistulous openings, even though the patient made use of the limb. Estimated with this degree of strictness, Mr. Holmes's cases (which would be reduced in number to thirteen) represent a mortality of 76·92 per cent. These figures indicate how cautiously cases should be selected, and that the indiscriminate performance of excision of the hip-joint can only bring a really valuable measure into disrepute. That increase of mortality has followed increased frequency of the operation is proved by the various tables of results collected during the past ten years. These show an advance from 36·30 per cent. (Fock, 1860) to 53·57 per cent. (Good, 1869).

It would be agreeable to quote from Mr. Holmes his sensible observations in regard to the very simple disease, necrosis, and

its treatment; topics which are now so frequently obscured by new nomenclature that one hardly recognizes, beneath their disguises, old acquaintances of long before the days of Ollier and Sédillot, but the length which this notice has already reached forbids its further extension.

We have selected for reference only a few subjects from this admirable volume, and lest anything we have said should be thought inconsistent with the high praise awarded to it at the outset of our remarks, we desire to close with the expression of opinion, that it is one of the best works on surgery produced of late years, being excellent for reference, judicious in doctrine, and elegant in style of composition.

*Surgical Cases.* By DAVID W. CHEEVER, M.D., Adjunct Professor of Clinical Surgery in Harvard University, Surgeon to the Boston City Hospital, Boston: printed for the Author. David Clapp & Son, 331 Washington St. 1869.

It is seldom that a small pamphlet of 33 pages contains the history of so many interesting and important cases as does the one recently published by Dr. Cheever.

The case of removal of an encephaloid tumor of tonsil derives peculiar interest from the circumstance that, while cancer of the tonsil is a very rare disease, and any operative interference for its relief still rarer, it is believed that this is the first instance where the tumor has been removed by external incision. The result is stated as follows:—

“In thirty-one days the wound had entirely closed. The pharynx was entirely clear; and, except that the pillars of the palate on the side affected were somewhat separated, it appeared in perfectly normal condition. The tongue was protruded in a straight line, and no paralysis of the lip remained.”

This would seem to encourage surgeons to attempt its removal by external incision in other cases of this disorder, in spite of the necessary depth of the wound, and obvious dangers attending the operation.

Two cases of naso-pharyngeal polypus, requiring the performance three times of Langenbeck's operation by depression and replacement of the superior maxilla. In the first case the polypus was removed by temporary depression of the right upper maxilla. The report states that in nineteen days the ligatures had all come away; there was no purulent discharge, and the bone was in excellent position and motion-

less. After thirty-five days he was discharged well.

Disease having returned, after eleven months, operation was repeated. Convalescence in this instance was rapid, and in twenty-seven days patient was discharged, with the wounds perfectly healed, and the bone firmly in place.

In the second case "the patient was treated in a manner novel as far as we know, the operation including both superior maxillary bones." Haemorrhage is reported as not excessive, but the shock of the operation is represented as considerable, and the succeeding symptoms as grave from that time. This patient, who is described as "feeble and anæmic from suffering and abstinence," died on the afternoon of the fifth day from the operation.

Two cases of reproduction of the tibia after excision are given. In the first there was "excision of the entire diaphysis and lower epiphysis of the tibia of a girl 13 years of age, for suppurative periostitis, followed by regeneration of the bone and a useful limb." In the second case "about five inches of the shaft were dissected out, and the extremities cut through with the chain saw. Recovery was excellent and continuous. A good limb resulted."

Eleven cases of excision of the head of the femur for "morbus coxarius" are given. "Of these, three died:—One adult, of exhaustion; one adult, of Bright's disease; one child, of tubercular meningitis. Four of these children are walking very well. The remaining four are still in bed, and under treatment."

These cases were all treated at the City Hospital, by Dr. Cheever and his colleagues.

†

*Uterine Catarrh frequently the Cause of Sterility—New Treatment.* By H. E. GAUTHLON, M.D. London, New York, Savannah, Paris, Philadelphia and Baltimore.

This is a pamphlet of about 80 pages, not closely written, and divided into chapters on the Anatomy, Pathology, Causes, Symptoms, Diagnosis, Prognosis and Treatment (by the new method) of Uterine Catarrh.

The author certainly deserves credit for his proficiency in the English language; for Frenchmen usually have much difficulty with foreign languages. Although one is rather too forcibly reminded that uterine treatments form a *specialty* to which the author devotes himself, there is a good deal of excellent common sense in each chapter.

But a few passages need comment. We are told on page 34 that uterine catarrh is dependent on a condition of the uterus "directly opposed to anything like inflammation"; and on page 35, that "the discharge which comes from the os uteri is often mixed with blood and pus."

On page 45, under the head of diagnosis, we are told that "there is no blood in uterine catarrh."

And although we do not profess any especial knowledge of this branch of medical research, we think that the paragraph on page 49, in which a most alarming picture of the occasional consequences of uterine catarrh is given, must be received with a certain amount of reservation.

Again, we are told that the diagnosis of the affection is perfectly easy; for the *discharge* must be seen with the speculum to proceed from the os; and in order to guide us in diagnosing cervical from uterine catarrh, we are told that, in the former, the sound does not readily pass the os internum, while in the latter case the whole muscular coat of the uterus is in a state of relaxation, which readily allows the sound to pass to the fundus.

We must be allowed to say that the chapter on diagnosis seems to us very deficient. Nothing is said about vaginal leucorrhœa, while it might properly be inferred that *uterine catarrh* was the most common of all ailments.

The "new treatment" advised consists of injections of a saturated solution of nitrate of silver, thrown up to the fundus uteri, retained there by a tampon, and repeated at intervals of from four to fifteen days or more. We are assured that no danger whatever is to be apprehended from the fluid passing into the peritoneum, and that no untoward effects ever follow this trifling operation, except in rare cases, such symptoms as "coldness of the extremities, swelling of the abdomen, smallness of the pulse, vomiting, and trembling of the limbs," "which give great alarm to inexperienced persons." We have had no experience with these injections; and would only say, that if proved harmless, they must be of benefit in many cases.

In reading the pamphlet, we think that we have noticed a similarity to some other French productions, in this respect, that the whole subject is made to appear entirely free from all difficulty, provided only that the rules of *M. Gauthlon* be attended to; and we have, in particular, been reminded of a small work on "*Les Amygdales*," by *M. Chassaignac*, in which it appears that

the enlargement of these organs is of altogether more frequent occurrence than has ever been supposed; and that the most alarming train of symptoms is apt to follow, unless the "amygdales" are at once extirpated in the way prescribed, and by means of the instrument invented by *M. Chassaig-nac*.

## Medical and Surgical Journal.

BOSTON: THURSDAY, JULY 1, 1869.

ADVERTISED MEDICINES:—THE TRAFFIC IN DRUGS. IS PHARMACY TO BECOME A SPECIALTY OF GENERAL MEDICINE?

In that portion of our work which consists in looking over the "exchanges," we are much encumbered with the extra pages which are laden with the advertisements of proprietary medicines. We have to thread our way through them in impatient search for the tables of contents. The annoyance stands next in degree to that of cutting the leaves to complete the work left unfinished by the book-binder. In selecting a medicinal preparation, a candidate for our favor would not have a better chance of being prescribed from its so getting in our way. And, we have learned to be doubly cautious about noticing in these pages any remedy that we may see blazoned in hypertrophied characters on the outside leaves of this or of any other Journal. Yet, though any practitioner of medicine who knows his business should have better ways of finding out where to get the best remedial agent than from the advertisements of interested parties, we suppose these advertisements pay, or they would not continue to be paid for.

But, what we are going to do about it? We ourselves do not direct the advertising department; and in one sense, we suppose, the publisher who gets the profit out of it may not be fully master of the situation. We encounter the grievance we complain of in handling all classes of medical periodicals—quarterly, monthly and weekly; and any publisher who should refuse to advertise proprietary medicines like his neighbors

would obviously hamper his means of competing with other journals. Further, when the publishers are not medical men, it would be difficult at present fully to control their action in the matter by outside pressure. Alas, that these things are so! But, we state things as they are, and not as we would have them. We have no remedy to suggest at this moment. We cannot even say whether the disease be self-limited. We may, however, inquire what pathological condition is behind this state of things. We are, therefore, naturally led to take a glimpse at the position of the trade in drugs.

As to the wholesale drug trade, we infer that dealers can get from the importers just as good articles as they are willing to pay for; but that the tendency is, to a certain extent, to cheapen the price and the article with it. This appears from a paper on Rhubarb by Dr. E. R. Squibb before the American Pharmaceutical Association at its annual meeting in 1868. After stating that the general market for this drug had run down in quality, he goes on to say:—

Now the point desired to be made is that if pharmacists were only willing to pay such prices now, rhubarb of a quality fully equal to the Russian in medicinal value might be had, and would soon be as plentiful as ever it was. In proof of this statement the writer can offer the fact that he has never been without rhubarb which was fully equal to the Russian in his judgment, and that his price until just now has never been above \$7.00, and is now \$8.00, in consequence of unusual scarcity of high grades in the foreign markets. As the writer has never imported more than one package direct, and that from London, but has always gone through importing houses, the prices paid have been higher than if the market was supplied for a general demand. The last two packages received are exhibited at this meeting in connection with this note. The first of these is a chest of 130 pounds, imported to special order from Bremen, by B. W. Bull & Co., of New York. This cost 10s. 6d. sterling, which with the duty and charges make it cost here \$3.75 gold or \$5.50 currency. The contents of this chest were separated in two equal parts without any selection, and every lump of one-half was opened and examined. On separating the unsound and discolored pieces, which are considered unfit for medicinal uses, they are found not to exceed 20 per cent. of the

whole. This, if deducted, brings the currency cost up to \$6.60, or with the labor of opening and selecting, say \$6.80. This furnishes a grade of rhubarb which will be pronounced by judges as unexceptionable, and which at \$8.00 per pound pays nearly 18 per cent. profit. In addition to this the 20 per cent. of rejected lumps yields by labor about 12 or 15 per cent. of its weight of sound rhubarb as good as the larger portion, only that it is in small fragments. This, when the labor of separating is charged upon it, increases the profit on the whole to over 20 per cent.

To illustrate the manner in which the market may be run down, he says:—

A distant druggist or a pharmacist wants rhubarb to supply the physicians of his neighborhood and his incidental sales, and he goes to a central market, or employs a broker there, who usually does better for him, in one sense, than he could do for himself. He finds a range of prices, which, though all low, vary very much. He looks at the root or the powder, as the case may be, and is apt to think the higher prices much too high for the slighter differences in appearance, for he rarely opens the lumps, or more than two or three of them, and the powders he must take upon faith or appearance. He never thinks of the prices being all far too low, but takes the lowest, and the merchant who has this makes the sale. A less fortunate neighbor and competitor of this merchant sees this and finds that he must buy his rhubarb lower next time. The time arrives, and he sees a lot which can be picked over, and the best of it dusted with some yellow powder will present a fair appearance, and the remainder can be made into a handsome powder by skillful millers. The price gets a shade lower and he buys. The importer of this may have sold the lot whose price successfully attracted the pharmacist, and thus made two sales where the importer of the better and unsuccessful quality only made one sale. Or, if both grades are held by the same importer he finds the lower one go off two to one. He says, "I have mistaken my market, and before these higher priced parcels are sold I must have some more of the lower, or my neighbors will get my trade away from me." His orders go out promptly with limitations which are sure to avoid the mistake for the future. And thus the common market is largely supplied, the lower grades going off rapidly, the higher grades with very slow sale and much trouble, while the highest disappear from the market, or are

only heard of once in a while through some "Miss Nancy" who is rather nice than wise.

Rhubarb is a very delicate and sensitive drug, and much of it bears evidence of having been gathered immature or at a wrong season, and much of it of having been spoiled in the drying, but far more appears to get damaged in the transportation, so that it is not improbable that a very small part only of the total product ever reaches the market in a normal condition. No matter how or where it is damaged, it must be sold, and if it can be properly "doctored" there is but little of it that cannot be made to sell pretty well, either upon faith and the reputation of the seller, or upon appearance, or upon both.

Impinging closely upon the regular wholesale business is the *quondam irregular* wholesale business of the manufacturers and venders of patent or proprietary medicines. We need not dwell upon this department of the subject; but may remark, in passing, that the market is controlled, as we are informed, in respect to certain drugs by those who purchase to make them up into their proprietary pills or potions. A hundred thousand dollars invested in advertising a single preparation into popular use, and the colossal fortunes with the "palatial mansions" of some of those who have made lucky hits in dosing the public stomach, give some idea of the extent of the outside trade under consideration. It is, however, the relation of the traffic in proprietary medicines to the retail dealers in drugs—to the pharmacists—which chiefly challenges our interest here.

Some of the pharmacists of this city enjoy the confidence of the profession to an unlimited extent. Most of us would feel it sufficient praise of our proficiency as medical practitioners if we were acknowledged to be as skillful and thorough in our walk as those pharmacists are considered to be in theirs. Yet who among them will tell you they do not deal more or less in proprietary medicines? The fact is, the druggist earns but a meagre pittance, comparatively, by putting up the prescriptions of physicians. Grant him one hundred per centum profit—that gives him on a dozen pills, say, which it takes him twenty minutes to compound, and for which he

charges twenty-five cents, twelve and a half cents for his net earning. In some cases the prescription business about pays the store-rent, while clerk-hire, the principal's own living, and surplus, are gained by the sale of fancy toilet-articles and *proprietary medicines*. A druggist in a western city undertook to be an old-fashioned apothecary, depending upon the recipe business, and announced that he was about to keep himself *integer vitiæ scelerisque purus* as regards patent medicines. Precisely how long he tried it we are unable to say, but we are told that at the end of a year he had as fine a stock of "proprietary medicines" as was to be found in his ilk.

But, we have not told all. It would appear that in some parts of the country the regular business of the pharmacist is becoming over-topped by the trade in proprietary medicinal articles. One of our profession—than whom there is no higher authority on this subject in the country—writes us this fact. A surgeon of his acquaintance told him that he went to many of the up-town fashionable pharmacists of New York in the vain search for three or four little round, fine sponges needed for a delicate operation; and that he must have seen during this search a display of more than one hundred thousand dollars worth of fancy goods and proprietary medicines ostentatiously exhibited. He found only two pieces of the sponge, and for these he was charged more than five times the wholesale value.

Thus far the American Pharmaceutical Association has not attempted to grapple with the evil. An admirable work it is doing in its efforts to break down the adulteration of drugs and to raise the standard of pharmacy. In these efforts it is stimulated by the influence of such men as Prof. W. Procter, Jr., the Editor of the *American Journal of Pharmacy*, and Dr. E. R. Squibb. Dr. Squibb has for more than twenty years past worked at the *Materia Medica* and Pharmacy as a kind of specialty. The perfection of his pharmaceutical preparations, put up in the light of chemical assay, has made them as it were classical. His zeal, however, for "the Art," and his self-abnegation in behalf of it,

are not sufficiently known outside of pharmaceutical circles. We might say more. But Dr. Squibb's aversion to publicity restrains us. Notwithstanding these good influences, the American Pharmaceutical Association has not, as a body, attempted to stem the wide-spread abuse we are speaking of—perhaps because too many of its members are helplessly involved in it.\*

The magnitude of the trade in proprietary medicines obviously grows out of the extensive demand for them. What are the causes of that demand? One source of it may, perhaps, be found in a false idea of economy—the patient in dread of the

\* Mr. Daniel C. Robbins, however, in his Report on the Drug Market at the meeting of the American Pharmaceutical Association in 1868, says:—

On account of recent decisions in our courts of law in favor of proprietary rights in secret remedies, or patent medicines, as they are improperly called, some kind of legislation is required for public protection against this class of articles, as they have rapidly increased in number and importance, within a few years, as articles of commerce. The market list of secret proprietary preparations in use in our country far exceeds, in number of articles, that of the list of officials in all our *Materia Medica*. It is generally conceded by our apothecaries that about one half of all their sales, in amount, to customers is derived from this source, and if it were possible to obtain reliable statistics of the *per capita* or total consumption of these compounds within the Union, the American people would awake, and put in chains a traffic that panders to many vices, that seldom hesitates at any imposture, and as a rule considers the deception of the public to be a legitimate business. Hair washes, called dyes or restoratives, are sold in immense quantities as purely vegetable preparations, when lead and other deleterious minerals make the substance of these. Quieting and soothing syrups are recommended and largely sold as harmless cordials or sedatives for infants, which are composed in good part of morphine, opiates or other powerful sedatives, which should never be administered without the knowledge of the parent or some competent person. The child, whose only defence consists in the power to cry, for whom resistance is a necessity for protection and for development, is drugged to sleep, growth is retarded, and the brain and nervous system permanently injured, because of the ignorance of the parent, alike of the laws of health and of the deleterious remedy, which is misrepresented in all its component parts. No restriction of any kind is imposed upon ignorant quackery, while the physician, before he can prescribe or practise medicine, must be educated and pass some examination, as also the regular apothecary, in most of the States, is obliged to label carefully, under stringent laws, all similar preparations. \* \* \*

It is believed more secret medicinal preparations are sold and consumed in the United States than in all other countries, as throughout the continent of Europe there are very stringent regulations in regard to the sale of "nostrums."

The following is from the *New York Times*:—

A bill has been favorably reported in the Legislature, providing for the inspection of patent or *quack* medicines. The inspectors are required to ascertain their ingredients, and report the same annually to the Legislature and to the State Medical Society. There is a law analogous to this in about every country of Europe, and it doubtless often prevents the sale of deadly or injurious substances as patent medicines. The public would be startled at the exhibitions of charlatanism if the composition of some of the popular nostrums was reported.

doctor's fee sometimes paying, we take it, more for his patent medicines than the physician's advice and prescription combined would amount to. Another source, doubtless, is a notion that the medicine, with its mysterious and sounding title, the merits of which many dignitaries of the land have certified to, has in it some newly discovered drug, or owes its alleged success to some happy combination of *simples* (as in one sense is probably often the fact), of which drug or combination its manufacturers alone are cognizant. Of course we who are behind the scenes know better.

A more weighty cause, however, of the proprietary medicine harvest we find in another direction. It has been well said that the mistakes of the philosopher of one period become the vulgar errors of a succeeding generation. The physician of a former day dealt out his doses with a liberal, an unsparing hand. The practitioner of the present time, trained to demand of every remedy ample proofs of its right to be used before he will trust it, is abstemious in his employment of drugs, and leaves much to nature. It is more comfortable for him to wait for the statute of limitations to take sway, than it is for his patient who has the suffering to bear, and who becomes impatient. Some of the public may have understood literally the hyperbole of our genial friend in the advance guard, who said that it were better for humanity if all the drugs were thrown into the sea, only he should pity the fishes! Well, the popular mind has got by tradition from our medical predecessors the notion that when people are sick they must keep swallowing pills, powders, or draughts. If the regular Faculty will not administer them with sufficient freedom, the sick man, or his friends for him, will buy them of whomever will sell them. The Homœopathic reaction, we suspect, was not altogether against the nauseous prescriptions of former days, but grew up, in part, from this desire to be constantly "taking something" for every ailment. The pellet of sugar of milk, with triturated moonshine combined, supplied this demand, and nature had a chance to show what she could do, when neither aided nor obstructed.

But, thus far even, we believe we have told but a part of the story. The grand fact, as we think, is that whenever there is disease mankind at large have an aptitude for remedies. Out of this desire (instinctive shall we say?) they cannot be reasoned, though they may be cheated by the classic charm, the transcendental mystery of the thirtieth dilution, or the Savage incantation. From Hippocrates to the Indian Medicine Man there have been those whose business it was, and is, to seek out such things as would promise to heal the aching frame.

To let our remarks, therefore, here gather to a head, a lesson we would draw from the above considerations is, that it is not for us to attempt to eradicate this universal tendency. We may prune it, we may guide it; but we must ourselves humbly follow the lead of nature. Acknowledge submissively that much that has been cherished in the past, as to supposed curative agents, has been erroneous — absurd; that the wheat has been outweighed by the chaff; that proposed remedies are now constantly being started, which have a run and then are forgotten, because tried in the balance they are found wanting. Yet, after all, it is plain to common sense, that we are in possession of some medication that is of sterling worth, while we are constantly adding to the list of drugs that assuage and ameliorate, if they do not cure; and finally, that in the very fact of the rigid analysis — the extended investigation to which every new remedy is subjected, we have the earnest that our armamentum of reliable weapons will be largely increased in the future. If we must eliminate the middle term from the *tuto, cito, et jucunde*, as applied to much of the medication that we have, or even expect soon to have at command, yet as to the remaining terms, we contend that they are applicable to considerable which we now possess; and we have reason to hope that their scope will be widely extended.

We have now glanced at the position of the wholesale drug market; at that of the pharmacist; and at the traffic in proprietary medicines. There has been another small class of extra-pharmaceutical pre-
